lands, so it must have left the State last in the lowlands. That necessitated the two great ice-lobes, one from the north and northwest and one from the northeast. The former occupied the basin of the Red river of the North and the Minnesota valley, and the latter the valley of Lake Superior with its western tributaries. These at length united in one general ice sheet, but when they retired they assumed again their lobate forms outlined by moraines, and finally allowed an uncovered interlobate area of the high lands about the region of the Upper Mississippi. By the growth of this uncovered area the ice lobes shrank to smaller dimensions and disappeared entirely, the latest to finally leave the State being the northeastern lobe.

The belt along which these ice lobes collided in the central part of the State can be traced by the overlapping and confusion in the characters of the drift, the northwestern drift being normally gray and the northeastern red. This belt he marked out in general as continuing from Rice county to St. Paul, thence northwestwardly to the region of Itasca lake where it turns eastward, passes along the range known as Giant's range, and leaves the State not far from the extremity of Pigeon point. Wherever these ice-lobes uncovered land that slopes northerly, or toward the ice itself, the discharged waters formed lakes whose outlets, beaches and areas are sometimes well known, the chief of which is Lake Agassiz, described by Mr. Warren Upham. Twenty-five other such lakes were defined by Professor Winchell within Minnesota, varying in elevation from 890 feet to 1,700 feet above sea level.

Mr. Upham, in his lecture on 'The Giants' Kettles in the Interstate Park,' stated in substance that within an area of two or three acres in the northern part of the Interstate Park are found about seventy rock potholes, or giants' kettles, as they may be called in agreement with their common designation in the languages of Germany, Sweden and Norway. This area of their abundant occurrence is unsurpassed in respect to their numbers, depth and difficulty of explanation, by any other locality in the world, although many places, as in Maine, nearly all the other New England States, the vicinity of Christiania, Norway, and the Glacier Garden in Lucerne, have very remarkable giants' kettles.

At Taylor's Falls they range in diameter from a foot or less to 25 feet, and in depth from one foot or a few feet to 65 feet and 84 feet, these being the depths to which two potholes 25 feet apart have been excavated and sounded, but without yet reaching to their bottoms. In many cases the ratio of diameter to depth is as 1 to 5 or 1 to 7 with nearly cylindric, but occasionally somewhat spiral or rifle-like, form. The rock is the very hard Keweenawan diabase, scarcely exceeded in hardness by any known rock. From many features of these giants' kettles, as notably their abrupt rims and the generally unworn adjoining rock surface, Mr. Upham attributed their erosion to torrent-falling through moulins, vertical shafts of the ice sheet which covered this region in the Glacial period. Some of these kettles were filled and covered by drift, but the greater number are empty, excepting scanty gravel at the bottom, with a few water-rounded boulders. The adequacy of moulin torrents to erode the smaller as well as the larger kettles is shown by small potholes of such origin, in some instances only about a foot or two in diameter and depth, on the high ridges and tops of hills and mountains in Maine, New Hampshire and Vermont.

The above is but a brief summary of these two very instructive lectures which were delivered to a large audience in the Academy Assembly Hall.

F. G. WARVELLE.

SHORTER ARTICLES.

CHIASMODON IN THE INDIAN OCEAN.

THE Indian government survey steamer *Investigator*, Captain T. H. Henning, R. N., commanding, which has recently been engaged in beam-trawling off Cuddalore and Point Calimere on the southeast coast of India, has obtained a small specimen of the rare deep-sea fish, *Chiasmodon niger* Johnson, from a depth of 1,100 fathoms.

This species has hitherto been known only from four localities in the Atlantic. It was first reported from the Madeira Islands in 1850,

but not fully described until 1863, when Johnson obtained another specimen in that locality. Two other specimens have since been found at the surface (near the island of Dominica and on the Lehave Bank). The *Challenger* took another with the trawl at a depth of 1,500 fathoms in the mid-Atlantic.

Chiasmodon is remarkable for its large mouth and distensible stomach, enabling it to swallow fishes larger than itself. For most of the foregoing specimens, naturalists are indebted to the inability of the fish to digest what it swallows, resulting in its death and appearance at the surface. H. M. SMITH.

U. S. FISH COMMISSION, WASHINGTON, D. C.

THE SAN JOSÉ SCALE PROBLEM AS COMPARED WITH THE ORANGE SCALE PROBLEM.

I WAS much interested in the communication of Professor Kellogg in the issue of SCIENCE for March 8, 1901. Of course the practical value of Mr. Kuwana's investigations is in the increased probability of our being able to import from Japan the natural enemies of the San José scale, and thus control the pest here, as was done in case of the *Icerya*. It is, therefore, of interest to see where we now stand in the matter of information, on which to base a second experiment in importing into this country parasitic enemies of scale insects. I copy the following lines from Professor Kellogg's communication:

* * * "It the [San José scale] is attacked by several enemies, Mr. Kuwana personally finding one chalcid, three lady-bird beetles and one moth, the larva of which feeds on the scale. Of these enemies the chalcid fly and one of the lady-bird beetles are everywhere common, and are effective checks to the increase of the scale. It is probable that the comparatively little injury produced by the scale in Japan, widespread as it is, is due to the presence of these natural enemies." * * *

By the side of this information may be placed the following, extracted from the Adelaide, South Australia 'Garden and Field' of November, 1887, by the late Mr. Frazer S. Crawford, who, from first to last, gave such efficient aid in bringing about the introduction of the Vedalia lady beetle that suppressed the Orange scale in California.

* * * "We have a few species of Coccinellidæ about Adelaide, but they are not very plentiful, and although one or more species attacks the *Icerya*, yet they are not very effective in keeping them under, as the following experiment proves. Three months ago I put in a glass bottle a small branch of a gooseberry tree, on which some forty or fifty adult Iceryas were clustered. On examining them subsequently I discovered two lady-bird larvæ, which have lived to the present time feasting on the *Icerya*, evidently contented with their quarters; but at the present time there are likewise a great number of young larvæ, lately hatched, running about, thus showing that the work of destruction has been very slow, and that even under such favorable circumstances the coccinellæ larvæ cannot cope with the productive power of the *Icerya*. Strange to say, a similar twig, covered with about the same number of adult females, was about the same date placed in a lemon tree, and a fortnight back every vestige of *Icerya* had disappeared. This clearance was gradual, but what has caused it I am at a loss to say." * * *

It must be remembered that this was written one year prior to Mr. Keoheles starting for Australia on his first trip. It will thus be seen that Mr. Kuwana has thrown a flood of light upon this problem which I can only look upon as very similar to the one in which *Icerya* was involved, and afterwards so effectually solved. As I read of the conditions of the San José scale in Japan, as relating to numbers and effect, it seemed to coincide exactly with the mental picture that I could not banish from me when I went over some infested nursery stock two or three years ago, just received direct from Japan. While I had practically nothing to do with the introduction of the *Vedalia*, I did examine many orange groves about Adelaide, South Australia, for the *Icerya* and found a similar condition—only here and there a solitary individual, at most two or three together.

We can make a *defensive* fight against the San José scale with whale oil soap, petroleum, the axe and fire, in fact we must do so, in order to save our orchards from ruin; but we shall never be able by these measures to do more than check the pest. If we ever expect to do more than this we must make an *offensive* fight and with natural enemies brought from the country where they are found doing their work and holding this pest perpetually below the danger line in point of numbers. F. M. WEBSTER.

WOOSTER, OHIO, March 12, 1901.

NOTE.—Since the above was written, Dr. Howard informs me that Mr. C. L. Marlatt sailed for Japan on March 5th, his mission being to collect and forward such natural enemies of the San José scale as he may find in that country.

F. M. W.

CURRENT NOTES ON METEOROLOGY.

CLIMATE OF ARGENTINA.

ONE of the most important publications on climatology issued in recent years is buried in the second census of the Argentine Republic (Buenos Aires, 1898. Tomo I. Cuarta Parte. *El Clima de la República Argentina,* por Gualterio G. Davis. Pp. 259–381). This monograph is printed with a mass of other material in the volumes of the Argentine Census. No reprints of it have been struck off and it has so far practically escaped notice. Mr. Walter G. Davis, who is well known as the Director of the Argentine Meteorological Office, has in this report given an admirable presentation of the chief climatic features of Argentina, and has included a series of isothermal, isobaric and isohyetal charts which are of unusual interest. The interest of Argentina from a climatological standpoint is chiefly due to the great extent of that country from north to south. On the north it extends just beyond the Tropic of Capricorn; on the south it reaches latitude 55°. The differences in the temperature and rainfall conditions over this extended territory are naturally very striking, and profoundly affect the natural products of the Republic and the occupations of its inhabitants. All the important climatologic elements are tabulated and discussed, and many excellent graphic representations are given, showing the correlations between the various elements at certain selected stations. But the most important matter in the report is the series of charts showing the distribution of temperature, pressure and rainfall. The data used are the latest, the most complete and the best obtainable. There are isothermal charts for spring, summer, autumn, winter and for the year (reduced to sea-level and without reduction to sea-level); isobaric and wind charts for the seasons and for the year, and a mean annual rainfall chart. These charts show, for the first time, the distribution of these various elements over the southern portion of South America, in detail, and on the basis of reliable data. The extraordinary decrease of pressure to the southward is perhaps the most striking feature shown on these charts. In each season, as well as for the year, the isobars in the southern part of the Argentine run closely parallel, almost due east and west. Mr. Davis's report is altogether an extremely valuable piece of work, which should certainly be reprinted and made generally available for the use of students of climatology.

MONTHLY WEATHER REVIEW.

THE November number of the *Monthly Weather Review* is particularly strong in papers dealing with climatological subjects. W. H. Alexander, Observer of the Weather Bureau on the island of St. Kitts, contributes an article on the 'Rainfall of the Island of St. Kitts, W. I.,' in which the effects of topography upon the amount of precipitation are clearly brought out. 'The Climate of Spokane, Wash.,' is discussed by Charles Stewart on the basis of eight years' records. A. G. McAdie contributes another paper on 'Fog Studies on Mount Tamalpais' (Cal.), which is illustrated by four excellent half-tones, the original photographs having been taken from the U. S. Weather Bureau Observatory on Mt. Tamalpais. The Section Directors of Colorado, Idaho, Montana, New Mexico, Utah and Wyoming discuss the question of 'The Water Supply for the Season of 1900 as Depending on Snowfall.'

NOTES.

THE *Monthly Review of the Iowa Weather and Crop Service* for December contains a paper on 'Climatology of Iowa,' by J. R. Sage, read before the State Horticultural Society, Dec. 13, 1900, and a discussion of the 'Losses by Hailstorms in 1900.' A table prepared by the officials of the Farmers' Mutual Hail Insurance Association shows that an aggregate of 2,202 farms, in 64 counties, suffered damage to the amount of over $140,000.

THE *Meteorologische Zeitschrift* for December contains an excellent brief summary, by Exner, of recent contributions to the study of atmos-

pheric electricity. A bibliography accompanies the article (Ueber neuere Untersuchungen auf dem Gebiete der atmosphärischen Elektricität).

R. DEC. WARD.

YELLOW FEVER.*

1. Sufficient search reveals the presence of a fine small bacillus in the organs of all fatal cases of yellow fever. We have found it in each of the fourteen cadavers examined for the purpose. In diameter the bacillus somewhat recalls that of the influenza bacillus; seen in the tissues; it is about 4μ in length.

2. This bacillus has been found in kidney, in spleen, in mesenteric portal and axillary † lymphatic glands, etc., taken from yellow fever cadavers directly after death. In the contents of the lower intestine apparently the same bacillus is found often in extraordinary preponderance over other micro-organisms. Preparations of the pieces of 'mucus,' which are usually, if not always, present in yellow fever stools, at times may almost present the appearance of 'pure culture.'

3. Preparations of the organs usually fail to show the presence of any other bacteria, whose absence is confirmed by the usual sterility of cultivation experiments.

4. It is probable that this same bacillus has been met with, but not recognized by three other observers. Dr. Sternberg ‡ has mentioned it; and he has also recorded the finding of similar organisms in material derived from Drs. Domingos Freire and Carmona y Valle; but he did not recognize its presence frequently, probably on account of the employment of insufficiently stringent staining technique.

5. It is probable that recognition has not been previously accorded to this bacillus by reason of the difficulty with which it takes up stains (especially methylene-blue), and by reason of the difficulty of establishing growths on artificial media.

6. The most successful staining reagent is carbolic fuchsin solution (Ziehl), diluted with 5-per-cent. phenol solution (to prevent accidental contamination during the long staining period) immersion for several hours, followed by differentiation in weak acetic acid. Two hours staining period may fail to reveal bacilli, which appear after 12 to 18 hours. The bacilli in the stools are often of greater length than those in the tissues, and they may stain rather more easily; naturally the same is true of cultures.

7. Since the bacilli are small and comparatively few in numbers they are difficult to find. To facilitate matters at our last two necropsies (14th and 15th) a method of sedimentation has been adopted. A considerable quantity of organ juice is emulsified with antiseptic solutions, minute precautions against contamination and for control being taken; the emulsion is shaken from time to time and allowed to settle. The method is successful and may form a ready means of preserving bacteria-containing material for future study. The best fluid for the purpose has yet to be worked out; hitherto normal saline with about one-fifth per cent. sublimate has been employed.

8. Pure growths of these bacilli are not obtained in ordinary aërobic and anaërobic culture tubes.

9. Some pure cultures have been obtained by placing whole mesenteric glands (cut out by means of the thermo-cautery) into broth under strict hydrogen atmosphere. Investigations into the necessary constitution of culture media for successful cultivation are in progress.

10. Much search was made for parasites of the nature of protozoa. We conclude that yellow fever is not due to this class of parasite. Our examinations were made on very fresh organ juices, blood, etc., taken at various stages of the disease, with and without centrifugalisation,* and on specimens fixed and stained in appropriate ways. We may add that we have sometimes examined the organs in a fresh state under the microscope within half an hour after death.

11. The endeavor to prove a man-to-man

* Abstract of interim report by Herbert E. Durham and (the late) Walter Myers to the Liverpool School of Tropical Medicine.

† We find these constantly enlarged and much injected, though whether this is specific we are not able to say.

‡ *Report on Etiology and Prevention of Yellow Fever*, 1890.

* We have found this sometimes useful in examining the blood of ague patients.

transference of yellow fever by means of a particular kind of gnat by the recent American Commission is hardly intelligible for bacillary disease. Moreover, it does not seem to be borne out by their experiments, nor does it appear to satisfy certain endemiological conditions. It is proposed to deal more fully with the endemiology and epidemiology of the disease on a later occasion.

12. We think that the evidence in favor of the etiological importance of the fine small bacillus is stronger than any that has yet been adduced for any other pretended 'yellow fever germ.' At the same time there is much further work to be done ere its final establishment can be claimed. The acquisition of a new intestinal bacterium would explain the immunity of the 'acclimatised.'*

THE NEW STAR IN PERSEUS. †

THE first news of Anderson's discovery of a new star in *Perseus* was received at this Observatory on February 24th. An examination of the region near the star, made that evening with the 40-inch telescope, failed to show any evidence of nebulosity, but the bright moonlight would have rendered a faint nebula invisible. At that time the magnitude of the star appeared to be about 0.5. Its color was yellow, with a decided reddish cast, very similar to that of *α Orionis*. Very little time was spent in examining the spectrum visually, as it was felt that photographs would be more valuable than drawings based on micrometer measures. We had fortunately just received a fresh supply of Erythro plates through the kindness of the International Color Photo Company of Chicago, and it was therefore possible to photograph the entire spectrum from $H\alpha$ to $H\iota$. Beyond this point in the ultra-violet the absorption of the 40-inch objective greatly enfeebles the spectrum, which is still further weakened by the lack of perfect achromatism in this region.

* The completion of the interim report, of which this is an abstract, was interrupted by the onset of attacks of yellow fever in both of us. The loss of my much-lamented colleague renders it advisable to submit the shortened report only for the time being.—H. E. D.

† From Bulletin No. 16 from the Yerkes Observatory of the University of Chicago.

Photographs of the spectrum were obtained by Mr. Ellerman on February 24, 25, 26, 27 and 28, March 4, 6 and 11. The comparison spectra which appear on these plates are those of titanium, hydrogen and sodium.

On February 24th and 25th Mr. Ritchey photographed the region of the *Nova* with the 40-inch telescope and color screen. In order to obtain a sufficient number of comparison stars the plates were given an exposure of one hour. The light of the *Nova* was intercepted by a small movable occulting disk, with which four (for the second plate, five) very brief exposures were given at intervals of about fifteen minutes. The total exposure for the *Nova* was probably about half a second. In the resulting photographs, the images of the *Nova* and the neighboring stars (of which more than forty appear in a region 12′ square) are small and appear to be well adapted for measurement. Through the kindness of Director Rees, these plates will be measured at the Columbia College Observatory. The position of the *Nova* was measured micrometrically by Professor Burnham on March 3d.

The wedge photometer used with the 40-inch telescope in the determination of standards of faint stellar magnitude has been employed by Mr. Parkhurst in measuring the brightness of the *Nova*. Hitherto objectives of one and two inches aperture have sufficed, but as the *Nova* decreases in brilliancy it will be followed with the 12-inch and 40-inch telescopes. A preliminary reduction gives the following magnitudes:

Date.	Mag.
1901, Feb. 25	1.0
" " 26	1.1
" " 27	2.0
" " 28	1.9
" Mar. 3	2.7
" " 4	2.8
" " 5	2.7
" " 6	3.1

A photograph of the spectrum (G 440) taken with the one prism spectrograph on February 28th has been measured by the writer. The resulting wave-lengths of the lines and bands, computed by the aid of Cornu-Hartmann formulæ, furnished data for attaching a scale to an enlargement of the photograph reproduced in the Bulletin.

Inspection of the photograph will show that the spectrum is very similar to the earlier spectrum of *Nova Aurigæ*. The hydrogen lines, notably C and F, are bright and very broad. The dark lines superposed upon them are probably reversals caused by the absorption of an outer layer of cooler gas at lower pressure.

On the more refrangible side the hydrogen lines are accompanied by dark lines, just as was the case with *Nova Aurigæ*. As Wilsing has shown, this is doubtless due to the great pressure under which the radiation occurs. The bright sodium line has broadened into a band, on which appear the two dark D lines. These appear on the photographs, and are clearly visible in visual observations with a three-prism spectroscope. As the titanium poles were moistened with a weak solution of sodium chloride, the comparison spectrum contains the bright sodium lines. Thus the motion of the star in the line of sight can be measured. Some preliminary determinations indicate that the *Nova* is moving away from the earth at a low velocity.

The helium line D_3 seems to be present as a dark line, lying close to the bright sodium band on the more refrangible side. The bright calcium lines H and K are notable for their great breadth and for the narrow lines of reversal which traverse them. The chief nebular line seems to be present (λ 5002 – 5041), and a fainter line or band (λ 4911 – 4988) covers the region of the second nebular line. The *b* group of magnesium is doubtless represented by the very bright band λ 5154 – 5204. The green coronal line (λ 5303) would fall near the more refrangible edge of a bright band in the spectrum of the *Nova*.

Further results, based upon measurements of photographs taken with the three-prism spectrograph, will be given in a subsequent paper.*

MARCH 12, 1901. GEORGE E. HALE.

SCIENTIFIC NOTES AND NEWS.

PROFESSOR S. W. STRATTON has, in view of his appointment as director of the Bureau of Standards, resigned his professorship in the University of Chicago. He will go abroad soon to study similar institutions in foreign countries.

PROFESSOR GEORGE FREDERICK WRIGHT, of Oberlin College, arrived in New York on March 22d, after his geological expedition round the world.

DR. LEON VAILLANT, professor of zoology at the Paris Museum of Natural History, has been elected a member of the Zoological Society of London in the room of the late Alphonse Milne-Edwards.

AT the banquet offered to M. Marey, the eminent French physiologist, by the Paris Club Scientia, to which we have already called attention, it was decided to present him with a medal, and a committee for this purpose has been appointed. Subscriptions may be sent to M. Masson, treasurer, 120 Boulevard Saint-Germain, Paris.

THE University of Glasgow will confer, on April 23d, its LL.D. on Dr. A. W. Rücker, secretary of the Royal Society.

DR. G. A. HANSEN, the discoverer of the lepra bacillus, will celebrate his 60th birthday on July 29th, and the occasion will be celebrated by the erection of a marble bust in the Lungegaard Hospital, Bergen, where he discovered the bacillus.

THE Society of Italian Agriculturists has awarded a special honor to Professor Grassi for his services to agriculture by his investigations on malaria.

DR. G. TORELLI, professor of mathematics at Palermo, has been awarded the mathematical prize of the Naples Academy of Sciences.

SECRETARY LONG has called a meeting of the Board of Visitors to the Naval Observatory in Washington on April 9th. The board, it will be remembered, consists of Mr. St. Clair McKelway, of the Brooklyn *Eagle*, President William R. Harper, of the University of Chicago, Professor Edward C. Pickering, of the Harvard College Observatory, Professor Asaph

* Note added March 18th. A comparison of photographs taken on March 4th and March 15th, shows that the dark lines on the more refrangible edge of the bright hydrogen lines continue to increase in sharpness. At first single and rather diffuse, they have become sharply defined double lines. The *b* line of magnesium is apparently decreasing in intensity, and the calcium line K is much fainter than before.

Hall, Jr., of the University of Michigan, Professor Charles A. Young, of Princeton University, and Professor Ormond Stone, of the University of Virginia.

CAPTAIN BERNIER was at Ottawa last week with a view to obtaining a grant from the Government for his polar expedition. He has also opened subscriptions in the principal Canadian cities. He estimates the cost of the expedition at $130,000.

THE amount of new blood on the recently elected Council of the Geological Society of London is not great, being confined to Prosfesor Theodore T. Groom and the Right Reverend J. Mitchinson, D.D. We see that Dr. Mitchinson was elected a Fellow only last year, but he was bishop of Barbados and is now master of Pembroke College, Oxford.

Dr. J. G. ADAMI, professor of pathology at McGill University, will attend the International Congress of Tuberculosis, to be held at London in July. He has been appointed vice-president of the section of pathology and bacteriology.

PROFESSORS ANDREW F. WEST and J. Mark Baldwin, of Princeton University, have been appointed delegates to the Ninth Jubilee of the University of Glasgow.

DR. EDWIN A. BARBER has been appointed secretary of the Pennsylvania Museum and School of Industrial Art and curator of the museum.

DR. ASAPH HALL has resigned from the Board of Managers of the Observatory of Yale University.

IT is reported that the Secretary of the Navy has decided not to order the trial by court-martial of Professor Stinson J. Brown against whom charges were filed by Capt. Charles H. Davis, Superintendent of the Naval Observatory, but has detached Professor Brown from duty at the Observatory and placed him on waiting orders. He will be detailed for duty elsewhere as soon as an assignment can be found. It is also reported that Captain Davis will probably be assigned to the command of a ship in the course of the summer.

MR. FRED J. ALLEN, of Auburn, N. Y., has been nominated by President McKinley as Commissioner of Patents in the place of Mr. C. H. Duell, who has resigned in order to resume private practice.

KING EDWARD VII. has signified to the President and Council of the Marine Biological Association his pleasure in becoming the patron of the Association.

M. ANTON CARLÉS is making progress with the model for the monument of Pasteur which is to be erected in his native town. In addition to the statue of Pasteur, which is said to be very effective, there is a model personifying science who holds a wreath of laurel towards Pasteur, and another figure of a woman holding two young children who are supposed to have been saved from death by Pasteur's discoveries.

DR. GEORGE PRATT STARKWEATHER, assistant professor of applied mechanics in the Sheffield Scientific School of Yale University, died at New Haven on March 21st. Dr. Starkweather graduated from the Sheffield Scientific School in 1891 and was last year promoted from an instructorship to an assistant professorship. He was only twenty-eight years of age.

DR. GEORGE T. FAIRCHILD, from 1879 to 1897 president of the Kansas State Agricultural College, died on March 16th, in his sixty-second year. He was at the time of his death professor of English Literature at Berea College.

DR. JOHN W. GRIFFITH, for several years senior physician to the Finsbury Dispensary and medical officer of health to Clerkenwell, died recently at Camberwell in his 82d year. He was best known to naturalists as part author of Griffith & Henfrey's 'Micrographic Dictionary.'

THE death is also announced of Mr. W. J. Williams, for many years clerical assistant to the secretary of the Zoological Society of London.

ALEXANDER MACFARLANE, M.A., D.Sc., LL.D., will deliver a course of six lectures entitled 'British Mathematicians of the Nineteenth Century,' at Lehigh University, beginning April 12, 1901. The life and work of the following will be presented in the order named: George Peacock (1791–1858); Augustus DeMorgan

(1806–1871); Sir William Rowan Hamilton (1805–1865); George Boole (1815–1864); Arthur Cayley (1821–1895); William Kingdon Clifford (1845–1879). Those interested are invited to attend. Tickets of admission can be secured by addressing Professor C. L. Thornburg at the University.

THE Newberry Research Fund from the income of funds raised by the Scientific Alliance, New York, has been increased by an addition of $50 by a gift of a friend of the Alliance. The award this year will amount to $100 by action of the Council of the Academy and will be made in geology or paleontology. Application should be sent immediately to Professor Henry F. Osborn, Columbia University, New York City.

THE following gentlemen have undertaken to be responsible for the indexing of the literature of Great Britain and Ireland for the International Catalogue of Scientific Literature in the subjects named: *Anatomy*—Professor G. D. Thane, University College, London; *General Biology*—Professor E. A. Minchin, University College, London; *Physiology* (including *Pharmacology*)—Dr. W. A. Osborne, Physiological Laboratory, University College, London, or to Professor W. D. Halliburton, King's College, London; *Experimental Pathology*—Dr. T. G. Brodie, Examination Hall, Victoria Embankment, London, W. C.; *Bacteriology*—Mr. S. G. Shattock, St. Thomas's Hospital Medical School, London, S. E.; *Experimental Psychology*—Dr. W. H. R. Rivers, St. John's College, Cambridge.

THE International Association of Academies will hold a meeting in Paris on April 16th.

THE fifth Triennial International Congress of Physiologists will be held at Turin from September 17th to 23rd in Professor Mosso's laboratory. There will be an exhibition of apparatus from September 14th to 23rd. Americans proposing to attend the Congress can address Professor F. S. Lee, Columbia University, New York City.

THE triennial convention of weather bureau officials will be held at Milwaukee, Wis., on August 27th to 29th.

A CIVIL SERVICE examination will be held on April 23d and 24th for the positions of geologist and assistant geologist in the Geological Survey for occasional service at a salary from $3 to $5 per diem.

ONE of the amendments to the Sundry Civil Appropriation Bill, passed by the fifty-sixth Congress, appropriated $35,000 for the erection of a laboratory for the investigation of infectious and contagious diseases and matters pertaining to the public health, under the direction of the surgeon-general. Five acres of land, on which is situated the Naval Museum of Hygiene, have been set apart for the building.

THE California Legislature has appropriated $100,000 for the State Board of Health to be used for the suppression of the plague. The Legislature has also passed a most extraordinary bill making it a felony to publish, by writing or printing, that Asiatic cholera or bubonic plague exists within the State unless the fact has been determined by the State Board of Health and entered upon its minutes. The San Francisco papers have apparently been only too ready to suppress information in regard to the plague in that City, and the passage of a bill of this character at the present time seems almost incredible. It has for a long time been known in medical circles that there have been cases of plague in the Chinese quarters in San Francisco, but the State authorities have denied their existence and have attempted to suppress any information in regard to the epidemic. It appears that Secretary Gage appointed some time since, in spite of the protest of the Governor of California, a commission to investigate the matter. This commission, consisting of Professor F. G. Novy, of the University of Michigan, Professor Simon Flexner, of the University of Pennsylvania and Professor L. F. Barker, of the University of Chicago, has made a thorough investigation and has presented a report which for the present has not been made public. In the meanwhile the Governor of California has sent a commission to Washington to protest against Federal interference, and has recommended a local investigation. It appears that the epidemic in San Francisco is but slight, but it will naturally be exaggerated by attempts to deny its existence for commercial reasons.

GOVERNOR VORHEES, of New Jersey, has

signed the Palisades Park bill and the Appropriation bill which carries an item of $50,000 to aid in the purpose of preserving the Palisades and in establishing an inter-State park along the top of the bluff on the high rocks.

SECRETARY WILSON has authorized Professor Willis L. Moore, chief of the Weather Bureau, to create three new forecasting divisions, under the general authority of the last appropriation act. These divisions have been selected as follows: New England, headquarters at Boston; Western Gulf States, headquarters at Galveston, and Central Rocky Mountain plateau, headquarters at Denver. This will make a total of seven forecasting divisions in the weather service.

THE steamship *Discovery*, built for the British Antarctic Expedition, was launched on March 21st, from the yards of the Dundee Shipbuilders' Company. We gave last week some account of the ship and the scientific staff of the expedition.

THE following item is from the New York *Evening Post* of March 20th: "Peculiar circumstances surround the case of William Wallace, ex-Superintendent of Buildings at the Museum of Natural History, who resigned by request on January 10th. A lawsuit is under way before Judge Marean in the Kings County Supreme Court, special term, to-day, in which Mr. Wallace is alleged to have borrowed money as an agent of the Museum and appropriated it to his own uses. This money, it is further alleged, was borrowed from the contractors who are at work on the new buildings of the Museum. Work has been stopped because Mr. Wallace is alleged to have made contracts which he had no power to make. In reply to those who associate the facts that Mr. Wallace had borrowed money of the contractors and had then arranged contracts with them, Comptroller Coler, William E. Dodge, and others who are acquainted with the affairs of the Museum maintain a serious silence. The matter has been put in the hands of Edward M. Shepard, and to him each person referred inquirers. Mr. Shepard explained to-day that an investigation into Mr. Wallace's affairs was being made by the Museum authorities. "What you want to know, I suppose, is Mr. Wallace's exact offence," said Mr. Shepard. "On that subject I cannot talk. The investigation, which will probably take three weeks, will establish that question. If Mr. Wallace has had any wrong doing with the contractors, it is so far a matter between themselves. This I will say, however, that if any contractor has lent money to Mr. Wallace, and then received contracts from Mr. Wallace's hands without the approval of the trustees, I do not think the contractor is in an enviable position, and I do not believe the contract would be legally valid."

WE learn from *Nature* that a small zoological expedition has started for the Malay Peninsula. It consists of Mr. N. Annandale, who was a member of the 'Skeat' expedition to the Siamese Malay States in 1899, and Mr. H. C. Robinson, hon. research assistant in the Zoological Department of University College, Liverpool. They intend to settle for a year in the native State of Jalor, near the east coast of Lower Siam, and to explore the neighborhood of Patani and Biseret. Collections will be made in all branches of natural history, while one of the special objects of the expedition is the study of the pre-Malayan tribes of Negrito stock who inhabit the center of the peninsula. A thorough investigation will also be made of the fauna—both living and extinct—of certain very large limestone caves which are found in the district, and are said to extend for great distances underground. The birds of the district will also be studied, and observations made on mimicry and allied phenomena. The ethnographical work ought to be interesting, since Jalor is on the borderland in which the Siamese and Malay races meet. Mr. Robinson is supplied with dredges and townets for the investigation of the marine fauna, and he proposes, by the method of pumping sea-water through fine silk nets, to make a collection of the surface plankton of the Red Sea and Indian Ocean on the voyage out.

ACCORDING to the New York *Evening Post*, Dr. W. A. Kuflewski, chairman of the Special Committee appointed by the Chicago Public Library Board to consider the advisability of sterilizing the books in the library for the purpose of preventing the spread of disease, re-

ported to the trustees at their meeting on February 18th, recommending that some system be adopted for freeing the pages of the volumes from bacilli. Dr. Kuflewski exhibited several glass tubes filled with germs taken from the pages of library books. The bacilli represented a hundred different poisons and germs of disease. He said that all the fifty books examined by him during the investigation were found to be more or less infected. He said there was no doubt that disease was spread by the books. He advised that a system of sterilizing the volumes by the dry process be adopted immediately.

THE New York *Evening Post* reports that the Hon. John Dryden, Ontario Minister of Agriculture, recently announced in the Legislature that a complete change of policy had been decided upon in regard to the efforts to stamp out the San José scale. It had been found that cutting down infected orchards would prove far too costly to be continued. To continue it would have meant an expenditure of nearly $500,000 as a partial compensation to fruit growers. The new policy is to educate fruit-growers to destroy the pest without cutting down the trees. Experiments indicated that by systematic work this could be accomplished.

THE collection of mounted birds at the University of Michigan, including nearly fifteen hundred specimens, has been rearranged. The birds that are native of Michigan are in three cases on the east side of the bird room. Those in the case farthest north are birds to be found north of Ann Arbor, those in the middle case birds in the neighborhood, and those in the third case birds living to the south of Ann Arbor. The west side of the bird room is occupied with cases containing specimens from many different parts of the world. These are scientifically arranged. Besides the specimens in the cases, thirty-six bird groups have been arranged. These are mounted in their natural surroundings, often with nest, eggs and young. Each group is a picture of bird life. In addition to the mounted specimens in the bird room of the museum, the University possesses nearly four thousand skins for use in scientific study in the class room.

UNIVERSITY AND EDUCATIONAL NEWS.

SIR WILLIAM MCDONALD has made another large gift to McGill University, namely $150,000, for endowments for the chair of chemistry, now held by Professor Harrington, and for the chair of botany, now held by Professor Penhallow, and for an addition to the endowment of the chair of physics now held by Professor Cox.

TEACHERS College, Columbia University, has received an anonymous gift of $100,000 for a building for its experimental school. The building will provide for 50 children in the kindergarten and 240 in the elementary grades, with special classes in sewing, cooking, manual training and music. There will also be a gymnasium, baths, library, reading rooms and accommodations for evening classes, club meetings and social gatherings for the people of the community. This experimental school of the Teachers College is, of course, in addition to the Horace Mann school for which a new building is in course of construction.

THE present Legislature of the State of California has passed measures of importance for the two great universities of the State, and these have been signed by the Governor. The sum of $200,000 was appropriated for the support of the University of California, and a further contingent appropriation of $50,000 was made. Stanford University was, as we have already noted, given additional power to accept and hold funds, and its property was in part exempted from taxation.

THE last session of the State Legislature voted to place the North Dakota Agricultural College upon a permanent and fixed income in place of the heretofore uncertain bi-annual appropriation. One-fifth mill is assessed upon all taxable property in the State for the support of the College. An appropriation of $50,000 was made for needed buildings and improvements, and $18,000 to meet current expenses until the mill tax becomes available. A new chemical laboratory is to be built during the present season.

IT is reported that German-American citizens of Baltimore will collect $100,000 toward the endowment of the Johns Hopkins University, and that $600,000 of the million dollar fund have been secured.

THE Chicago *Tribune* reports that the Armour Institute of Technology will be amalgamated with the University of Chicago. The property of the Institute is valued at about $3,000,000, and there are about 1,000 students in attendance.

AN anonymous gift of $60,000 has been made to Allegheny College, at Meadville, Pa., on condition that $140,000 in addition be collected.

THE late Charles A. Converse, of Norwich, has bequeathed about $200,000 for public purposes, including $80,000 to the Norwich Free Academy for an art collection.

MRS. CHARLOTTE T. GASSETTE has given $10,000 to Albion College, at Albion, Mich., for a library building.

THE Manufacturers' Association in New York has appropriated $2,000 for a scholarship. Information concerning the terms on which it will be awarded can be obtained by addressing Mr. James T. Hoile, secretary of the association, 196 Montague street, Brooklyn.

THE medical building and the south building of the Iowa State University have been destroyed by fire. The loss is estimated at $250,000, and is only in part covered by insurance.

IN regard to the troubles at the Royal Engineering College at Coopers Hill, Lord George Hamilton has now consented to let the Board of Visitors meet the dismissed professors. He has also added to the Board of Visitors representatives of the Universities of Oxford, Cambridge and London, who are to be members of a committee that will report upon the working, discipline and constitution of the College, and the relations of the visitors, president and teaching staff.

DURING the latter part of June Professor Geo. F. Atkinson will deliver a series of lectures on 'Nature Study' at the summer school of the University of North Carolina. The lectures will deal with topics on 'Plant Life' and will be given before teachers. Professor Atkinson will return to Ithaca, N. Y., in time to take charge of the botanical work in the summer school of Cornell University.

PROFESSOR FRANK A. FETTER has resigned his position at Stanford University to accept a professorship of political science at Cornell University.

DR. DAVID EUGENE SMITH, principal of the State Normal College, at Brockport, N. Y., has been appointed professor of mathematics in Teachers College, Columbia University. Dr. Smith was graduated from Syracuse University in 1881, and is well known for his series of mathematical text-books and writings on the teaching and history of mathematics.

CAPTAIN WILLIAM CROZIER, of the Ordnance Department, has declined the appointment as professor of natural and experimental philosophy at the U. S. Military Academy at West Point, N. Y.

PRESIDENT JEROME H. RAYMOND has resigned the presidency of the University of West Virginia at Morgantown. There have been troubles in the faculty, and, as we have already noticed, two of the members who were dismissed have brought suit against President Raymond. The regents of the university have, however, in accepting the resignation, paid a high tribute to the services of Dr. Raymond. Dr. Raymond is now going abroad and on his return will accept a chair in the University of Chicago.

THE statement that Dr. W. T. Jordan, of the University of Tennessee, has been offered the presidency of the University of Alabama is not correct as the trustees will not elect a president until their meeting in June. Dr. Jordan's name has, however, been prominently mentioned in connection with the position.

THE following lecturers have been appointed at Yale University: Dr. Henry F. Davies, lecturer on esthetics and patristic philosophy; George R. Montgomery, lecturer in philosophy; Dr. Stuart Rowe, lecturer in pedagogy; Dr. William M. Hess, lecturer in philosophy.

MR HERBERT F. ROBERTS, instructor in botany in Washington University, St. Louis, has been elected to the chair of botany in the Kansas State Agricultural College.

PROFESSOR ANTON. FREIHERR VON EISELSBERG, of Königsberg, has been chosen to succeed the late Professor Eduard Albert in the chair of surgery at Vienna.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, APRIL 5, 1901.

CONTENTS:

Observation and Experiment: PROFESSOR R. S. WOODWARD ... 521
On the Homologies and Probable Origin of the Embryo-sac: PROFESSOR GEO. F. ATKINSON ... 530
Natural History Work at the Marine Biological Laboratory, Wood's Holl: PROFESSOR C. O. WHITMAN ... 538
Christian Frederik Lütken: F. A. B. ... 540
Scientific Books:—
Progress of Forest Management in the Adirondacks: PROFESSOR V. M. SPALDING. *Willey's Zoological Results:* PROFESSOR G. H. PARKER. *Taylor on the Austin Dam:* PROFESSOR FREDERIC W. SIMONDS ... 542
Scientific Journals and Articles ... 545
Societies and Academies:—
Anthropological Society of Washington: DR. WALTER HOUGH. *Science Club of Upper Iowa University. Science Club of the University of Wisconsin:* PROFESSOR LOUIS KAHLENBERG. *Elisha Mitchell Scientific Society:* PROFESSOR CHAS. BASKERVILLE ... 547
Discussion and Correspondence:—
The Date of Rafinesque's Death: DR. R. ELLSWORTH CALL. *Lunar Halo:* C. M. BROOMALL 548
Shorter Articles:—
The Largest Known Dinosaur: DR. ELMER S. RIGGS. *A Recent Fault-Slip, Ogden Canyon, Utah:* PROFESSOR J. E. TALMAGE ... 549
Quotations:—
The U. S. Naval Observatory. Politics and State Universities ... 550
Current Notes on Physiography:—
Snake River Canyon; Alpine Morphology; New Zealand: PROFESSOR W. M. DAVIS ... 551
Contemporary Thermodynamic Efficiencies: PROFESSOR R. H. THURSTON ... 552
The U. S. Geological Survey ... 554
Scientific Notes and News ... 555
University and Educational News ... 560

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

*OBSERVATION AND EXPERIMENT.**

THE near coincidence of this anniversary meeting of the Academy with the end of the nineteenth and with the beginning of the twentieth century imposes peculiar and quite unexpected restrictions in the way of freedom of choice of a fitting subject for an address. Naturally one would like to pass in review some of the brilliant achievements of science in the past century, and perhaps forecast the still more brilliant advances that may be expected to mature in the present century. Especially might one feel tempted to present a semi-popular inventory of the more striking or recondite scientific events with which he is particularly familiar. But all this and more, strange as it may seem, has been done, or is being done, by the public press. Specialists in almost every branch of science have been employed to expound and to summarize the discoveries, the theories, and the useful applications which have rendered science, by common consent, the most important factor in the civilization of the nineteenth century. Statesmen, philosophers and divines are likewise sounding the praises of science and the scientific method with a warmth of recognition and with a stamp of approval which tend to make one who is

*Address of the President of the New York Academy of Sciences, read before the Academy on February 25, 1901.

old enough to have lived in the pre-scientific, as well as in the present epoch, feel as if a millennium were close at hand. Indeed, such a wealth of good scientific literature is just now thrust before us and such a wealth of praise is just now bestowed on scientific achievement that the modest man of science must hesitate before adding a word to that literature or a qualification to that praise.

The requirements of official position are remorseless, however, and one must speak his thought, although silence with respect to science may appear to be the most urgent need of the hour. In view of these circumstances, it seems best to avoid topics of current interest and to invite your attention to a brief consideration of the elements which lie at the basis of scientific investigation and scientific progress. A recurrence to the slow and painful beginnings of knowledge and the first principles evolved therefrom is always instructive; and it is especially fitting at a time, like the present, when the ardor of research is somewhat in danger of the sedative influences which spring from the popular glorification of triumphant successes.

The fundamental data from which all scientific knowledge grows are furnished by observation and experiment. After these come the higher steps of comparison, hypothesis, and finally the correlation and unification of phenomena under theory. Even pure mathematics, though long held apart from the other sciences, must be founded, I think, in the last analysis, on observation and experiment.

Of the infinite variety of phenomena which appeal to our senses, some, like those of sideral astronomy, are subject, in the main, to observation only; while others, like those of terrestrial physics, chemistry and biology, are subject to both observation and experiment. All phenomena are more or less entangled. They point backward and forward in time; any one of them appears and disappears only in connection with others; and the record any one of them leaves is known only by its interaction with others. Out of this plexus of relations and interrelations it is the business of science to discover the conditions of occurrence and the laws of continuity. Happily for man, although the ultimate complexity of phenomena is everywhere very great, it is frequently possible to discern those conditions and occasionally possible to trace out those laws. But the results we reach are essentially first approximations, depending, in general, on the extent to which we may ignore other phenomena than those specially considered. In fact, a first step towards the solution of a problem in science consists in determining how much of the universe may be safely left out of account. Thus the method of approximating to a knowledge of the laws, of nature is somewhat like the method of infinite series so much used by mathematicians in numerical calculations; and as it is a condition of success in the use of such series that they be convergent rather than divergent, so is it an essential of scientific sanity that the mind be restricted by observed facts rather than diverted by pleasing fancies.

The prime characteristic of the kind of knowledge that leads up to science is its dependence on facts which are permanent, and hence verifiable. In the course of the progress of our race there have been certain luminous epochs during which observers and experimentalists have revealed more or less of such knowledge. These epochs have been followed, generally, by others of comparative dullness, or positive darkness, during which fact has been replaced by fancy and what is permanent and verifiable has been eclipsed by what is ephemeral and illusory. It is my purpose

to-night to recall some of the principal events of these epochs, and to enforce, as well as I may, the great lesson they seem to teach us, namely, that science can be maintained only, and can be advanced only, by a constant appeal to observation and experiment.

As we look out on the universe about us the most striking phenomena visible are those which belong to what Galileo and his successors have fitly called 'the system of the world.' The rising and setting of the sun and moon; the majestic procession of the seasons; the splendid array of the stars in the heavens; the ebb and flow of the sea, and the never-ending variety from wind and weather, need only to be mentioned to enable us to understand why astronomy is at once the oldest and one of the most highly developed of the sciences. No classes of phenomena are so obvious, so omnipresent and so enduring. They have furnished the symbols of continuity and permanence for all languages in all historic times. The 'fixed stars,' for example, are in fact, as well as in fiction, our standards of reference in the reckoning of time and space; for are not 'Sirius and Orion and the Pleiades,' as Carlyle has remarked, 'still shining young and clear in their course as when the shepherds first noted them on the plains of Shinar?'

But before astronomy there were mythology and astrology, and we may well marvel how it has been possible, even after the lapse of twenty odd centuries, to educe the orderly precision of science out of the complicated miscellany of fiction, fact, religion, and politics bequeathed to our era by the fertile imaginations of our distinguished ancestors. What, for example, could be more confusing than the paleontological jungle called the stellar constellations, with its gods and godesses; with its dogs, lions, bears and fish, great and small, northern and southern; with its horse, whale and goat; and with the slimy forms of serpents intertwining them all?

Although it is impossible to set any date for the emergence of astronomy out of mythology and astrology, the epoch of Hipparchus undoubtedly is the earliest one of conspicuous advances known to us. This epoch, which may be called also the epoch of the Alexandrian school of science, extends from about 300 B.C. to about 150 A.D. It is distinguished by the remarkably perfect work in pure geometry of Euclid and Apollonius, and by the still more noteworthy work of Archimedes in laying the foundations of statics and hydrostatics; it comprises the measurements according to correct principles of the obliquity of the ecliptic and the dimensions of the earth by Eratosthenes; it includes the observations of the sun, moon, stars and planets collected by Aristyllus and Timocharis and later turned to so good account by Hipparchus; it embraces the work of Aristarchus, who maintained the heliocentric theory of the solar system and who was the first to attempt a measure of the dimensions of that system by means of the fine fact of observation that the earth, sun and moon form a right triangle, with the right angle at the moon when the latter is in dichotomy—or when its face is just half illuminated; and finally it includes the work of Ptolemy, a worthy disciple of Hipparchus, whose Almagest has come down to our own time.

From the observational point of view we must rank the principles with respect to fluids at rest discovered by Archimedes as amongst the capital contributions to the science of all times; for while his successors, of the last two centuries especially, have added to hydromechanics the large and vastly more difficult branch of hydrokinetics, they have found no change essential in his laws of hydrostatics.

Equally important, also, in its far reaching connections was the work of Eratosthenes in determining the size of the earth. This work required an hypothesis as to the shape of the earth and appropriate observations. Supposing the earth to be spherical, an assumption which Eratosthenes knew well how to justify, he saw that to determine its size it is only necessary to apply the rule of three to the measured length of an arc of a meridian and to the measured difference of the latitudes of the ends of such arc. He observed that at the city of Syene, which is about 500 miles south of Alexandria, the sun shone vertically downwards into deep wells at noon on the day of the summer solstice, showing thus that at that place and time the sun was in the zenith. On the same day at Alexandria he observed, by means of the gnomon, that the sun at noon was south of the zenith by one-fiftieth of a circle, or 7°.2. The distance between the two points was found by the royal road masters of the country to be 5,000 stadia, thus giving for the complete circumference of the earth 250,000 stadia. Although the measurements thus made by Eratosthenes were very crude and undoubtedly subject to large errors, we see in them the beginnings of some of the most refined geodetic operations of the present day. Unfortunately for us, also, the measurement of the distance is expressed in a unit whose relation to modern units is only roughly known.*

But commendable as was the work of his predecessors and contemporaries, the work of Hipparchus rises to a still higher plane. He was an observer and a theorist of the highest type, being able at once to collect facts and to interpret their relations, and he deserves to be ranked among the great astronomers of all times. He was the first to clearly appreciate the value of a catalogue of the fixed stars and constructed one giving the relative positions of 1,080 stars. He observed with surprising precision the interval of the tropical year; he made the first tables of the sun and moon; he discovered the remarkable fact of the precession of the equinoxes, and he thus early led the way to the great advances of modern times.

The peculiar merit of the work of Hipparchus lies not alone in the fact that he saw how the apparent motions of the heavenly bodies may be determined by observations, but also in the fact that he saw how these motions may be determined by a very small number of appropriate observations. Thus, for example, the interval from the vernal equinox to the summer solstice and the interval from the latter to the autumnal equinox sufficed to give him a close approximation to the apparent motion of the sun; while the records of a few eclipses of the moon enabled him to deduce a closely correct value of the precession of the equinoxes, that shifting of the line of intersection of the equator and the ecliptic which goes on so slowly that an interval of nearly 26,000 years is required for a complete circuit.

Hipparchus may be called the founder of the geocentric theory, since he demonstrated the accordance of the phenomena known to him with that theory. The fact that this theory is false detracts little from his merits; for the sole requisites of a good theory are simplicity of statement and conformity with observation. We now know, indeed, that mechanical phenomena are, in general, susceptible of multiple interpretations, and that

* As illustrating the slow growth of ideas with respect to precision, it may be related that when the Arabians in the ninth century undertook, for the same purpose, the measurement of a meridional arc on the plain of Singiar, in Mesopotamia, they were not more successful in preserving for posterity the standard of length used by them. This standard is said to have been the 'black cubit, which consists of 27 inches, each inch being the thickness of six grains of barley.'

observation must decide which of them is to be preferred.

The method which Hipparchus used to measure the sun's apparent motion among the fixed stars is very noteworthy, especially when we consider the utter lack of effective instruments in his time. If the sun moves regularly about the earth, as first supposed by Hipparchus, it ought to return at any epoch, as that of an equinox, to the same position among the fixed stars. Imagine a line drawn at the time of the vernal equinox, say, from the center of the earth to the center of the sun. This line prolonged will pierce the celestial sphere in two points, and, if either point can be located, the position of the sun with reference to the stars becomes known. Hipparchus fixed this position by noting the location among the stars of the center of the shadow cast by the earth at the times of eclipses of the moon. By a comparison of his own observations of such eclipses with those made by his predecessors he was able to determine the apparent motion of the sun with reference to the stars, or what we now know to be the motion of the equinoxes with reference to stars. To establish this fact of precession from such meager observations was a great step; and it seems not a little singular that a phenomenon so striking should not have led to speedy investigations for its source. But about eighteen centuries elapsed before Newton clearly visualized the mechanical interpretation of this phenomenon, and it was only after an additional half-century that the interpretation was fully worked out by d'Alembert.

How rapidly the spirit of science dies out when its devotees cease to observe and experiment is shown by the failure of the 'Divine School of Alexandria' to maintain the high standard set by Hipparchus. His immediate successors became at best only commentators. They wrote much but observed little; and it does not appear that any of them attempted even to verify the remarkable discoveries of Hipparchus during the two hundred and fifty years which elapsed between the period of his activity and the advent of his worthy disciple and expounder Ptolemy.

It is to the work of Ptolemy chiefly that we owe our knowledge of the discoveries and theories of the Hipparchian epoch. His treatise on the 'Great Construction,' the Megiste Syntaxis, or the Al Magisti and hence Almagest of the Arabians, is the earliest of the great systematic treatises on astronomy. It is in this work that the theory of eccentrics and epicycles of Hipparchus is explained and elaborated, and it is this work which has given the name of Ptolemy, rather than that of his acknowledged master, to a system of the world which dominated scientific thought for nearly fifteen hundred years.

The period during which the observations and researches of Ptolemy were carried on is commonly referred to in history as extending from the reign of the Emperor Hadrian to that of Marcus Aurelius. Thus, while Ptolemy was an Egyptian by birth, the fact that he was permitted to pursue his astronomical studies under the empire helps to some extent to relieve the Romans of the charge that they were, as regards science, the most ignorant people of antiquity. But the gravity of that charge is only palliated by the work of Ptolemy, for he left no successors. Roman astronomy did not rise above the level of astrology; the spirit of scientific enquiry gave way to speculation and declamation; and the long night which followed was not broken until the dawn of the epoch of Galileo—the modern epoch, whose advances have been founded on observation and experiment.

If astronomy is preeminent among the sciences for its dependence on observation, chemistry and physics are equally preemi-

nent for their dependence on experiment. This difference in methods of investigation between the former and the two latter sciences is a difference imposed by the circumstances that astronomy deals chiefly with objects at long range while chemistry and physics are concerned with objects near at hand. It seems not a little singular, however, at first thought, that progress in the development of knowledge concerning the behavior of distant bodies should have been almost as rapid up to the present time as the development of knowledge concerning bodies much more familiar and accessible to us.

Chemistry and physics, like astronomy, had their forerunners in mythological follies and extravagances. Semi-civilized and civilized man required a long time after he had learned how to talk and to write well, after he had founded states and constructed systems of philosophy and religion, before he could reason rationally and successfully with respect to the commonest material things about him. Thus, chemistry was long obscured by merely verbal speculations on the 'four elements, earth, air, fire and water' or on the 'three elements, salt, sulphur and mercury'; while the beginnings of physics were perhaps even more clouded by the fantastic unrealities of fertile but unchecked imaginations.

But man early learned to measure the value of chemistry by the 'gold standard.' It is hinted, in fact, though without adequate evidence, that the Golden Fleece of the Argonautic expedition was a manuscript containing valuable secrets of the chemist's art; and Suidas, of the eleventh century, to whom the word chemistry is attributed, relates that Diocletian, fearing that the Egyptians, by reason of their knowledge, might become rich and restive, ordered, in true Roman fashion, that their books on chemistry should be burned. The thirst for gold assisted also in the development of alchemy, which flourished from the eleventh to the fifteenth century especially, and has had not a few adherents, it would seem, during all the centuries down to and including the one just past. The philosopher's stone was almost universally believed to be a real agent in medieval times; and this strange fiction also has its survivals in the 'mad stones,' 'moon stones,' 'lucky stones,' and other 'charms' whose use even at the present time is not uncommonly justified by the wise saying that 'there may be something in them.'

The difficulty in getting the human mind started with the elements of physical science is well illustrated, likewise, by the superstitious rubbish that encumbered the early progress of knowledge concerning magnets. They were endowed with imaginary qualities far more wonderful than subsequent observation and experiment have disclosed. It was believed, for example, that they would cause some diseases and cure others; that they were effective as love philters; that they would lose their properties when rubbed with garlic (which seems not so unlikely), but that a bath in goat's blood would readily counteract this destructive effect. And in this case, also, as with alchemy and the philosopher's stone, it is to be noted that such crude notions of the phenomena of matter find their survivals at the present day in a wide acceptance of the unverified efficacy of 'magnetic healers' and 'electric belts,' and in the ease with which capitalists can be persuaded to invest in a 'Keely motor' or in anything that promises the marvelous.

With the decline of alchemy the field for chemistry shifted somewhat. Not unnaturally, since most chemists were also physicians in those days, a knowledge of the chemical properties of substances came to occupy a prominent place in the physician's art. Thus Paracelsus in the sixteenth century, cutting loose from the

teachings of Aristotle and Galen, boldly asserted that the true use of chemistry is not to make gold, but to prepare medicine; and he and his follower Van Helmont, in addition to attaining fame for skill in compounding remedies, were amongst the first to appreciate the true import of the processes of analysis and synthesis which came to be called in their day the spagyric art. Then followed the doctrine of the mutually neutralizing substances, acid and alkali; the fruitful hypothesis of elective attractions, or affinities; the ingenious, if erroneous, theory of phlogiston, and the more permanent theory of oxygen. All these led up through more and more searching experimentation to the first great epoch in the history of chemistry—the epoch of Lavoisier.

Among the early workers in the century preceding the epoch of Lavoisier the names of Becher and his disciple Stahl deserve especial mention, not only by reason of their introduction of the theory of phlogiston, but also by reason of their enthusiastic and steadfast devotion to science without hope of pecuniary reward. In his remarkable treatise entitled 'Physica Subterraneæ,' published in 1681, Becher defends the scientific pursuit of chemistry as not less worthy of attention than philosophical and theological studies. He insists especially on the need of careful observations and on the necessity of constantly verifying theory by experiment. With true scientific enthusiasm he describes the chemist as one willing to work amid the flames and fumes, and, if need be, the poisons and poverty of the laboratory. He has no patience with the charlatans, of which it appears there were still many in his day, who are looking chiefly for ways and means of extracting the precious from the baser metals. As for himself, he says: "My kingdom is not of this world. I trust that I have got hold of my pitcher by the right handle—the true method of treating this study; for the pseudo-chemists seek gold, but the true philosophers, science, which is more precious than any gold."

It is a peculiarly noteworthy fact that while much attention was given to chemistry during ancient and medieval times, comparatively little attention was given to the other branches of physical science. Our knowledge of heat, light, electricity and magnetism is almost wholly a development of modern times. The Greeks were acquainted with a few of the more elementary phenomena of electricity and light; and Ptolemy and Alhazen came near discovering the law of optical refraction; but there was no contribution made to either of those physical sciences comparable with the discoveries of Hipparchus in astronomy until the epoch of Galileo. What a marvelous increase in the rate of scientific progress began with this epoch is shown on nearly every page of the subsequent history of science. Galileo and his contemporaries may be said to have established the methods of observation and experiment. Their systematic application has borne fruit in every science. Almost every step forward has led to additional advances, until now each of the physical sciences has its wide array of determinate facts correlated under a great theory. In the domain of light, for example, the only solid contribution of the ancients is the obvious fact of radiation in straight lines. After nearly sixteen hundred years of our era had elapsed, there came Galileo's invention of the telescope, and about the same time Snell's discovery of the law of refraction. To the telescope was soon added the microscope and the camera obscura. Then followed Newton with explanations of the rainbow, dispersion and kindred phenomena; Hooke with his discovery of the colors of thin plates; Dolland with the

combination of two lenses to produce achromatism, and Huygens with his discoveries and explanations of double refraction and polarization; while in the meantime Roemer had measured the velocity of light. All these accessions crowded one another so closely that the emission theory of Newton and the undulatory theory of Huygens followed almost as a matter of necessity. The battle royal of these two rival theories, as you know, lasted for nearly a century, until the emission theory, by the sheer force of critical observations and experiments, was displaced by the undulatory theory through the brilliant researches of Young and Fresnel.

When we turn from the physical to the geological and biological sciences, the same lessons of the necessity and the efficiency of observation and experiment are still more strikingly apparent. For although geology and biology are the youngest of the grand divisions of science, they have accomplished more than all others toward giving man a proper orientation with respect to the rest of the universe. Geology as we now understand the term is but little more than a hundred years old, and biology, in the sense now attached to the word, is less than fifty years old. Nevertheless, these sciences have been the chief contributors to the doctrine of evolution, which, in view of the wide range of its applicability, must be regarded as the most important generalization of science.

It is a singular circumstance, however, considering the early advances made in the interpretation of the phenomena of astronomy, that the equally ubiquitous and far more accessible phenomena of geology and biology should have been so tardily investigated. The cause of this delay seems to lie in the fact, not without examples in the present day, that our remote ancestors had the habit of constructing their theories first and making their observations, if at all, afterwards; and in the cases of geology and biology they were so well satisfied with their theories that the trouble of making observations was for a long time dispensed with.

We of the present day have no right, perhaps—and I for one would not be disposed to use such a right if conceded—to blame our predecessors for the narrow, and in some instances crooked, views they held with regard to these subjects. But on the other hand, we shall fail, I think, to make proper use of our opportunities if we do not learn speedily to conduct scientific investigations in the future so as to avoid such colossal blunders as mar the history of geology and biology from its beginnings down almost to our own time.

As an illustration of the blunders referred to I may cite the profound reluctance, even of eminent men of science, to accept the plainest teachings of observation with respect to geological time up to the middle of the century just passed. Not until Lyell, the great champion of uniformitarianism as opposed to catastrophism, had published his 'Principles' (1830) did scientific opinion show a tendency to accept the fact of the hoary age of the earth, everywhere attested by the rocks in her crust.

And what a storm of opposition and condemnation, amounting almost in some cases to social ostracism, was visited by the very 'salt of the earth' against those who ventured during the sixties and the seventies of the last century to consider favorably the arguments of the 'Origin of Species'! All this has about it the freshness, and possibly the pain and the humor, of personal recollection for those of us who are old enough to have lived in two epochs. That a mistake of this sort could have been made thirty or forty years ago seems strange enough in these peaceful times of

ours. But while we may properly let the recollection of the storm and stress of this earlier period fade away, the moral of the conflict should be held up as a permanent warning to scientific as well as unscientific men; for no episode in the previous experience of the race demonstrates so clearly the sources of knowledge and the methods of attaining it.

As a final illustration of the validity of my thesis I would invite your attention to one of the most instructive and beneficent of the many brilliant biological researches of recent times. No one who has suffered from repeated attacks of intermittent fever, and has survived the ravages of the materia medica, can fail to take a lively interest in the wonderful progress made during the last twenty years towards a definite knowledge of the natural history of that disease. Nor can any one interested in the general aspects of science fail to see in the investigations leading up to this progress some of the finest examples of the scientific method.

It would appear that malarial fever has been one of the commonest disorders, in certain localities, with which man in his struggle for existence has had to cope; and before the discovery of the properties of Peruvian bark it must have been a very serious affliction by reason of its secondary if not by reason of its primary effects. The symptoms, course and distinguishing characteristics of the disease, as well as the remedies therefor, were long known, however, before it was suspected that the mosquito had anything to do with its dissemination. Bad water, foul air, and sudden or extreme changes of temperature were supposed to be promoting causes. The dampness of marshes, swamps and other areas holding stagnant water was held to be an especially common attendant, if not inducing, condition. There was, indeed, no lack of acute and painstaking observations and no lack of ingenious and well-supported hypotheses with regard to this widely prevalent but obscure disorder. The details of its diagnosis, prognosis, nature and causation, as laid down in the medical manuals of a few decades ago, are particularly interesting and instructive reading now in view of recent developments. For example, Hartshorne in his 'Essentials of the Principles and Practice of Medicine,' published in 1871, gives the following explanations:

"No disease has ordinarily so regular a succession of definite stages as intermittent fever, namely, the cold, the hot, and the sweating stage." * * * "Upon the origin of malarial fevers," he adds, "the following facts seem to be established: 1. They are reasonably designated as autumnal fevers, because very much the largest number of cases occur in the fall of the year. Spring has the next greatest number of cases. 2. They are always strictly localized in prevalence. 3. They never prevail in the thickly built portions of cities. 4. An average summer heat of at least 60° F. for two months is necessary for their development. Their violence and mortality are greatest, however, in tropical and subtropical climates. 5. They prevail least where the surface of the earth is rocky; and most near marshes, shallow lakes and slow streams. The vicinity of the sea is free from them, unless marshes lie near it. 6. The draining of dams or ponds, and the first culture of new soil, often originates them. 7. Their local prevalence in the autumn is always checked by a decided frost."

Here we have the facts with regard to the symptoms and cause of the disease stated with a clearness and a conciseness that could hardly be surpassed. But the real cause of the malady eluded the insight of the discriminating observers who collected those facts. A quite different class of facts required consideration. It was essential

to concentrate attention on the pathological aspects of the enquiry. As to the nature of the disease, Hartshorne writes, with commendable caution, "It is only possible to speculate at present. It is most probable that ague is a toxemic neurosis. The importance of the blood change attending it is shown by the disintegration of the blood corpuscles, and deposit of pigment in various organs." This destruction of the blood corpuscles was the critical point on which the investigation turned. About 1880, Laveran, a French army surgeon, discovered the destructive agency in a minute parasite, one of the protozoa, which takes up its residence in, and then, ungratefully enough, destroys, our red blood corpuscles. What a splendid problem was presented by the facts thus brought to light! The exquisite refinement of the researches which followed may be inferred when we reflect on the minuteness of an organism which can work out a part of its life history within blood corpuscles so small that four to six millions of them find plenty of room in a cubic millimeter. But stranger still is the fact, established within the past year or two, that the mosquito plays the rôle of an intermediary host and transmits the parasites to us while feasting upon our blood. The details of this remarkable discovery need only be alluded to here, for they have been so recently explained by the experts participating in them that their essential features are a part of popular information. Suffice it to remark that they show how we may secure almost complete immunity from malarial fevers at no distant day.

Thus, in whatever direction we look for the sources of scientific progress, the same elementary methods of advancement are found to be effective. Whether we consider the dimensions of the solar system or the distances between the molecules of a gas; whether we seek the history of a star as revealed by its light or the history of the earth as recorded in its crust; whether we would learn the evolution of man or the development of a protozoon; whether we would study the physical and chemical properties of the sun or the corresponding properties of a grain of sand; in short, whether we turn to the macrocosm or to the microcosm for definite, verifiable, knowledge, it is found to originate in and to advance with observation and experiment.

R. S. Woodward.

---

*ON THE HOMOLOGIES AND PROBABLE ORIGIN OF THE EMBRYO-SAC.**

The problems connected with the origin and interpretation of the embryo-sac have been of great interest to the student of plant morphology, from the time that they began to inquire into the relation of the ovule to the formation of the embryo plant. It is now a matter only of historical interest that Morland (1702), Geoffrey (1714) and others contended so seriously that the embryo-sac of the angiosperms was a sort of incubator where the embryo, brought in by the pollen tube, was hatched out into the young plantlet. While great advances have been made in our knowledge of the development and function of the embryo-sac, there are still unsettled problems of its origin and homology upon which we speculate, perhaps with no nearer approach to the truth than were the speculations by the founders of the science of plant morphology.

The first important contribution to the morphology of the embryo-sac was made by Hofmeister during the middle of the present (19th) century, extending over a period from 1849 (Die Entstehung des Embryo der Phanerogamen) to 1861 (Neue Beiträge zur Kenntniss der Phanerogamen). In the

* Paper presented before the joint session of Section G, American Association for the Advancement of Science, and the Botanical Society of America, at its sixth annual meeting, New York City, June 28, 1900.

embryo-sac when ready for fertilization he recognized two groups of nuclei lying respectively at the poles, which we now regard as the egg apparatus and the antipodals. At the micropylar end of the embryo-sac Hofmeister found usually two nuclei which he called 'germinal vesicles,' or 'embryonal vesicles,' one of which developed the embryo after the entrance of the pollen tube. In the opposite end he found a variable number of antipodal cells. The embryo-sac was by him considered homologous with the macrospore of the higher Pteridophytes. The germinal vesicles corresponded to the corpuscula (archegonia) and the accompanying rosette of cells (neck) in the gymnosperms.

Schacht (*Jahrb. f. wiss. Bot.*, 1857–8) believed that one of the germinal vesicles received the pollen tube and conveyed it later to the other, or that in some cases a third was present when two germinal vesicles seemed to convey the pollen tube to it. The germinal vesicles were sometimes marked on their surface by parallel folds, or in other cases there were parallel striæ in their contents. These striæ or folds formed his 'filiform apparatus,' which came later to be recognized by Strasburger, Pringsheim and others as homologous with the ventral canal cell of the pteridophytes. This gave rise to a further conception of the embryo-sac which was held by some down to a late period, and even appeared in some of the earlier editions of Sach's *Lehrbuch der Botanik*. In addition to the embryo-sac being a macrospore, it represented a prothallium in which the germinal vesicles formed the archegonia, while the antipodals formed the sterile remnant of the prothallium which was homologous with the endosperm of the gymnosperms.

In 1877–78 there appeared three works, by Strasburger, Warming and Vesque, which mark another important epoch in our knowledge of the embryo-sac. These were concerned with the development of the embryo-sac, and led to new and quite divergent views that have been presented from time to time since that period.

Strasburger (*Ueber Befruchtung und Zelltheilung*, 1877) gave the more complete account of the development of the embryo-sac and the origin of the endosperm, while Warming (De L'Ovule, *Ann. d. Sci. Nat. Bot.*, 6 ser., **5**) and Vesque (Développement du sac embryonnaire des phanerogames angiospermes, *Ibid.*, 6 series, bot. **6**, 1878) were more concerned with determining the origin of the embryo-sac in relation to its homologies with the pollen mother cells. It is not my intention to outline the history of the studies of the embryo-sac further, since it becomes very complex and would be filled with tedious detail. It is my purpose, however, to call attention to the principal theories that have been put forward in the interpretation of the homologies of the embryo-sac.

It should be borne in mind that in reviewing some of these theories of the embryo-sac which have been proposed from time to time, it is done in no spirit of criticism, nor for the purpose of holding up to view, at the present time, interpretations of morphological structures which the authors themselves may not now hold. Undoubtedly they were proposed by the authors as working hypotheses upon which to build further investigations, and it is certain that they all have been very useful in stimulating renewed and more profound researches, with improved methods of technique, and out of it all shall come in the future a clearer insight into the true meaning of these obscure plant structures. It is the history of all progressive science, that theories are proposed as working hypotheses, upon which to build further investigations into the nature of truth. When these have fallen new ones are formulated, for without some formulated idea in the mind, as a working

basis, not as something which we are striving to prove at all hazards, progress in investigation is impossible.

1. The first theory as we have seen was that proposed by Hofmeister who regarded the synergids and eggs as 'embryonal vesicles' or 'germinal vesicles,' and therefore the equivalent of eggs. The supposed variable number of antipodals when they were present represented the prothallium. It is interesting to note that at the present time a number of botanists are coming to recognize the synergids as potential eggs, thus confirming Hofmeister's interpretation of the egg apparatus.

2. The proposal by Schacht (1857–8) of a 'filiform apparatus' suggested by certain folds or striæ on the synergids, which were supposed to act as a conductor of the pollen tube to the egg, led Strasburger (Bef., p. 73, 1877), Pringsheim and others to recognize in this the ventral canal cell. The egg apparatus thus came to be recognized as the archegonium, with the synergids as neck cells, while the antipodals represented the prothallium. This was the prevailing view at that time, and was adopted by Sachs in the earlier editions of his text-book. A very similar view of the embryo-sac has recently been stated by Tretjakow.

3. The third view of the homology of the embryo-sac was the outgrowth of the studies of Warming and Vesque, in which the eight nuclei of the embryo-sac were interpreted as spores, the egg apparatus representing one tetrad, and the antipodals a second tetrad of spores, each spore homologous with the pollen grain. This had its origin in the endeavor of Warming to homologize the processes of cell division in the ovule with those in the anther, both of which were looked upon as sporangia. The larger cell which gives rise to the so-called axile row in the nucellus, and which is either the subepidermal cell, or a derivative of it when a 'tapetum' is present, he called the primordial mother cell of the embryo-sac, and it is so termed by some at the present day. This cell Warming recognized as the young archesporium, comparable with the tetrahedral cell in the young fern sporangium. This primordial mother cell, as is well known, divides into an axile row of several cells, 2, 3, 4, etc. This axile row Warming considered the mature archesporium, each cell being homologous with a pollen mother cell, and he termed them special mother cells. The lower one only developed into the embryo-sac, forming two tetrads, one at either pole, while the other special mother cells disappeared. The egg nucleus is then called the privileged spore. His conclusions here do not appear quite consistent with his hypothesis, since he derives two tetrads (8 spores) from a single special mother cell.

4. Vesque (1879), however, accepting in the main Warming's views, attempts to show that the two tetrads are derived from two special mother cells. The cells of the axile row he regards as the mature cells of the archesporium, that is, special mother cells, and numbers them 1, 2, 3, 4, 5, etc., according to the number present in different species, beginning with the uppermost cell (the one at the micropylar end). No. 1, then, the uppermost cell, divides to form a tetrad, the egg apparatus; while No. 2 forms one or several antipodals, and makes up the larger portion of the embryo-sac. The wall between 1 and 2 dissolves and disappears, so that the embryo-sac is supposed to form by the fusion of these two cells. It is not necessary to dwell further upon Vesque's view, since he gives such an imperfect account of the processes of development which take place here, and since subsequent studies show that in a very large majority of cases it is the lower cell of the axile row which gives rise to the embryo-sac. But it is of interest to note his attempt to harmonize Warming's view

of the relation of the special mother cells to the subsequent tetrads in the embryo-sac, the figure of the tetrad suggesting that each nucleus corresponds to a spore or pollen grain.

5. A fifth view, and one which was also influenced to some extent by Warming, was proposed by Marshall-Ward (*Jour. Micr. Soc.*, **20**, 1880; also, *Jour. Linn. Soc.*, 7, 1880). According to this view the embryo-sac consists of two prothallia, derived from two spores, the egg apparatus representing one, and the antipodals representing the second. The upper one consists of one vegetative cell (the upper polar nucleus) and the rudimentary archegonium, the two synergids being suggested as neck cells. The origin of the embryo-sac according to this view, was as follows: The primary mother cell of the embryo-sac, either a subepidermal cell, or the lower derivative of this, when a tapetum is formed, divides once and forms two cells. The lower one divides again, thus forming three cells in the axile row, separated by cell walls. These three cells correspond to the special mother cells which Warming believed to be homologous with the pollen mother cells. The lower cell now develops the embryo-sac. Its nucleus divides in the same direction as the division walls arising in the formation of the three cells of the axile row. These two nuclei at opposite poles of the young embryo-sac he believed represent cells in the axile row, thus making four cells in all. The two lower cells are not separated by cell walls, due, he believes, to the extraordinary rapidity of growth from this time onward. Each of these two lower cells, represented by the two-nucleated stage of the embryo-sac, he interpreted as a spore, one to give rise to the upper prothallium, and the other to the lower prothallium of the embryo-sac. It is possible to draw the inference that he regards the primary mother cell of the embryo-sac as a mother cell of four spores, since the axile row, as he interprets it, consists of four cells. The two lower ones he distinctly interprets as spores. The primary mother cell could not, however, be a cell homologous with the mother cell of spores according to this interpretation, since three successive divisions occur before these two spores are developed which are to form the embryo-sac; while the tetrad of real spores is developed by two successive divisions.

6. A sixth theory of the homology of the embryo-sac was proposed by Mann. (The embryo-sac of *Myosurus minimus* L., *Trans. & Proc. Bot. Soc.*, Edinburgh, **29**, 35; 1892. The embryo-sac of angiosperms is a sporocyte and not a macrospore, *Ann. Rep. B. A. A. S.*, 782, 1892.) He made an attempt to draw a direct homology between the embryo-sac and the pollen mother cell in origin, and also in the number of nuclei developed as a result of the division of the mother cell or sporocyte. For him each cell of the axile row is a sporocyte, and homologous with the pollen mother cell. Since from the pollen mother cell the four spores (pollen grains) are formed, and each pollen grain at maturity contains two nuclei, making eight in all, he traced a direct and parallel homology in the origin of the eight nuclei of the embryo-sac. The four-celled stage of the embryo-sac represents the four spores which are homologous with the four pollen grains. Each nucleus now divides again into a vegetative nucleus and a sexual nucleus, which correspond to the vegetative nucleus and generative nucleus of each pollen grain. In thus tracing the homology of the eight nuclei of the embryo-sac with the eight nuclei in the four pollen grains, Mann overlooks the fact that prior to fertilization, when the embryo-sac is still in the eight-nucleated stage, the generative cell in the pollen tube has divided again, *or in some cases it divides by the time the pollen is*

ripe, forming twelve nuclei for each pollen mother cell, instead of eight; and thus the homology falls.

7. Another view is that the embryo-sac, at the eight-nucleated stage, is homologous with the endosperm of the gymnosperms or, in other words, that the eight free cells are homologous with the endosperm of the gymnosperms. This was proposed by Strasburger as early as 1879. One of the cells of the endosperm forms the archegonium which here is very much more reduced than in the gymnosperms, being reduced to a single cell. A suggestion of such a reduced archegonium is found in Welwitschia, etc., where a single endosperm cell without division elongates to form the simple archegonium. Guinard ('81, *Ann. d. Sci. Nat. Bot.*) upholds this view.

8. Very closely allied to this view is the one which interprets all the cells at the eight-nuclear stage of the embryo-sac as potential eggs. Dodel ('91) found in *Iris siberica* that the synergids were sometimes fertilized, and developed embryos. He suggests that the synergids are potential eggs. Chamberlain, '95, suggests that one of the antipodals has all the appearance of an egg ready for fertilization. Strasburger (*Ang. und Gyn.*, '79) states that while in *Santalum* the normal number of eggs is two, there are sometimes three, and one of these may be the upper polar nucleus, when the endosperm is developed from the lower polar nucleus. Overton ('92) records a case of fertilization of one of the synergids of *Lilium martagon;* Guinard ('81) the development of embryos from two synergids in *Mimosa denhartii*, and Tretjakow ('95, *Ber. deut. Bot. Ges.*), the development of embryos from the antipodals of *Allium odorum*. Tretjakow interprets this as a case of apogamy, since he regards the antipodal cells as representing the vegetative portion of the prothallium.

In view of all the facts, Strasburger's hypothesis that the eight cells of the embryo-sac are homologous with the endosperm of the gymnosperms, seems the more reasonable one. If the synergids, then, can be fertilized and produce embryos, they too represent archegonia reduced to a single cell each. This would confirm the view first proposed by Hofmeister that the synergids and egg are 'germinal,' or 'embryonal vesicles.' Tretjakow holds that the antipodals represent the vegetative part of the prothallium, while the synergids and egg represent archegonia, which is very like the earlier views held by Strasburger, Pringsheim and others.

But if the eight cells of the embryo-sac are homologous with the endosperm of the gymnosperms, and the egg is an archegonium reduced to a single cell, it would seem that all the cells of the embryo-sac are potential eggs or potential archegonia.

It is probable that all the peripheral cells of the endosperm in the Abietineæ, for example, at a certain stage of development, a short time prior to fertilization, are potential archegonia. While the archegonia are usually developed from superficial cells at the micropylar end of the endosperm, they are frequently formed from superficial cells down on the side some distance from the end, giving to the endosperm in longitudinal section the appearance of a comb. Archegonia are in some cases developed at the opposite end of the endosperm which would correspond in position to the antipodals of then agiosperm-embryo-sac. Furthermore, archegonia are rarely developed from internal cells of the endosperm. This would indicate that prior to the time for fertilization all the cells of the endosperm are potential archegonia.

And this too seems reasonable since up to this time the course of development in all parts of the gymnosperm embryo-sac have been the same, all parts bear the same nutritive relation to the surrounding nucel-

lus. No part functions particularly as the vegetative part, or protonema, as is the case with most of the pteridophytes. The true vegetative function of the endosperm appears later. The fact that the archegonia do usually arise at the micropylar end of the endosperm is probably acquired or hereditary, since archegonia there are more certain to be fertilized.

If, therefore, the eight-celled stage of the angiosperm embryo-sac is homologous with the endosperm of the gymnosperms, then all the cells are potential eggs. The functional egg is at the micropylar end of the embryo-sac, because the chances for its being fertilized here are greater. This is true of the synergids also when they become functional eggs. The antipodals probably appear in this rôle very rarely. Nevertheless, potentially they are eggs, or greatly reduced archegonia. If this be so, then an embryo developing from an unfertilized antipodal cell would fall in the category of parthenogenesis, instead of apogamy.

This, however, may be drawing the line very fine, and I am not so much concerned with that fine distinction as I am with the *probable origin* of the embryo-sac. Since the embryo-sac has been recognized as the female prothallium of angiosperms, it is natural that there should be an effort to interpret it as a derivative from a macrospore. It is derived, according to the different interpretations of its homologies, from a different number of macrospores.

According to the Vesque theory, it consists of eight macrospores derived from two cells of the axile row, a fusion of two-spore mother cells. According to the theory proposed by Mann it consists of four macrospores and is derived from a single cell of the axile row, regarded as a spore mother cell (sporocyte). According to the theory suggested by Marshall Ward, it consists of two macrospores, each representing a prothallium of four nuclei, the two spores derived from the third cell in the axile row by a division in which no cross wall is formed. This cell of the axile row then would represent a *one-half spore mother cell*, or if the *number of divisions from the primary mother cell be taken into account it would represent a single spore.*

The theory that it consisted of eight spores was shown long ago by Guinard ('81) to be untenable. It necessitated the fusion of two spore mother cells. Vesque had little in support of his theory, since he considered the embryo-sac to be formed by a fusion of the two upper cells of the axile row, while as a matter of fact the embryo-sac arises from the lower cell in all except a very few cases. Although Marshall Ward found no evidence of a cell wall separating the two nuclei in the first division of the embryo-sac mother cell, he regarded these as representing two cells of the axile row.

There have been recent attempts to show that the embryo-sac in some cases is derived by a fusion of two cells of the axile row, where a weak or temporary cell wall is formed after the division of the nucleus (Wiegand, '98, in *Convallaria*). This, however, is more properly to be classed with the phenomenon so often exhibited in free-cell formation, where a temporary cell plate is laid down to be soon dissolved, and as often occurs in the first division of the pollen mother cell of different plants. Guinard ('81), in addition to citing this phenomenon as evidence that the embryo-sac is not formed by a fusion of two cells, adduces other strong evidence against it. In *Agraphis patula* (Mellink, '80) the axile row consists of two cells and the upper cell forms the embryo-sac, as Campbell ('99) has recently shown to be the case in *Peperomia pellucida*, while in Caltha, according to Mottier ('95), with a three-celled axile row, the upper one sometimes forms the embryo-sac. In *Narcissus tazetta* (Mellink, '80) there are two cells in the axile row.

The nucleus of the upper one undergoes repeated division without, however, forming the embryo-sac, which develops from the lower cell. Fischer ('80) reports a similar case in *Melica nutans* with an axile row of three cells ; the two upper ones each contain two nuclei, and yet the embryo-sac is developed from the lower. Similar cases Guinard ('80) found in *Cercis*, *Phaseolus*, *Erythrina*, Miss McKenney ('98) in *Scilla*, and Wiegand in *Convallaria* (1900). The cells of the axile row with several nuclei, Guinard points out, are undeveloped embryo-sacs. Their nuclei divide several times in adjacent cells, but the intervening walls do not dissolve and permit the fusion of the two cells of the axile row to form the embryo-sac, which is always developed from a single cell. Other examples are known, like that shown by Strasburger in *Rosa livida*, Benson in *Fagus* and *Carpinus*, where *several embryo-sacs side by side, or one above the other, begin to develop and attain considerable size, but do not fuse.*

The weight of evidence then goes to show that the embryo-sac is developed from a single cell of the axile row, though this row may consist of but a single subepidermal cell, as in *Lilium*, *Tulipa*, etc., or of two, three, or four cells, as in other types.

If this single cell, the mother cell of the embryo-sac, or macrospore, is the homologue of a spore in a strict morphological sense it would be necessary to show that it is derived by the same, or similar, processes of development. In those plants where the axile row consists of four cells, the cells might be regarded as tetrads, or spores, one of which develops the embryo-sac, while the others degenerate. But their axile arrangement, so constant in all spermaphytes, is against that supposition, and indicates that the course of development of these cells is more in keeping with the development of adjacent nucellar tissue. The axile arrangement itself, however, would not constitute a bar to their homology as spores. But in plants where the axile row consists of but two cells, or one cell, not even such a slight suggestion of their homology with spores is presented.

So far as investigation has been made, there is evidence that the development of spores in the bryophytes and pteridophytes, and in the development of the pollen in the spermaphytes, from a mother cell, is accompanied by nuclear phenomena known under the head of reduction of the chromosomes. It has been suggested that the reduction of the chromosomes in the formation of the embryo-sac might be employed as a criterion to determine what constitutes the spores. The facts, however, which have been obtained in the few cases investigated do not offer any more hopeful evidence as to the identity of the spores. In *Lilium*, and other observed cases, where the single cell develops directly into the embryo-sac, the reduction takes place in the first division. In other cases where an axile row of two, three or four cells is formed, the reduction of the chromosomes, so far as I know, always takes place in the primary mother cell of these, several cell divisions removed from the beginning of the embryo-sac. This is what we should expect, since this cell undergoes a maturation period prior to the formation of the axile row. So, whatever criterion we employ to determine the identity of the spores, we are led to irreconcilable confusion ; either that the embryo-sac just prior to fertilization consists of 1, 2, 4 or 8 spores, or that it is developed in some plants from a spore representing one-fourth of a mother cell or sporocyte ; in other plants from one-half of a mother cell, and in still others from the entire mother cell.

It is clear then that there do not exist here spores in the sense in which they are represented in the pteridophytes, or in the microspores of the spermaphytes ; neither in actual form, nor according to processes

of development. How then does the embryo-sac of angiosperms arise? It arises directly from the nucellar (sporangial) tissues or from the archesporium, without the intervention of spores. In the pteridophytes such phenomena are classed under the head of *apospory*. The origin of the embryo-sac directly from sporangial tissue, considered only from the standpoint of the absence of spores, would also fall under the general category of apospory. But apospory merely does not indicate the real morphological significance of its derivation. It is to be interpreted as an adaptation of the plant in developmental processes under the influence of the changed and peculiar environment of the gametophyte, which has become so general in the angiosperms, and probably in the gymnosperms also.

There is no longer any need of spores, as such, in the development of the female prothallium of angiosperms. Where spores exist, as such, they exist for the purpose of distribution of the plants, as in the bryophytes and pteridophytes; in the spermaphytes for the distribution of the male prothallia, so that they may be lodged in a position where the sperm cells may reach the egg. There is a law in the evolution of organisms and organs, that when an organ or structure is no longer needed as such, it tends to disappear. Spores are not needed in the development of the embryo-sac. They are therefore cut out of the cycle of development, and the embryo-sac, or gametophyte arises directly from the tissue of the sporophyte.

In suggesting that the origin of the embryo-sac is a kind of apospory, we do not mean that it is phylogenetically connected with cases of apospory in earlier forms, nor that it is derived from them, nor that apospory as a phenomenon is continuous through groups. We simply mean that there has been a shortening in the process of development here, before the formation of the spores, just as there has been a shortening after the beginning of the gametophyte, and it has gone so far that the spore, *as such, i. e.*, a spore which is formed by the accompaniment of the same phenomena which we know to prevail universally where we can recognize a definite spore, is *wanting*.

There is no need that such a spore or cell should be formed, because the necessity for it has disappeared. A cell, however, is formed which is not the morphological equivalent of a spore, but is the physiological equivalent, and develops the embryo-sac. The process is shortened so that the spore is cut out, and perhaps the mother cell forms the embryo-sac directly, a new development of a prothallium, or body functioning as such, directly from sporogenous tissue.

If Vines' suggestion (Student's Text-Book of Botany) that in *Asclepias* each cell of the pollinium is a mother cell, is correct, we should have a similar shortening process in the development of the male gametophyte. But this suggestion may not, possibly, be supported by the facts when we know the course of development of the pollinium and sperm cells in *Asclepias*. But we can conceive of a hypothetical case where a mechanism might arise for transporting the archesporium from an anther to the pistil bodily, and that the reduction in the anther had consequently gone so far that the tetrad divisions of the mother cell to form spores had ceased, now that there is no need for the individual and separate spore. The cell of the archesporium might form the pollen tube or male prothallium *directly*, cutting out the spore. This would be apospory so far as the loss of the spore is concerned. Its significance, however, would be greater. It would represent a new attainment in the evolution of the male gametophyte, quite independent of any phylogenetic relation to processes of development in earlier gametophytes.

The condition of things, however, in the ovule is very different from what it is in the anther, because early in the evolution of the spermaphytes the necessity for a definite spore for distribution disappeared, as the ovule retained the gametophyte within its nucellar tissue. The time has been long enough for the complete elimination of the spore. But in the case of the anther or microsporangium, the process has perhaps only begun; or perhaps it would be better to say that the conditions are being ushered in, in some cases where pollinia are formed, which in time may result in the elimination of the microspore from some of these forms.

In the elimination of the spore from the macrosporangium of the spermaphytes, they have arrived at a new morphological attainment, the development of the embryosac or gametophyte, directly from the archesporium or nucellus. The gametophyte of the angiosperms is very simple and rudimentary compared with that even of the gymnosperms, a few free cells, perhaps all of them potential eggs. Being free and few of them, they are in intimate relation with each other and are more subject to the secondary influences of fertilization than the endosperm cells of gymnosperms are.

Perhaps, for this reason, the angiosperms have arrived at a second and more remarkable morphological attainment, in the development of the second endosperm subsequent to fertilization. The interpretation of this may lie partly in the results of 'double fertilization,' and related phenomena, when the second sperm sometimes unites with one of the potential eggs, or with the 'endosperm nucleus' to form the second endosperm, or may possibly itself sometimes form a separate endosperm. It is well known that in the pteridophytes and gymnosperms often several eggs are fertilized in one prothallium, and several embryos begin to develop. Finally one of them usually outstrips the others, which then atrophy. In the angiosperm embryosac the potential eggs are all free and so situated that they are immediately and profoundly influenced by fertilization of the 'privileged' egg.

The endosperm nucleus, or one of the other potential eggs, being fertilized by the second sperm, may be so immediately influenced that, instead of developing into an embryo which in a short time would be outgrown and destroyed, it is directed into a new channel of development, which has resulted in the evolution of a new plant generation to be utilized as a nutrition body by the privileged embryo. If the secondary influences of fertilization in angiosperms have acted somewhat in this way, it might account not only for the retarded development of the so-called 'endosperm' in the angiosperms, but also for some of the phenomena known under the expression *Xenia*.

Geo. F. Atkinson.

NATURAL HISTORY WORK AT THE MARINE BIOLOGICAL LABORATORY, WOOD'S HOLL.

Natural history has been a growing element in the work of the Biological Laboratory at Wood's Holl. All departments represented at the Laboratory have made contributions in this field. Life histories have been studied principally in connection with embryological research, as, for example, in Conklin's work on 'Crepidula,' Lillie's on '*Unio*,' Mead's on 'Annelids,' Foot's on 'Allolobophora,' Clapp's on the 'Toad-fish,' Patten's on '*Limulus*,' Wheeler's on 'Insects,' Watasé's on the 'Fireflies,' etc. Within the last few years natural history studies have acquired wider and more independent interests with us. Animal behavior has engaged the attention of a number of investigators, led by Loeb, Wheeler, Thorndike and others. The demand for instruction followed the development of various lines of research, and the courses in general physiology and animal psy-

chology were, so to speak, spontaneous inevitables. The course in nature study, introduced for the first time last summer, furnished a typical illustration of the convergence of interests now cooperating at the Laboratory. Although the class only numbered fifteen members, over thirty investigators contributed to the instruction given, and a large share of the lectures, laboratory work and field studies were of the nature of research. Indeed, problems and demonstrations drawn from original work actually in progress, and presented by the investigators themselves, characterized the course throughout.

In the further development of this course in natural history, we are looking forward to hoped-for facilities far beyond our present realizations. The creation of a Natural History Farm at Wood's Holl may be somewhat remote still, nevertheless the project is entertained, and a small step has already been taken in anticipation. The columbarium now under cultivation is, I venture to hope, the first instalment of such a farm. This collection of pigeons, already the largest of the kind in existence, and rapidly increasing by accessions from all parts of the world, was undertaken with several ends in view. The pigeon group, containing between four and five hundred wild species, and not less than one hundred and fifty domestic species or varieties, offers one of the most favorable fields for the comparative study of variation and for experimentation in dealing with the problems of heredity and evolution. While the principal aim in making the collection was the investigation of problems, the farm project has been kept steadily in view. The columbarium would form one section of the farm, and exemplify its uses and unique advantages for every side of natural history.

Ever since the second birth of natural history in Darwin's 'Origin of Species,' the need of experimental work on *living* animals has been clearly seen. The two elements of success in such work are *control* and *continuity*. Both elements would be secured in an institution that combined efficiently organized laboratories and a farm stocked, manned and equipped for experimental research.

The idea of such an institution was elaborated a long time ago in the 'New Atlantis,' in which is described a model college and farm instituted for the experimental study and interpretation of nature. This model was esteemed too vast and high for imitation, and the great and marvelous things it promised only served to emphasize its dreamland picturesqueness. It was only after the doctrine of Natural Selection had taken a deep hold of the scientific world, that Lord Bacon's dream found an echo in the schemes proposed independently by Romanes and Varigny.

The question of the transmutation of species stood foremost in the minds of these naturalists, and it seemed as if the world would never be quite convinced without experimental tests of a crucial kind. For such tests it was obvious that plants and animals must be studied as living things; that the conditions of life and propagation must be such as could be precisely defined and made to vary in ways admitting of control; and that the work must be carried continuously forward from year to year. Out of these requirements arose the idea of an experimental farm.

General biology, or modern natural history, is now seen to stand in pressing need of something like the model college of Bacon's *Nova Atlantis*, embracing not only an experimental farm, but also laboratories and a strong body of investigators with a competent staff of assistants. Naturalists everywhere appear to be fully awake to this important need, and Professor Meldola (*Nature*, Feb. 13, 1896) did not ex-

press too strongly the general conviction when he declared—"The one great desideratum of modern biology is an experiment station where protracted observations can be carried on year after year on living animals."

The ideal plan would certainly make the farm an integral part of a natural history institute, according to the idea of the Baconian model; and herein may be seen the propriety of the name, 'Baconian Institute of Experimental Evolution,' proposed for such a foundation by Professor Osborn.*

An institute organized to meet the common needs of naturalists, and supported as a biological center—conditions approximated at Woods Holl—would obviously supply a strong combination of forces, and so ensure to a natural history farm its higher utilities as a source of scientific discovery and of unparalleled facilities for instruction.

C. O. Whitman.

CHRISTIAN FREDERIK LÜTKEN.†

The death of Professor Lütken of Copenhagen removes one of the last of that band of eminent zoologists whose long and active lives cast such luster on the Scandinavian countries throughout the last century.

Christian Frederik Lütken was born in Sor on October 4, 1827, the son of Professor Johannes Christian Lütken, Reader in Philosophy at the Academy there. It was during his last year's study at the Academy, which he entered in 1844, that young Lütken was induced by the lectures of Hauch and Steenstrup to turn seriously to zoology; and this he pursued when he passed to the University of Copenhagen in 1846. There he came in contact with Liebmann, Forchhammer, Ibsen, Eschircht, H. C. Oersted, and again Steenstrup, who was in the same year appointed professor of zoology at the University. Lütken's zoological studies were, however, interrupted by the troubles of 1849–50 (first Schleswig-Holstein war), when he served as a volunteer and took part in the battles of Ullerup and Isted. He was accorded permission to complete and publish his first scientific work during the winter 1849–50, and in 1852 finally left the army to fill a place as assistant in the Zoological Museum of the University, taking the degree of Magister in the following year. The position at the small University Museum was neither assured nor well paid, but it was improved some ten years later, when the Royal Museum was joined with that of the University to form the existing Museum of Natural History, in the second division of which (dealing with fish and lower animals, except Arthropoda) Lütken served as assistant to Steenstrup. It was not till the death of J. Reinhart in 1882 that he obtained an independent appointment as Inspector of the First Division, which was now made to include all vertebrates. After Steenstrup's retirement, on January 28, 1885, Lütken was appointed professor of zoology at the University and thus became chairman of the Museum Board, while he continued to direct the Division of Vertebrata. In 1885 he married his cousin Mathea Elizabeth Müller, who died in 1890, leaving no children. Some five years later Lütken's own energies began to yield to attacks of illness; in the summer of 1898 he had a paralytic stroke from which he never recovered; he therefore retired from his official posts at the beginning of 1899, and after a long struggle finally succumbed on the 6th of February at the age of 73.

Lütken's labors fall under the heads of museum work, education and descriptive zoology.

The Zoological Museum of Copenhagen,

* 'From the Greeks to Darwin,' p. 93.

† Much of the personal matter in this notice is gleaned from an article by H. F. E. Jungersen in *Illustreret Tidende* (Copenhagen) for February 17th. The article is accompanied by an excellent portrait.

with which he was connected for 47 years, is greatly indebted to his organizing power, and was constantly benefited by the friendly relations that he maintained with his colleagues in other lands. This was the branch of his work for which he was peculiarly fitted by his patience and accuracy, and to which he was most attracted. Among the gifts which, from very slender means, he contrived to make to the museum may be mentioned a valuable collection of fossil mammals.

For a teacher, and particularly a lecturer, Lütken was less qualified. His manner was reserved and unsympathetic, his style too literary. These defects were scarcely counterbalanced by the thoroughness with which he prepared his lectures. His great text-book, 'Dyre-riget,' published in 1855, was stuffed full of facts, laboriously collected and verified, but lacked the simplicity required in an educational work. This fault was remedied in the briefer manuals familiar throughout Danish schools as 'Lütkens, Nos. 2 and 3.' Indeed, as a writer for the public, Lütken could be clear enough. In addition to many popular sketches of animal life, he, together with C. Fogh and Chr. Vaupell, edited the 'Tidskrift for populære Fremstillinger af Naturvidenskaben,' which had a remarkably long life for a magazine of that nature, namely from 1854 to 1883. This literary interest took him away from the open-air studies of marine zoology that he had begun in his student days, while his museum duties led him still more to the 'dry bones' of his subject. Recognizing his own deficiencies, he succeeded in obtaining an annual grant for the founding of a Biological Station, where, under the guidance of younger men, his students could take a biological course. As a member of the Fishery Board also he successfully urged on the Government the need for a detailed study of the natural conditions of Danish waters before any legislation could be effective.

As a museum assistant Lütken's technical zoological writings were inevitably confined to the description and classification of the material in his charge. Corals, jellyfish, crustaceans, isopods, annelids, ascidians, blindworms, all came beneath his survey, but his chief work lay among echinoderms and fishes. In the former group his doctoral thesis 'On the Echinodermata of Greenland, and the geographical and bathymetric distribution of that class in northern seas' (1857) holds a foremost place. He wrote also on starfish, sea-urchins and West Indian crinoids, but his chief systematic work was done on the ophiurids. In this department he has of late found an able fellow-worker in Dr. Th. Mortensen. In ichthyology his earliest work of importance was on the classification of the Ganoids, the complete memoir appearing in 'Palæontographica' (1873–75). While describing and classifying the numerous fish that came to him from all parts, but chiefly from northern seas, he was by no means unmindful of wider questions, as was proved by his most important work 'Spolia Atlantica,' of which the first part, published in 1880, discussed the changes of form in fish during their growth and development. The second part, issued in 1892, dealt with the distribution of the phosphorescent patches in certain deep-sea fishes, and is thus alluded to by Goode and Bean in 'Oceanic Ichthyology': "Dr. Lütken's masterly and exhaustive paper on the Scopelids of the Zoological Museum of the University of Copenhagen * * * has rendered it necessary to completely revise our opinions upon the relations of the species."

All Lütken's work, like that of so many of his Scandinavian contemporaries, was marked by thoroughness, accuracy and a wide knowledge of previous writings. Al-

though well acquainted with foreign languages and a writer of good English (as proved by his contributions to the *Zoological Record* from 1872 to 1878, and by his admirable article on Steenstrup in *Natural Science* for September (1897), he preferred, as a rule, to publish in his native language. This, while a benefit to the Danish school, has not prevented foreign zoologists from recognizing the value of Lütken's work; abstracts have appeared in many English and other journals, and honors have been showered on the author. His death causes a vacancy in such societies as the Royal, Linnean and Zoological Societies of London, the Imperial Academy of Sciences of St. Petersburg, the Imperial and Royal Zoological and Botanical Society of Vienna, the Boston Society of Natural History and a vast number for whose names we have no space.

Lütken was a tall and handsome man of the fair Danish type, with a keen blue eye. His upright and somewhat stiff demeanor might be a reminiscence of his military service. But his reserve did not prevent one from seeing the thorough worth and single-mindedness of his life and thought, nor did it check his really kind disposition, as experienced not only by his family and closer friends, but by every foreign visitor to him in his Museum at Copenhagen, and every correspondent who sought his aid.

SCIENTIFIC BOOKS.

PROGRESS OF FOREST MANAGEMENT IN THE ADIRONDACKS.*

THE recent report of the Director of the New York State College of Forestry and the College Forest in the Adirondacks is a document of more than ordinary interest, dealing as it does with questions that are now engaging the attention of the legislatures of several States and to which much thought is being given by citizens who are interested in the public welfare.

As shown by the report, the number of students has increased from four, the number three years ago, to twenty-five and, in addition to these regular students, there are registered twenty-nine from the Colleges of Architecture, Civil Engineering and Agriculture. The five students who went out from the school last year have found satisfactory employment, three with the Forestry Division of the United States Department of Agriculture, one with a lumberman's firm and one with the Forest, Fish and Game Commission of the State of New York.

In addition to the work of the three professors of forestry, many of the professors and instructors in other Colleges of Cornell University have aided in giving instruction, and lectures on fish culture have been given by Dr. B. W. Evermann, of the United States Fish Commission, and a short course in practical timber-estimating was given at Axton by Mr. C. P. Whitney, a well-known estimator, while courses on marketing the forest crop, as well as special courses in law and engineering, have been arranged for.

The plan of requiring practical work of the junior and senior classes in the College Forest has proved satisfactory and has become a permanent arrangement. The work embraces inspection of logging operations, timber estimating and measuring, surveying and locating roads, nursery work and planting, marking trees for cutting, practical work in the sugar orchard, and excursions to fishing grounds and hatchery.

Aside from this, the distinctively educational work of the College, the problem of the management, development and satisfactory utilization of the forest property — thirty thousand acres in the Adirondacks—with which the College is entrusted has been fairly met. It involves securing a market for the wood, much of it already past maturity and rapidly deteriorating, and the perpetual renewal of the forest by planting or natural regeneration, so as to provide both for future cutting and improvement of the property. The widely different conditions under which European forestry is prac-

* Third Annual Report of the Director of the New York State College of Forestry, Ithaca, N. Y., March, 1901.

ticed make it an impossible guide in the present case, except as to principles, while the manner of their application has taken perforce the form of original experimental study of a most difficult problem.

The director ably defends the policy of harvesting the crop as carried out at the College Forest, a policy made possible by special legislation, which has permitted the entering into contracts for the disposal of the old and decrepit hardwoods forming the bulk of the culled forest. Such contract has been made with the Brooklyn Cooperage Company, under which a stave and heading factory and a wood alcohol plant are being erected at Tupper Lake and connected by rail with the College forest. The prices obtained are fair market rates, better than private owners of similar property in the Adirondacks have been able to get the present year, and the experiment, in spite of an unusually unfavorable winter, promises to be self-supporting. It is expected that about 50 per cent. of the area cut over during the time covered by the report will have to be planted. White pine and Norway spruce will be employed, using both plants and seeds, and adding elm and ash, with a few other species.

Various important questions have arisen in connection with the actual and possible yield of Adirondack hardwoods, and these, together with the ideals and practical limitations of American forestry, are carefully discussed. It is shown that the American market is the essential factor which makes the practice of forestry as a business different in the United States from that of Germany, and that this, again, is due to the difference in density and distribution of population. Accordingly, the German wood market is mostly local, steady and continuous. A sustained annual yield is the best business policy, and a thorough utilization down to the small brush is possible through local consumption by the dense poor population. The American wood market, on the other hand, is essentially continental; the harvest is transported to centers of consumption, and cheap transportation over long distances is the keynote of marketing it profitably. This requirement in many districts rules out a thorough utilization of the product, and inferior parts of the harvest must be left unused. Hence a realization of the theoretically 'normal forest' with a so-called 'sustained yield' is at present impracticable in America from a business point of view. And, moreover, unfair systems of taxation discourage the attempts at such management that otherwise might be made. The working plan of the College, therefore—carrying out the aim of the management to attain the best that is attainable under existing conditions—is simply to remove the old crop as fast as the market and practical considerations permit, and replace it by a crop of better composition and promise; *that is, to practice silviculture.*

The basis of an American system of forestry is summed up in three primary essentials:

1. Better protection of forest property, including rational methods of taxation—a subject of legislation.

2. More thorough utilization of the forest crop—a subject of wood technology and development of means of transportation and harvesting.

3. Silvicultural methods of harvesting, so as to produce a desirable new crop, or else artificial reforestation—the main concern of forestry.

Planting operations on burnt areas have been continued and there are now ninety-five acres planted, chiefly with white pine, Douglas spruce and Norway spruce, the last named having thus far proved most satisfactory as to cheapness, rapidity of growth and endurance of drought and frost. Two nurseries have been established in which already about a million seedlings of various conifers have been raised for use in planting and for experiments in acclimatization. An experienced forester, whose professional education was had in Switzerland, is in charge of all the technical work, such as supervision of felling, planting and nursery work, conducting of experiments, collecting of data and statistics, and making reports, while the purely business arrangements, such as hiring of labor, purchase and sale of materials, care of property, and the book-keeping and sealing are in charge of a superintendent familiar with such duties. A logging foreman of experience is in charge of the crew and camp, supervising the labor. The College is now in a position to dispose annually of upwards of 15,000 cords of wood for fuel and

the retort, and from 2,000,000 to 4,000,000 feet of logs. The fullest possible utilization of the entire product down to the branchwood, two inches in diameter, has been accomplished, and even the brushwood has been employed to some extent in the production of wood alcohol and in other ways.

That so extensive a series of operations should have been embodied in an actual system of forestry, for which there are no existing models, that a market should have been created and the experiment conducted with good prospect of being self-supporting from the start; that in a country thus far without schools of forestry that could be drawn upon for trained men, and with the practical difficulties attending the importation of foreign specialists, it has been possible to equip and conduct such a school and forest, is sufficient testimony to the ability of the director, who, in the face of extraordinary difficulties, has successfully conducted an undertaking never before attempted, and one of immense importance and promise.

Aside from its value to the State of New York, which has liberally maintained it, the establishment of the school and the College Forest is a matter of great moment to such other States as are immediately concerned with forestry problems and are contemplating necessary legislation. V. M. SPALDING.

Zoological Results based on Material from New Britain, New Guinea, Loyalty Islands and elsewhere, collected during the years 1895, 1896 and 1897, by Arthur Willey. Cambridge, Eng., the University Press. 4to. Part IV. 1900. Pp. viii + 174; pls. 20.

The fourth part of Dr. Willey's 'Zoological Results' contains ten contributions covering a wide range of topics. The first is by J. S. Gardiner and deals with a supposed new species of coral, *Cœnopsammia willeyi*. A very full description of the anatomy of this animal is given and some interesting conclusions concerning its germ layers are drawn. The actinozoa are usually described as covered externally with ectoderm, which at the mouth is reflected inward so as to line the gullet. From the inner end of the gullet the ectoderm is continued as mesenteric filaments over the free edges of the mesenteries. The walls of the gastrovascular cavity are usually said to be lined with entoderm. Gardiner points out that digestion does not take place in the gastrovascular cavity of these animals, but in the so-called gullet whose deep end is imperfectly closed by the mesenteric filaments. The cell lining of the gastrovascular spaces, instead of being concerned with digestion is made up of epithelial muscle cells and of genital cells. These conditions have led Gardiner to redefine the limits of the germ layers in the anthozoa. The layer covering the exterior of the animal is the ectoderm. At the mouth the ectoderm is continuous with the layer lining the gullet and giving rise to the mesenteric filaments. As these are the parts chiefly concerned in digestion, this layer is the entoderm. The lining of the gastrovascular cavity, muscular and reproductive in character, is the mesoderm. Thus the actinozoan is not a diplo-blastic, but a truly triplo-blastic animal.

The paper is well illustrated and the two text figures which show the relations of the calcareous skeleton to the soft parts in *Cœnopsammia* will be welcomed by teachers in general as well as by students of the corals.

The second contribution is a report on the insects of New Britain, by D. Sharp. It consists of notes on some fifteen species of beetles, and on several bees, wasps, and flies. One of the wasps collected, probably *Polistes colonicus*, had the strange habit of laying several eggs in a cell, though in the end only one mature insect emerged from each cell. How the supernumerary larvæ were disposed of and whether this habit was an individual peculiarity or a characteristic of the species were not determined.

Borradaile's account of the crustaceans shows that eighty-two species of stomatopods and macrurans were collected and that twenty of these were new to science.

The slugs were studied by W. E. Collinge, from whose work it appears that six species were found, two of which were new. One of these, *Veronicella willeyi*, is made the basis of a full anatomical study.

According to E. G. Philipps sixty-three species of Polyzoa were collected, of which nine were new. L. R. Thornely notes thirteen species of

hydroids, ten of which have never before been described.

J. J. Lister presents an extended report on a peculiar hard white organism found growing on dead coral in thirty-five fathoms of water. It was made up of a continuous skeleton of solid polyhedral elements penetrated by a system of anastomosing canals; these were lined with soft tissue and were open to the exterior. The soft tissue contained here and there what seemed to be large unsegmented eggs and other masses which had the appearance of parenchymular larvæ. Taking all these peculiarities into account, the author believed the organism to be a sponge, but of so unusual a structure as to justify the erection of a new family for its reception. The species is called *Astrosclera willeyana*, and the family Astroscleridæ.

A series of embryo mound birds and one hatched nestling are reported on by W. P. Pycraft. The feather tracts of the embryo and the nestling plumage are described in detail. The birds are able to fly almost upon hatching, and this has led to the idea that they were at once provided with adult plumage. Pycraft points out that their plumage is not adult, though it is also not true nestling down.

S. J. Hickson and I. L. Hiles report on certain of the octocorallia, two species of Stolonifera and twenty species of Alcyonaria, three of which are new. The Xeniidæ are described by J. H. Ashworth. Of the sixteen known species of soft corals belonging to this genus, Dr. Willey's collection contained representatives of four, as well as material upon which the description of a new species is based.

G. H. Parker.

The Austin [Texas] Dam. By Thomas U. Taylor. Water-Supply and Irrigation papers of the United States Geological Survey, No. 40. Washington, Government Printing Office. 1900. Pp. 52, pl. xvi.

In this publication Professor Taylor, of the Engineering Department of the University of Texas, gives an account of the inception, building, and failure of the 'Austin Dam,' a municipal undertaking for the purpose of controlling the water supply of the Colorado River.

The first foundation stone was laid May 5, 1891, and the disaster, due to an unprecedented flood, occurred April 7, 1900.

As remarked by Mr. F. H. Newell, in his letter of transmittal, "There are many useful lessons to be drawn from the history of such an enterprise, for it often happens that failure is more instructive than success. Throughout the United States many communities are now discussing the utilization of water power for irrigation and other industrial purposes, and they may be saved from mistakes or be led to adopt precautionary measures by a clear understanding of the causes of the disasters which have occurred through the neglect of certain precautions."

The scope of the paper may be seen from the following general headings: Introduction, Preliminary Projects, Construction of Dam, Leak under Head Gate, Flow of Colorado River, Economic Aspect, Silting of Lake McDonald (the body of water back of the dam), Failure of the Dam. The illustrations are both numerous and excellent, some being from photographs taken immediately after the accident.

Among the errors pointed out are the following: That the minimum flow of the river had been greatly overestimated, hence the power developed upon the completion of the dam fell far short of that hoped for; that evaporation as a factor had almost been lost sight of, that the engineers in charge of the work of construction (the dam cost $611,345.29) had been hampered and interfered with in the prosecution of their labors; and that the geologic conditions prevailing at the site had been ignored. To these errors are attributed the failure of the enterprise to meet the expectations of the public and its failure as an engineering feat.

While Professor Taylor's paper is of the greatest interest to the engineering profession, there is much of value in other lines, as, for instance, the carefully conducted investigation of the silting up of Lake McDonald.

Frederic W. Simonds.

February 19, 1901.

SCIENTIFIC JOURNALS AND ARTICLES.

The *American Geologist* for January contains an article by S. E. Bishop on 'Brevity of Tuff

Cone Eruptions.' The discussion is devoted principally to the formation of the cone Leahi, or Diamond Head, in Honolulu, which the author claims, and attempts to prove, was formed by an extremely rapid projection aloft of its material for a few hours, ceasing suddenly and finally. The article is accompanied by a plate. 'Possible new Coal-Plants, etc., in Coal,' Part III., by W. S. Grisley, Erie, Pa. The writer describes and figures about fifty fossils which he thinks may be coal plants hitherto undescribed. Most of the forms described come from a coal bed in Iowa. Mr. John Dresser discussed the 'Petography of Mount Oxford,' a large igneous mass in the Green Mountains of Vermont. The main part of the mountain consists of graywacke, serpentine, ophicalcite and sandstone. A paper follows 'On Some Newly Discovered Areas of Nepheline Syenite in Central Canada,' by Willet G. Miller. In a very interesting paper on 'Peneplains of the Ozark Highlands,' Oscar H. Hershey discusses the life histories of certain parts of the Ozark region. The changes may be briefly put as follows: (1) The entire region was reduced to base level forming cretaceous peneplain. (2) A great dome-shaped uplift occurred in the southern two-thirds of the region, and it was base-leveled again during the Tertiary. (3) A general uplift throughout the Ozarks, which was again eroded and base-leveled in some places during the Pliocene. (4) Another general uplift, greatest in southern Missouri. (5) A local uplift of the Boston Mountains during the modern epoch. Following are the 'Reviews of Recent Geological Literature' and 'Personal and Scientific News.'

IN *Popular Astronomy* for April Herbert A. Howe continues his discussion of astronomical books for the use of students, taking up general popular works, descriptive text-books and hand-books. Professor Harold Jacoby, of the Astronomical Observatory of Columbia University, writes under the title of 'The Astronomer's Pole,' of the work to be done at the new Helsingfors Observatory. Illustrations of the instruments and building accompany the article. Anderson's 'New Star in Perseus' is the subject of several articles, and notes. Circular No. 56, from the Harvard Observatory, by E. C. Pickering, with reference to the Nova is printed in full; the first chart and catalogue for observing it is given by J. G. Hagen, S.J., of the Georgetown College Observatory, Washington, and Dr. H. C. Wilson, of Goodsell Observatory, adds much to the general information of the Nova, and includes a chart of its light curve. Shorter articles are by R. W. McFarland, on 'Ancient Eclipses and Chronology'; by Dr. George Bruce Halsted on 'Astral Geometry,' and by A. E. Douglass, on 'Photographs of the Zodiacal Light'; the latter is accompanied by an excellent plate. Eclipse cyclones are discussed, and there is a translation of H. Arctowski's article on 'Northern and Southern Lights illuminating the Heavens at the Same Time,' which recently appeared in *Ciel et Terre*. Planet, spectroscopic, comet and asteroid notes occupy the usual space. Among the 'General Notes' are the following: Board of Visitors at the Naval Observatory, Trouble at the Naval Observatory, Naval Observatory Legislation, Observations of Nova Persei at Seagrave Observatory, At Yerkes Observatory, At Ladd Observatory, At Vassar College Observatory, At Pomona College, Notation of New Variables, Nomenclature of Variable Stars, Crocker Eclipse Expedition to Sumatra, Spectrum of ζ Puppis, Evanescent Star Photographs.

IN Italy has just appeared a new mathematical journal, issued at Città di Castello, by the publisher, S. Lapi, to whom the annual subscription, 12 francs, should be sent. It is a monthly magazine, called *Le Matematiche*, under the direction of Professor C. Alasia, with a board of collaborators, among whom the English language is represented by G. B. Halsted, of Austin, Texas, to whom communications may be sent, which will appear in Italian. On the editorial board may also be noted the Russian, Vasiliev, and the greatest of living mathematicians, Poincaré. The first number, February, 1901, contains the last thing written for publication by the illustrious Hermite, dated January, 1901, on the 14th of which month he died. The magazine has a suggestive new department, headed 'Subjects for Research.'

WE have received with pleasure the first number of *School Science*, a monthly journal

devoted to the teaching of science in secondary schools, edited by C. E. Linebarger and published at Chicago, Ill. There are twelve associate editors, all teachers in secondary schools, and the contributions given in the first number and promised are chiefly from teachers in secondary schools, though the present number contains contributions from Professor Palmer, of the University of Colorado, and Professor Nichols, of Cornell University. The journal is evidently edited with care, and will exert an excellent influence.

SOCIETIES AND ACADEMIES.

ANTHROPOLOGICAL SOCIETY OF WASHINGTON.

THE 314th meeting of the Anthropological Society was held on March 12th.

Dr. J. Walter Fewkes presented some historical documents, consisting of a fac-simile of the map of Padre Menchero (1747) of the territory now embraced in Arizona and New Mexico; a fac-simile of the map of Juan de la Cosa (1500), showing the famous demarcation line of Pope Alexander II. and the discoveries in the New World at that period, and an unpublished manuscript of Antonio Alzate, describing the ruins of Xochicalco, Mexico. The Menchero map, which is rare and little known, gives the locations of the missions in the Southwest, and valuable ethnological data. It was issued at Berlin. The Cosa map was copied during the Columbian Historical Exposition at Madrid in 1892-3 from the original lent by the Vatican. Dr. Fewkes pointed out that Alzate was the first to call attention to the need for preserving the ruins in Mexico.

President W. H. Holmes presented instruments of execution and torture, exhibiting an iron cage found some years ago by workmen engaged in road building in King George County, Virginia. This cage is constructed roughly on the outlines of a human body, and on discovery contained a human skeleton, most of which is still preserved. Mr. Holmes said that no documentary evidence has yet been found of 'hanging in chains' in the United States. He called attention to a similar gibbet found in Jamaica and stated that this form of post-mortem exposure of the bodies of criminals is English, and was practised as long ago as the twelfth century. The last gibbet was constructed and used in England in 1832. There is no very reliable record of the hanging of living persons in these cages, although tradition has it that such was the practise. At the close of his remarks Mr. Holmes exhibited a large collection of instruments of torture brought to this country from Hanover, Germany, by Anton Heitmuller, of Washington.

The first paper of the evening was entitled 'Ethnology in the Jesuit Relations,' by Mr. Joseph D. McGuire. Mr. McGuire has carefully gone over the collection of Relations, recently published under the editorship of Reuben Goldthwaites, extracting all ethnologic and archeologic data. This paper is the first of a series having in view the rehabilitation of the American Indian at the period of first contact with the white man, as far as can be done by examination of the literature. Mr. McGuire's paper was listened to with much interest.

Mr. W J McGee's paper on the 'Cocopa Indians' occupied the remainder of the session. Mr. McGee went into considerable detail as to the arts and customs of the Cocopas, whom he visited last summer. The custom of burning the house of the deceased, and the communistic division of the property among the friends, exclusive of the relations, in the event of a death, coupled with the periodical removals from the flood-plain of the Colorado to higher ground, and *vice versa*, have exerted a profound repressive influence on the Cocopas. These Indians were found to be at a low ebb numerically and physically, and are without doubt rapidly tending to extinction.

WALTER HOUGH.

THE SCIENCE CLUB OF UPPER IOWA UNIVERSITY.

THE last regular meeting of the Club was held February 27th. Arthur E. Bennett described his researches among the prehistoric remains of New Mexico, including skeletons, utensils, pursuits, pottery, decorations, worship, etc. He stated that the plain, mesa and cliff dwellers were really one people. At the next meeting he proposed to discuss the prob-

able cause of extermination of these people. He has spent four summers on the ground.

A second paper, read by Bruce Fink, was an ecologic study of the swamp vegetation of northern Minnesota. *Marchantia*, *Sphagnum*, the conifers, the heaths and the orchids were especially considered. No less than thirteen species of orchids collected in these swamps were exhibited, and it was incidentally stated that fourteen species have been collected within ten miles of the University at Fayette, Iowa.

SCIENCE CLUB OF THE UNIVERSITY OF WISCONSIN.

THE regular monthly meeting of the club was held on March 1st, at 7:30 P. M., President E. A. Birge presiding. The program of the evening consisted of an address by Professor Ira Remsen, of Johns Hopkins University, on the subject, 'The Outlook in Chemistry.' The speaker emphasized the importance of the researches of such men as Cavendish, Scheele, Priestley, Lavoisier, Berzelius, Liebig and Wöhler. He characterized the work of Lavoisier as revolutionary, and stated that since his time such revolutions have not marked the progress of chemistry. The advance of chemistry, and of other sciences as well, was spoken of as taking place in waves. After the important, fundamental work at the close of the eighteenth and the beginning of the nineteenth century came the activity in organic chemistry, while at present a large amount of energy is directed to physical chemistry in particular. After mentioning some of the triumphs of synthetic work in organic chemistry, Professor Remsen expressed the opinion that a long time would still have to elapse before all the various products of organic beings could be prepared in the laboratory. An audience of about five hundred persons listened to the lecture, which abounded in food for thought interspersed with appropriate anecdotes and witticisms.

LOUIS KAHLENBERG.

THE ELISHA MITCHELL SCIENTIFIC SOCIETY.

AT the 133d meeting of the Society, on March 12th, in the Chemical Lecture Room of the University of North Carolina, the following papers were read:

'A Marsupial Track in the Triassic,' Professor Collier Cobb (by title).

'A New and True Antidote for Carbolic Acid,' Professor E. V. Howell.

'Yellow Fever and Mosquitoes,' Professor R. H. Whitehead.

'The World's Production of Iron and Steel,' Professor Chas. Baskerville.

CHAS. BASKERVILLE,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE DATE OF RAFINESQUE'S DEATH.

EDITOR OF SCIENCE: In looking over some back numbers of SCIENCE quite a year old, I have happened upon the interesting letters between Rafinesque and Professor Wagner as given by Mr. T. L. Montgomery in SCIENCE for March 23, 1900. I do not know how I came to miss this item of so long ago, else this note would have been sent you in earlier reply.

The date of Rafinesque's death is correctly given by me in my 'Life and Writings of Rafinesque' as September 18, 1840. I am aware and at the time was aware of the date September 18, 1842, as cited by Mr. Montgomery. I also am aware that all the dates he cites from the various authorities he names are incorrect and all started from the same original error. Evidently an overlooked typographical error in the original publication was the cause.

If Mr. Montgomery had looked carefully at the certified copy of Rafinesque's will, which forms the end of my volume, he would have noted that on November 16, 1840, the signature was attested as being that of Rafinesque by two persons, James Henry Horn and Sam Hood; that on November 28, 1840, James Mease, as executor, was duly sworn for that office and each of the above facts dated in November, 1840. Of course it is hardly necessary to say that wills are not probated two years before a man dies.

The date 1842 is often found in biographical notices of Rafinesque, but all seem to originate in the error of the first notice. I have always imagined that date to be a typographical error. My authority for 1840, as the year, is the will

of Rafinesque probated in November of that year.

R. ELLSWORTH CALL.

BROOKLYN, N. Y., March 14, 1901.

LUNAR HALO.

TO THE EDITOR OF SCIENCE: On February 25, 1901, there was visible in this locality a lunar halo of rather peculiar form. After vain attempts to find an explanation of it the writer asks the privilege of an appeal to the readers of SCIENCE. This phenomenon consisted of an elliptical ring around the moon with axes apparently about six degrees and nine degrees respectively. The principal axis of the ellipse was vertical while the terminator of light on the moon's surface made an angle of about 45 degrees with the horizon. The moon was about half way down in the southwest and half full. A southeast breeze was blowing and very thin fleecy clouds could be seen passing over the face of the moon. The ring persisted for fifteen minutes or more.

The peculiar orientation of the terminator and major axis is the difficult part to explain. One might expect an elliptical though perhaps ill-defined ring from an elongated source of light, but why should the major axis be inclined to the terminator?

C. M. BROOMALL.

MEDIA, PA., March 23, 1901.

SHORTER ARTICLES.

THE LARGEST KNOWN DINOSAUR.

THE Field Columbian Museum paleontological expedition of the past summer was fortunate in securing a number of Dinosaur bones belonging to an animal unique both in size and in proportions. These bones consist of a femur, a humerus, a coracoid, the sacrum, an ilium, a series of seven presacral vertebræ, two caudal vertebræ, and a number of ribs. Part of this collection has been placed on exhibition and the remainder will follow from time to time as the work of preparation proceeds.

The most striking characteristic of this animal, so far developed, is the relative length of the front and hind legs. While the humerus of *Brontosaurus excelsus* Marsh is a little more than two-thirds as long as the femur, the humerus of the individual in question is decidedly the longer bone of the two.

The femur is a stout bone with expanded condyles and a head not constricted from the shaft. The specimen is somewhat crushed antero-posteriorly, but otherwise in a fine state of preservation. Its greatest length parallel to the axis of the shaft is 80 inches (2,003 m.), which is six inches longer than the femur of Marsh's *Atlantosaurus*. The humerus is broad at the proximal end, but unusually slender in the shaft. It has suffered somewhat from weathering, so that the entire surface of the distal end has flaked away, leaving a firm chalcedony core. In this condition its length is equal to that of the femur; with the articular end complete it would probably exceed it by two or more inches. Its present length is greater by 23 inches than the longest humerus hitherto known to science.

The coracoid is broad and straight at the scapular articulation, but less massive than that of *Brontosaurus*. The sacrum is made up of four coossified vertebræ, having small lateral cavities in the centra. A complete rib, presumably from about the sixth presacral vertebræ, measures more than nine feet in length. Some of the thoracic ribs have a secondary tubercle, and also a foramen leading to a cavity in the shaft. However, these may not prove to be constant characteristics.

The similarity of the femur to that of *Atlantosaurus*, together with the presence of but four vertebræ in the sacrum, suggests that this animal may belong to that group. The writer does not feel justified in creating a new genus until the material shall have been sufficiently worked out to make an accurate determination possible. However, the evidence at hand is sufficent to show that we have here to do with an animal which differs radically from any well-known Dinosaur. The extraordinary length of the humerus, together with the size of the coracoid, suggests an animal whose shoulders would rise high above the pelvic region, giving the body something of a giraffe-like proportion. The relatively smaller size of the anterior caudal vertebræ indicates a lesser development of the tail than is common among the sauropod

Dinosaurs. Along with these proportions we may well expect to find a correspondingly shorter neck and perhaps an animal fitted for arboreal food habits. Such a short-necked type was long since suggested by Marsh in his *Apatosaurus laticollis*.*

In a future publication of the Field Columbian Museum a complete description of this most interesting Dinosaur will be given.

ELMER S. RIGGS.

FIELD COLUMBIAN MUSEUM,
March 16, 1901.

A RECENT FAULT-SLIP, OGDEN CANYON, UTAH.

IT is generally known that the western face of the Wasatch range, Utah, is determined by a profound fault, and that numerous minor faults are observable at the base of the range. At the mouth of Ogden canyon these secondary faults are particularly plain. Recently there occurred at the locality named a very slight slip along one of the minor fault planes. The movement opened a crack in a mass of gneiss through which a tunnel has been cut as a part of the conduit pertaining to the Ogden Power and Light Company's generating plant. The tunnel walls were fractured, a crack averaging one and a half inches appearing on the inside. The escaping water found outlets on the mountain side at depths of from fifty to a hundred and fifty feet below the tunnel floor, and in its course it carried down many tons of boulders and debris. A steel bridge over the Ogden river was completely destroyed. The disturbance was strictly local, and apparently was due to the escape of water from the tunnel down the plane of faulting, thus constituting a column which by hydrostatic pressure further shifted the block. As to expansion through freezing being the probable cause, there is none but negative evidence. Repairs are in progress. These consist in the removal of the upper part of the shifted block, and in carrying a wooden pipe line through the tunnel.

It appears that the water was first seen issuing from the side of the mountain below the tunnel within a few days after the occurrence of a slight earth-tremor in the vicinity. In the loose alluvial deposits along the mountain front on the north of the canyon mouth, cracks and subsequent settlings have appeared.

QUOTATIONS.

THE U. S. NAVAL OBSERVATORY.

THE Secretary of the Navy has temporarily ended the Naval Observatory troubles, without the aid of a court of inquiry or court-martial, by detaching Professor Stimson J. Brown from the institution. * * * It would seem from this that Secretary Long shares with Capt. Davis, the superintendent of the Observatory, the belief that Professor Brown transgressed the naval regulations in his efforts to have Congress pass the legislation needed to make the institution a great national one, and not a mere adjunct to the navy. As Capt. Davis's tour of shore duty expires before long, a new superintendent may be looked for within six months, and peace in the Observatory may be expected until the new superintendent and new director of astronomy come to a parting of the ways. Meanwhile, scientists all over the country are being urged to come to the rescue of the Observatory by bringing pressure to bear upon Congress. A bill which met the approval of SCIENCE was introduced in the Senate in the last session by Senator Morgan. It provided for the nationalization of the Observatory and for the appointment as director of an eminent astronomer, 'to be selected from the astronomers of the National Academy of Sciences, unless in the judgment of the President one of higher scientific and executive qualifications be found.' Friends of the institution should see to it that a similar bill is introduced at the opening of the next Congress and vigorously pushed to passage.—The N. Y. *Evening Post.*

POLITICS AND STATE UNIVERSITIES.

To form a just conception of the working of the State university, we should go to the older States of the Central West, where State universities have long been in existence, and where they have had time to shape, in a measure at least, public opinion on university education. In this part of the country the four most conspicuous and liberally supported State universities are those of Michigan, Illinois, Wisconsin

and Minnesota. In these States the tenure of the university president compares very favorably with that of any other class of educational institutions in any part of the country. Among the conspicuous college presidents of the United States, President Angell stands next in seniority to President Eliot, of Harvard. The presidents of these four State universities have served terms varying from seven to thirty years, and averaging over fifteen years. The significance of this long tenure of office is apparent, if we recall the uncertain and fluctuating fortunes of the two great political parties in these Northwestern States during the last ten years.

A particularly striking instance of the development of public opinion against political interference may be found in Illinois. In the year 1894 the State University was subject to the management of a Board of Trustees, consisting of nine elective and three *ex-officio* members. Of the nine elective members of the Board, six were Democrats, as were also at least two of the three *ex-officio* members. One of these two, a member in fact as well as in name, was Governor John P. Altgeld, the vigor of whose partisanship no one will question. In spite of this decisive Democratic majority in the Board of Trustees, that body elected as the new president of the University a gentleman who was well known as a member of the opposite political party, and who had held, a few years before, a conspicuous and responsible position in the party councils of another State. * * *

The freedom of university teaching will probably always stand in need of jealous defenders. No human institution can secure itself absolutely against all influences in restraint of truth, some of which are none the less serious because they are not of a kind to attract public attention. Yet, all things considered, the State universities of the Central West may fairly claim to have made a good stand for non-partisan treatment of university teaching.—*The Independent*, N. Y.

CURRENT NOTES ON PHYSIOGRAPHY.

SNAKE RIVER CANYON.

SOME brief account of the great canyon of Snake river is presented by W. Lindgren (The gold and silver veins of Silver city, de Lamar and other mining districts in Idaho, '20th Annual Report, U. S. Geological Survey,' 1900, pt. 3, 65–256, numerous plates and figures), supplementing the description given a few years ago by Russell (U. S. Geological Survey, Water-Supply and Irrigation Paper, No. 4, 1897). Where the river forms the western boundary of Idaho, the lava plateau has an elevation of from 6,000 to 7,000 feet; its successive flows, revealed in the dark brown canyon walls, are from 20 to 150 feet thick. Hereabouts, the river has cut down into the pre-lava mountains, the contact revealing a buried surface of strong relief. The canyon walls for a depth of 2,500 feet are benched on the horizontal lava beds; a remaining depth of the same amount is steeply buttressed with porphyries and diorites. "The bottom of the old valleys clearly lie far below the deep cut of Snake river, how far is not known. * * * It may be confidently advanced as a working hypothesis that this whole district * * * far from having been elevated since the Tertiary era * * * represents an area of depression, standing now at lower levels than during the Miocene period" (93).

ALPINE MORPHOLOGY.

A MONOGRAPH of unusual interest and value is found in E. Richter's 'Geomorphologische Untersuchungen in den Hochalpen' (*Pet. Mitt.*, Erg'heft 132, 1900, 103 p., 6 pl., 14 fig.).

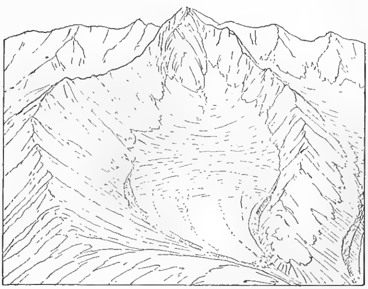

FIG. 1.—A corry beneath a sharp peak with serrate spurs.

It is concerned particularly with the origin of Kahre (cirques, corries, botner), which consti-

tute so characteristic a feature of the high Alps: arm-chair-like recesses in the mountain slope, frequently arranged in groups all backing towards a central peak or an axial ridge and separated by sharply serrate spurs. Valley troughs are also considered, and these as well as the Kahre are referred to glacial erosion under conditions that are critically specified. Among many important conclusions are the following: The high Alps, rising above the snow-line of the glacial period, owe their form largely to the destructive processes of that time. Whole ranges, 100 kilometers long, exhibit sharp high-mountain forms, with corries and serrate spurs, although they bear no glaciers at present. If it had not been for the glacial period, these ranges would to-day have the rounded forms appropriate to mountains of middle height. During the most extensive glaciation, the Swiss ice-fields stood so high—even over the forelands towards the Jura—that they were above the level of the snow-line; the slope of the snowy surface was gentle and the movement of the ice-streams in the larger valleys must have been slow. The trough form that obtains in all the strongly glaciated valleys—with over-deepened floors and over-steepened walls—is due to erosion by glaciers of medium size, whose surface did not rise above the trough walls, but whose movement must have been relatively rapid because their surface slope was strong. Ice-scouring during maximum glaciation reached far up the mountain slopes above the trough walls, but was without great influence on form. A level of extensive erosion is seen in the high Alps, coincident with the snow line of the glacial period; the peaks that rose above this level were actively consumed by weathering, while the surrounding valleys were smothered in heavy but slow-moving ice.

NEW ZEALAND.

THE ninth volume of the *Bibliothek der Länderkunde*, entitled 'Neuseeland' by R. von Lendenfeld (Berlin, Schall, 1900, 186 p., 24 pl. and fig., map), is a very attractive volume from which one may gain a clear impression of the country dealt with. Limiting this note to sections of a physiographic nature, mention may be made of Banks peninsula, a dissected volcanic group, standing in front of the Canterbury plains, with which it is connected by long tangential sand reefs. A tunnel cut through one of the volcanic slopes has disclosed 174 different layers; lava, loose or compact, conglomerate, and weathered soil. The Canterbury plains, composed of recent fluviatile deposits brought from the mountainous background, have a gentle slope seawards; the flooded rivers build up their surface with coarser deposits near the mountains and finer deposits near the shore; as their channels become clogged, the water deserts them for new courses, thus the whole surface is slowly aggrading. The account of the fiords of the southwest coast mentions their numerous waterfalls, but one must read between the lines to see that the falls leap forward from hanging valleys, such as now appear to be characteristic of strongly glaciated mountains. A striking example of such a valley seems to be shown in the plate of Mitre peak, Milford sound (fiord). The volume has a good index, but the pages are headed only with their numbers, in German fashion. The frontispiece of Mount Tasman and the Hochstetter glacier is remarkably fine.

W. M. DAVIS.

CONTEMPORARY THERMODYNAMIC EFFICIENCIES.

THIS is the day of remarkable things in the field of heat-engine construction. The *Inchdune*, and a sister ship on the 'Inch Line' of a well-known British steamship company, has produced the horse-power-hour on 0.96 pound of coal and, for the time, holds the world's record in steam-engine efficiency. This gives an efficiency, between the coal-pile and the point of transformation into power of the potential energy of the fuel, of almost precisely twenty per cent.

The steam-turbine is produced in such perfection of design and construction as to compete with the best of reciprocating engines of similar power and the report now appears in the German engineers' *Zeitschrift* that Jacobson, at Potschmühle, has tested a Laval Turbine which, rated at 300 horse-power, demands

but 7 kilograms per horse-power-hour at its rating, a trifle more at 342 delivered horse-power, and, a most remarkable achievement, at one-tenth its rated power only increases the consumption of steam to 9.74 kgs. This is better than any record yet reported for the reciprocating engine in maintenance of efficiency with diminishing delivery. The steam-pressure was about 8.5 atmospheres. Superheating gave about ten per cent. gain. The speed of the machine was about 10,000 revolutions a minute. A condenser was employed.

The Engineer-in-Chief of the U. S. Navy, Admiral Melville, reports in his annual message to the Department a remarkable set of data from the trial of the water-tube boilers of the U. S. S. *Cincinnati.* Steam was raised from cold water to a pressure of 215 pounds in 12 minutes, 40 seconds and without injury. The old shell-boiler would have needed several hours for getting up steam and, if forced, would have been expected to develop leaky tubes in all directions. After steam was up, the series of trials reported on was made, with forced draught, fuel being burned at rates ranging between 20 pounds, as a minimum, to above 50 pounds, per square foot of grate area, and with resulting evaporation of water of from nine pounds per pound of fuel, at the minimum, to 8.6 at the maximum rate of combustion. This is the equivalent of from 12.19 to 11.43, 'from and at' 212° F., per pound of combustible portion of the fuel, an efficiency of boiler of from 85 to 90 per cent. The coal used was of the Pocahontas variety, which contains ordinarily but two or three per cent. of ash. Here the ash and refuse in unburned coal and clinker amounted to about ten per cent. This is the most remarkable performance of which we have record. The evaporation is excellent at the lowest rate of combustion and wonderfully well sustained through the higher ranges. It probably constitutes a world's record to date.

Gas and oil and petroleum-vapor engines are also coming to the fore in a remarkable way and the beginning of the twentieth century already commences to show the quality of the new era in these directions Mr. H. A. Marshall has recently presented a paper to the British Institution of Mechanical Engineers, now just published, in which he gives the outcome of investigations of the efficiencies of the gas-engines employing 'power-gas' of the Mond variety, differing from the well-known Dowson gas in the fact that it is made from bituminous 'slack,' instead of from anthracite. It requires the use of enormous quantities of steam—250 per cent. of the weight of the fuel—and makes a very lean gas; but it employs so cheap a grade of fuel as to furnish the unit of heat at an unprecedentedly low cost. It makes 150,000 cubic feet of gas per *ton* and this yields 2,000 horse-power-hours in large gas-engines of good construction. A by-product, ammonium sulphate, more than recoups the original cost of the fuel, with the English coals used. The outcome of this improvement and of the adoption of the gas-engine in large sizes for extensive work is that, whereas the cost of fuel for the ideal steam-engine of modern practice should not exceed about a half-cent, the real engine demands, as a minimum, one cent, and the average engine of the large British stations one and a half-cent, or more; while the gas-engine has come down to a considerably lower cost than the minimum just given. The figures for heat-units demanded are reported as about 25,000 B. T. U. per horse-power-hour for the best steam-engine and but 11,500 for the gas-engine, under best conditions and continuously working. The real comparison is necessarily that of costs of production of the unit of power and it is this relation which will ultimately determine the supremacy of one of the competing heat-engines.

Gas-engines are now built in large powers—1,500 H. P., and larger powers can be readily supplied if called for—and are found to involve less practical difficulty on the large than on the small scale. They are now durable, regulate well and are economical in use of exceedingly cheap fuels. The results obtained at Winnington, as reported by Marshall, are, in fact, not only better, thermodynamically, than those given by any existing steam-engine, but are even better than even the ideals of the case brought into the comparison; all of which are engines in use in English power and lighting

stations. The actual weight of fuel used at Winnington is one pound per h.-p.-h. This is substantially the same as the figure for the record-breaking steam-engine in marine practice already referred to; but the latter uses the most costly, the gas-engine the least expensive, fuel, and this is the vital matter. The gas-engine now has attained a mechanical efficiency of about 85 per cent. and a thermal efficiency exceeding 25 per cent.; both figures representing the practical limit in steam-engine practice also, although the former is sometimes exceeded. In both engines the efficiency, on the basis of the brake horse-power, is about twenty per cent., occasionally one or two units higher.

The Mond gas, with a thermal content of 150 *B.T.U.* per cubic foot, sells for twopence per thousand; this can be compared with our own illuminating and natural gases, storing 600 and 1,000 *B. T. U.*; of which, respectively, 16 and 9 cubic feet are used in good gas-engines, per horse-power-hour, while of the Mond gas at least 75 cubic feet are demanded.

Summing up the case: It may be said that the best work of the large gas-engine gives a thermal efficiency substantially the same as that of the very best steam-engine while it employs a fuel which is considerably cheaper than is employed where this comparison is, as here, made on the basis of fuel consumed. Its 'cost of plant,' on a large scale, is now quite as low.

The balance sheet of the best single gas-engine reported stands thus:

	Heat transformed, *B. T. U.*	33.65
Heat received	Heat lost	
from	Cylinder-jacket.........	19.28
the fuel	Piston.....................	4.94
B. T. U.	Exhaust valve...........	3.34
100.	Total in cooling water...	27.00
	Heat waste in exhaust, etc.	38.79
		100.00

This is superior to any steam-engine performance yet reported.

During the discussion, Mr. Donkin reported in tabular form the best results of tests of gas-engines made in the United States with natural gas, the richest gas-fuel, either natural or artificial, available for large engines. The best figures in the table are those obtained in a Sibley College test of a Westinghouse gas-engine and reported by Messrs. Millar and Gladden in the *Sibley Journal* of June, 1900. The power developed was, net, 606 *H. P.*, the mechanical efficiency of the machine 90 per cent., the heating value of the gas about 1,000 *B. T. U.* per cubic foot, the consumption ranging from 10 cubic feet per *B. H. P.* to 8.8 for the indicated power. This gives a thermal efficiency of 25.5 per cent. The same figure is obtained, according to Mr. Donkin's tables, in Mr. Humphrey's test of an engine of a similar power of English make using Mond gas.

The twentieth century opens with the gas-engine for the first time in its century of evolution seriously competing with the steam-engine in important commercial work on a large scale.

R. H. THURSTON.

THE U. S. GEOLOGICAL SURVEY.

FOR the support of the U. S. Geologial Survey for the fiscal year ending June 30, 1902, Congress appropriated at the session just closed about $1,018,000, an increase of $52,000 or more over the present year's appropriation. Indeed, there was a strong disposition in Congress to make a material increase, notably for the extension of hydrographic investigations.

Of the several sums appropriated $250,000 is for the topographic surveys, including a report on the topography and geology of the territory adjacent to the 49th Parallel, west of the 110th Meridian. For the survey of the forest reserves there is $130,000, the same as the present year. For geologic surveys the amount is $150,000—no increase—and for the continuation of the investigation of the mineral resources of Alaska, $60,000. For paleontologic researches there is $10,000. For chemical and physical researches relating to the geology of the United States there is granted $20,000, being $10,000 more than the sum appropriated for the present year. The increase will enable the Director to carry on needful and long neglected physical researches in connection with the chemical work of the Survey. For want of funds the Survey has had no physical laboratory for some years.

For the collection of data and the preparation of a report on the mineral resources of the

United States there will be $50,000, the same as for the present year, but an increase as compared with former years.

The appropriation for gauging streams and determining the water supply of the United States, including the investigation of underground currents in arid and semi-arid sections is likewise the same as this year—$100,000.

With a view to meeting as far as possible a very strong demand from the people for an extension of the hydrographic work of the Survey, there was practical unanimity in Congress in favor of a large increase in the allowance for this work. The increase was provided for in the form of an amendment to the River and Harbor Bill, and hence, like many other items covering meritorious objects, it went down to defeat in the last hour of the session with that now famous measure.

Other items under the appropriation are for engraving and printing, preparation of illustrations, rent of quarters, etc. There is $12,000 for furniture for a new addition to the Survey building in Washington.

Congress also granted upwards of $15,000 to cover deficiencies for the current year.

SCIENTIFIC NOTES AND NEWS.

DR. CHARLES F. CHANDLER, professor of chemistry in Columbia University, has been appointed by the President a member of the Board of Visitors of the U. S. Naval Observatory, in the place of Mr. Clair McKelway, of Brooklyn, who did not accept the position.

THREE expert geologists from the U. S. Geological Survey have been detailed to make a geologic and mineral reconnaissance of the Island of Cuba. They are Dr. C. Willard Hayes, Mr. T. Wayland Vaughan and Mr. A. C. Spencer. Mr. Spencer has not yet started from Washington, but Messrs. Hayes and Vaughan have already reached the island and taken up their work, after conference with the military governor. It is expected that these geologists will accomplish results of distinct economic value to the island. The assignment of these United States geologists to work in Cuba is made at the request of Major-General Wood, the military governor, and of Secretary of War Root, and is with the approval of Secretary of the Interior Hitchcock. The expenses will be met by the Cuban Government.

PROFESSOR S. M. BABCOCK of the University of Wisconsin, inventor of the Babcock milk test, was, on March 27th, presented with a medal, voted him by the State for giving his inventions free to the world. Exercises were held in the Assembly Chamber of the Capitol in the presence of both Houses of the Legislature, the university faculty, Supreme Court, university regents and many prominent citizens of the State. Governor Lafollete presided and addresses were made by him, by ex-Governor W. D. Hoard and others.

AN influential committee has been formed in Italy to celebrate the fortieth anniversary of Professor Paul Mantegazza's entrance on his career as a teacher. This event will be celebrated at Florence on April 30th, and at the same time the thirtieth anniversary of the Italian Society of Anthropology. It is proposed to collect a sum of money to be used for the endowment of the new laboratory of anthropometry which Professor Mantegazza has established at Florence.

THE University of Aberdeen is about to confer the honorary degree of LL.D. on Professor Virchow, of Berlin, and on Major Alfred W. Alcock, superintendent of the Indian Museum, Calcutta, and professor of zoology in the Medical College of that city.

PROFESSOR C. LLOYD MORGAN gave the Croonian Lecture before the Royal Society on March 21st, the subject being 'Studies in Visual Sensation.'

DR. RICHARD R. WETTSTEIN VON WETTERSHEIM, professor of botany at the University of Vienna, has been elected president of the Zoological and Botanical Society of Vienna.

M. HUMBERT has been elected a member of the section of geometry of the Paris Academy of Sciences to fill the vacancy caused by the death of M. Hermite, and M. Normand has been elected a correspondent in the section of geography and navigation in the room of the late General de Tillo.

THE Medical Club of Philadelphia gave a re-

ception on March 29th, at the Bellevue Hotel, in honor of Dr. Charles L. Dana.

THE freedom of the Leathersellers' Company was conferred, on March 15th, on Sir William MacCormac, in recognition of his distinguished services to medical science.

WILLIAM HARPER, who for some years has been the chief of the statistical bureau of the Philadelphia Commercial Museums, has resigned to undertake similar work in London.

WE regret to learn that Dr. Horatio C. Wood, professor of therapeutics in the University of Pennsylvania, and eminent for his contributions to therapeutical and botanical subjects, has been compelled by ill health to give up temporarily his lectures and other work.

THE decoration of the Mérite Agricole has been conferred by the French Government upon the following officers of the Department of Agriculture for services in connection with the Paris Exposition: Dr. H. W. Wiley, chief chemist; Major H. E. Alvord, chief of the dairy division; Col. G. B. Brackett, pomologist; W. A. Taylor, assistant pomologist; M. A. Carleton, cerealist; and John I. Schulte, one of the associatee ditors of the *Experiment Station Record*. The decoration also has been conferred upon James L. Farmer, assistant director of agriculture for the Paris Exposition.

THE Smith's prizes of Cambridge University have been adjudged to Godfrey Harold Hardy, B.A., 4th Wrangler, 1898, scholar of Trinity College, for his essay on 'Definite Integrals of Discontinuous Functions,' and to James Hopwood Jeans, B.A., scholar of Trinity College, bracketed 2d Wrangler, 1898, for his essay on 'The Distribution of Molecular Energy.'

A MARBLE tablet in memory of the eminent French chemist, J. B. Dumas, who died in 1884, has been placed in the house in the rue St. Dominique, Paris, where he formerly lived.

A MEMORIAL marble bust of Robert Brown, the eminent botanist, formerly a student at University of Aberdeen, presented to the University by Miss Hope Paton, has been unveiled in the picture gallery of Marischal College.

THE death is announced of M. Montard, an eminent French mathematician and engineer; of Baron Keiské Ito, professor of botany at the University of Tokyo, who died on January 21st, at the age of ninety-nine years, and of Dr. Peter M. Pokrowski, professor of mathematics at Kiew, on March 3d, at the age of forty-four years.

THE second Latin-American Scientific Congress opened its two weeks session at Montevideo on March 20th, with over 200 delegates in attendance. Dr. Robert Wernicke, professor of pathology in the University of Buenos Aires, Argentine Republic, was elected president of the Congress.

WE learn from the *British Medical Journal* that Professor Robert Koch is staying at Rovigno, on the Adriatic, where he is inspecting the Marine Zoological German Institute, to which he hopes to affiliate a malaria institute for the Istrian district. Koch's late stay in New Guinea has been fruitful in good results, the fight against malaria having been continued energetically on the lines laid down by him. Unfortunately the disease is very prevalent in the German colonies of East Africa. A medical officer with assistants and the necessary scientific apparatus is to be sent out there by the German Government, for which purpose 30,000 Marks have been voted by the Reichstag.

THE Coast and Geodetic Survey steamships *Pathfinder* and *McArthur*, at San Francisco, and the *Patterson* and *Gedney*, at Seattle, are now fitting up under orders to proceed to Alaska to survey important passages among the islands along the Alaskan coast. The existing charts are based on old Russian ones, corrected from time to time by reconnaissance surveys.

THE Convocation of Oxford University has rejected by a vote of 126 to 125 a resolution to build a house in the Parks adjacent to the observatory as a residence for the professor of astronomy.

SECRETARY WILSON has arranged to carry into effect, on July 1st, the reorganization of certain of the divisions of the Department of Agriculture, as provided by the last Congress. It will be remembered that, in addition to the Weather Bureau and the Bureau of Animal Industry, four new bureaus were created—of Plant Industry, of Forestry, of Chemistry and of Soils.

NEWS has been received from the eclipse expedition sent out by the Massachusetts Institute of Technology to observe the total eclipse of the sun at Sumatra. Professor Burton and his assistants took the Dutch steamship *Konigin Regentes* at Genoa on March 12, and found on this steamer an official expedition sent out by the Netherlands Government. All the instruments were safely placed on board the steamer, which goes directly to Padang.

THE ground occupied by the building of the U. S. Fish Commission, at Washington, has been granted to the Baltimore and Potomac Railroad, and the building will be removed to another part of the Mall, west of its present position. The railway company must pay $40,000 towards the cost of rebuilding.

IT has been announced that Mr. J. P. Morgan was the donor not only of the Tiffany collection of gems and pearls, but also of the Bement collection of minerals and meteorites to the American Museum of Natural History.

THE Department of Zoology and Entomology of the Ohio State University has secured a very interesting and valuable collection of Ohio birds through the generosity of Mr. W. L. Hayden, of Columbus. It includes representatives of a large number of native birds and is noteworthy from the fact that the different species are shown with their natural surroundings, nests, eggs and often young, as well as old, birds of both sexes. Some particularly striking effects are produced with the nests of owls and woodpeckers included in sections of the trees in which they were constructed. The collection is arranged in forty-two handsome cases, finished in oak, and is stated to have cost over one thousand dollars in its preparation, not counting the time, ingenuity and skill which Mr. Hayden has lavished upon it.

THE father and uncle of Dr. Walter Myers, whose life was sacrificed in the study of yellow fever, have given £1,500 to the Liverpool School of Tropical Medicine for the prosecution of its investigations.

PROFESSER WILLIAM OSLER of Johns Hopkins University, has been invited by the management of the Congress of Tuberculosis, to be held in London at the end of July, to arrange for American representation. Among those who have already signified their intention to be present are Professor Truedeau, of Massachusetts, Professor Solly, of Colorado, Dr. Herman Biggs, of New York, Dr. J. G. Adami, of Montreal, and Professor McEachran, of Quebec.

THE American Academy of Political and Social Science will hold its fifth annual meeting at Philadelphia on April 12th and 13th. Professor Samuel McCune Lindsay has been elected president of the Association by the directors in succession to Professor E. J. James, of the University of Chicago, who was the founder of the Academy and its first president, from the date of organization in 1889, until January 1, 1901.

A CIVIL service examination for the position of aid in the U. S. Coast and Geodetic Survey, with a salary of $725, will be held on April 23d. The subjects are mathematics, astronomy, physics, surveying, geography and modern languages.

MR. MARCONI has won the suit brought against him for $100,000 damages and to restrain him from further use of wireless telegraphy by the assignee of Professor A. E. Dolbear.

SENATOR SLATER has introduced a bill, at Albany, appropriating $400,000 for the use of the Palisade Commission in purchasing the Palisades. The first section of the bill is as follows:

> The sum of $400,000, or so much thereof as may be necessary, is hereby appropriated, out of any moneys in the Treasury not otherwise appropriated, for the use of the Commissioners of the Palisades Inter-State Park, to be expended in acquiring land lying between the top of the steep edge of the Palisades of the Hudson River and the high-water line of said river, and lands lying under water and riparian right adjacent thereto between Fort Lee and Piermont Creek, in such name or names and under such conditions as the commission may deem necessary or wise, and for such other purposes as the commission may deem necessary and proper in carrying out the purposes and intent of Chapter 170 of the Laws of 1900.

THE Ways and Means Committee of the Assembly of New York State has reported the bill of Assemblyman Snyder, appropriating $250,000 for the purchase of forest lands for the State preserves. Of the sum appropriated $200,000 is to be expended in the purchase of

land for the Adirondack preserve and $50,000 for the Catskill Mountains preserve.

THE Legislature of New Hampshire has rejected two bills for the preservation of the State forests. One bill provided for the restriction of lumber cutting to trees of a prescribed size. The other bill authorized a loan of $1,000,000 for the purchase of forest lands and the establishment of a forest reserve in the State.

AT the last monthly meeting of the Zoological Society of London, it was stated that there had been 118 additions to the Society's menagerie during the month of February, amongst which special attention was directed to an August amazon (*Chrysotis augusta*) from Dominica. Upon one previous occasion only had a specimen of this fine bird been received at the Society's gardens—namely, on May 12, 1865. The additions also included a Guinea fowl (*Numida meleagris?*) from Rabat, Morocco, presented to the Society by Mr. G. E. Neroutsos, British Vice-Consul at that port. The Council announced to the meeting that the King had been pleased to become patron of the Society in succession to the late Queen Victoria.

IN order to further laboratory instruction of large classes of students in physiology, Professor W. T. Porter, director of the physiological department in the Harvard Medical School, will undertake to provide reliable physiological apparatus constructed under his personal supervision. It is expected that the improvements suggested by the daily experience of the Harvard Laboratory will thus be made directly available to others; and it is hoped that by this arrangement the quality of physiological apparatus for general use will be improved and the price sensibly diminished. All communications should be addressed to Professor W. T. Porter, 688 Boylston Street, Boston, Mass.

THE following details are given in *The Forester* regarding the Act passed by the Pennsylvania Legislature which raises the Division of Forestry of the State's Department of Agriculture to the position of a Department of Forestry. In addition to the new importance which is thus given to the forest service of the State, the efficiency and strength of its organization is much increased by the Act. The department is to consist of a Commissioner of Forestry, and four others. These shall also constitute the State Forestry Reservation Commission. The commissioner is to hold office for four years and so are his fellow members of the Reservation Commission; they are not all to be appointed at the same time, however, and their terms of office so overlap that the Board will always have two members of two years' experience. The Reservation Commission is empowered to buy lands for the forest reserve, to manage them, to sell timber and to make contracts for the mining of any valuable minerals which may be found in them. The Act further specifies that the Commissioner of Forestry shall be the president and executive officer of the Forestry Reservation Commission, and also superintendent of the State Forestry Reservation, and shall have immediate control, under the direction of the Commission, of all forest lands belonging to the Commonwealth. He is empowered to execute all rules adopted by the Commission for the enforcement of laws designed to protect the forest from fire and depredation, and is also empowered to employ detective service and to make arrests. It is also provided in this Act that the kindling of fire on a forest reservation, except in accordance with the rules and regulations of the Commission, shall be a misdemeanor, for which the penalty is a fine of not less than one hundred dollars, or more than five hundred. Governor Stone has appointed, as we have already noted, Dr. J. T. Rothrock as Commissioner.

AT the annual general meeting of the Institution of Mechanical Engineers, London, Mr. W. H. Man was elected president, Mr. A. Keen, Mr. T. Hurry Riches and Mr. Bryan Donkin, vice-presidents and Sir J. Wolfe-Barry, Mr. W. Dean, Mr. H. G. Harris, Mr. A. Tannett-Walker and Sir W. T. Lewis, new members of the council. The annual report, as we learn from the *Times*, stated that at the end of 1900 the number in all classes on the roll of the institution was 3,165, a net gain of 243 members as compared with the number on the roll at the end of the previous year. The total revenue for 1900 was £9,005

8s. 1d., while the expenditure was £8,595 11s. 1d., leaving a balance of revenue over expenditure of £409 17s. The total investments and other assets at the end of the year amounted to £70,117 1s. 5d., and, deducting therefrom the £25,000 of debentures and the total remaining liabilities, £4,211 15s. 6d., the capital of the institution amounted to £40,905 5s. 11d. Of this sum £5,000 was set aside in 1897 and 1898 for the redemption of the debentures. The sum of £6,850 4s. 8d. still remained invested in railway debenture stocks and Consols, registered in the name of the institution. A total of £60,270 2s. 10d. had now been expended upon the institution-house. The award of the Willans Premium had been for the first time in the gift of the council, and, from the papers read before the institution since the foundation of the fund in January, 1895, they had selected that read in April, 1895, by Captain H. Riall Sankey, on 'Governing of Steam-engines by Throttling and by Variable Expansion,' as the most suitable for the award. With a view to the formation of a historical museum, relating to mechanical engineering progress, several gifts of value had been promised. The numerous letters which had been received from the United States evinced a thorough appreciation of the reception accorded to the members of the American Society of Mechanical Engineers by the institution at its summer meeting. The work of the graduates has been carried on with considerable success, and a number of visits were made by the graduates to works in the neighborhood of London. The council had awarded prizes to Mr. W. B. Cleverly and Mr. Brees van Homan for their papers on 'Works Management, Methods of Quick Production of Repetition Work' and 'Steel Skeleton Construction, as applied to Buildings on the American System' respectively. In consequence of a desire expressed by several members of the institution, the council communicated with the War Office in February, asking if it would be of any advantage to the Government to have the assistance in South Africa of the engineering experience of members of the institution; the reply indicated the high appreciation of the Secretary of State for War, and stated that, although arrangements had already been made, the offer would certainly be borne in mind in case circumstances should alter. The council, after consultation with officers of other institutions, had consented to take charge of the mechanical section of the Glasgow International Engineering Congress, the meetings of which would be held during the first week of September of this year. These arrangements would not interfere with the ordinary summer meeting of the institution, which would be held during the last week of July at Barrow-in-Furness.

THE home department of the Government of India has made a report of deaths from wild animals and snakes which are summarized in the London *Times*. During 1899 the number of deaths among human beings attributed to wild animals was 2,966. Fortunately, however, the number is below the average of the last four years and much lower than the number (4,283) reported in 1897. In 1899 tigers caused the death of 899, wolves of 338, and leopards of 327 human beings, while bears, elephants, hyenas, jackals and crocodiles were accountable for a large proportion of the remainder. The tiger is most destructive in Bengal, about half of the whole number of the victims of this animal being reported from that province. Man-eaters have especially troubled certain districts, and liberal rewards have been offered for their destruction. In the Bhamo district of Upper Burma a single man-eating tiger killed about 20 people. A special reward of 100 rupees was paid for its destruction. More than half of the deaths from leopards occurred in Bengal, while more than three-fourths of those from wolves occurred in the Northwestern Provinces and Oudh. Special measures were taken to hunt down a particularly destructive pack near Cawnpur. High rewards were offered, and hunting parties organized, but without much success. The loss of human life from snakes reached the high total of 24,621 a greater mortality than in any of the four preceding years. Nearly half the deaths occurred in Bengal, while the Northwestern Provinces and Oudh came next with nearly one-fourth of the total. In Bengal the relatively high mortality is attributed to floods, which drove the snakes to the highlands on which village homesteads are built. As will be observed, snakes are more

destructive of human life than are wild animals, but the reverse is true of the destruction of cattle. In 1899 no fewer than 89,238 cattle were destroyed by wild animals, and 9,449 by snakes. Of the former 37,986 fell victims to leopards, and 34,321 to tigers. The leopard is even more destructive to cattle than the tiger in Bengal. This province is the greatest sufferer from the ravages of wild animals and snakes, its loss being 30,539 cattle. Assam lost 17,010, Madras 15,592, Burma 11,016, and the Central Provinces 11,689. The number of wild animals destroyed was 18,887 and the amount paid for their destruction was 107,476 rupees. The number of snakes killed was 94,548, and the rewards paid for service amounted to 4,151 rupees.

UNIVERSITY AND EDUCATIONAL NEWS.

THE Washington State Legislature has adjourned after having made liberal appropriations for the support of education. The State University gets $270,000, the State Agricultural College $94,800, the three normal schools $93,-800, $45,000 and $40,000, respectively.

THE Indiana Legislature has appropriated $100,000 for a science building for Indiana University.

THE Ontario Government, in addition to the aid contained in the Toronto University Bill now before the Legislature, which involves the payment of about $20,000 a year for the science department, salaries and maintenance, has decided to erect a new building for the science department on the site of the old Wycliffe College, at a cost of about $200,000.

BY the will of the late George T. Bliss, of New York City, who died on March 24th, Yale University receives $50,000.

MR. JOHN D. ROCKEFELLER has offered to give Richmond College, a Baptist institution of Virginia, $75,000, on the condition that the College shall collect $25,000.

THE sum of $12,000 per annum has been subscribed for the conduct of the experimental school of Teachers College, Columbia University. It will be remembered that a building is about to be erected for this school with a gift of $100,000.

THE Lord Mayor of London presided at a meeting on March 21st, when the Earl of Roseberry delivered an address on commercial education. The object of the meeting was to call attention to the importance of higher commercial education in relation to the present position and prospects of British trade, and to take the preliminary steps to raise a fund for the establishment of additional higher commercial teaching in connection with the new London University. Toward this fund, Messrs. N. M. Rothschild & Sons have contributed £5,000.

AN influential committee has issued an appeal with the object of raising £150,000 in celebration of the jubilee of Owens College, Manchester. Fifty thousand pounds are needed to discharge debts that have been contracted and £100,000 for additional endowment. Among the objects the promoters have in view are the extinction of the debt of £22,000 on the building of the medical school; special endowments for existing chairs, including French, chemistry, education, anatomy and philosophy; the establishment of new chairs of English literature, Hebrew and architecture; the establishment of an institution for bacteriological investigation and for the study of hygiene, and of research fellowships; and the creation of a pension fund for members of the teaching staff.

FOLLOWING the action recently taken by the University of Michigan, the Faculty of the College of Science, Literature and the Arts in the University of Minnesota has voted to recommend to the Board of Regents that only one degree, that of bachelor of arts, be given hereafter. Under the present arrangement three courses are offered in the college, leading to the degrees of bachelor of arts, bachelor of literature and bachelor of science.

FOR the remainder of the college year, Mr. S. M. Coulter takes the position of instructor in botany in Washington University, vacated by the appointment of H. F. Roberts as professor of botany in the Kansas Agricultural College.

DR. V. L. LEIGHTON, instructor in organic chemistry at Tufts College, has been called to an associate professorship of chemistry at the College of Agricultural and Mechanic Arts, at Kingston, R. I.

George M. Dawson

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, APRIL 12, 1901.

GEORGE M. DAWSON.

BY the death of Dr. G. M. Dawson, the Dominion of Canada loses one of her ablest and most distinguished men of science and one whose loss will be felt for many years to come. George Mercer Dawson was the eldest son of the late Sir William Dawson and was born at Pictou, Nova Scotia, on August 1, 1849. In 1855, his father, having received the appointment as Principal of McGill College, left Nova Scotia and came to live in Montreal. The wide college grounds, lying then on the outskirts of the town and backed by Mount Royal, at that time covered with its original forest growth, formed an environment full of interest and delight to the boy, whose mind turned to the study of nature from the first, a study which was made doubly fascinating in his case by his father, who was always ready to encourage him in his work, explain his difficulties and talk with him as a friend.

At the age of ten he entered the High School at Montreal, where he took a high place among the boys of his class. There were, however, at that time, near what is now the center of the city of Montreal, a number of ponds in which the boys from the High School used to go rafting at lunch hour. On one of these occasions he received a drenching and remained in his damp clothes through the afternoon; a chill was induced, which led to spinal trouble,

resulting in years of suffering and final deformity. He consequently left school, and his education, until he was old enough to enter college, was carried on chiefly by private tutors. While not neglecting the ordinary subjects of a school curriculum, he was allowed to follow out lines of study in which he found a particular interest and in this way learned many things which were later of the greatest value to him. Surrounded by books, chemical apparatus, paints and pencils, the days were never too long, and photography, bookbinding, painting magic lantern slides, pyrotechny and even cheese-making were among his many occupations. He seemed to absorb knowledge rather than to study, and was always cheerful, amusing and popular, other boys flocking round him and invariably submitting to his unconscious leadership. At times he suffered much pain and was deprived of many things dear to boys, but was never heard to complain. When quite a lad he often accompanied his father on his geological excursions with the students of McGill College on Saturdays, and even on longer expeditions to Murray Bay, Gaspe and the Joggins, and was always a helpful and bright companion.

At nineteen he had recovered his health and entered McGill College, where he studied for a year, and in the following year entered the Royal School of Mines in London. He went to England in a sailing ship, for the benefit of the longer voyage, and on the way over amused himself by studying navigation under the captain. Years later when he chartered a schooner, in order to make an examination of the Queen Charlotte Islands, the captain of the latter, proving to be drunken and unsatisfactory, was dismissed, and Dawson navigated the schooner himself during the remainder of the trip, and this on a deeply indented and dangerous coast, of which at that time no chart existed.

At the Royal School of Mines he took the regular course, extending over three years, taking the Duke of Cornwall's Scholarship, and the Forbes medal and prize in paleontology and natural history. While at the Royal School of Mines he paid especial attention to the study of geology and paleontology under Ramsay, Huxley and Etheridge, and also devoted much time to the study of chemistry and metallurgy in the laboratories of Frankland and Percy.

Returning to Canada, he was engaged for a year in mine surveys in Nova Scotia and in lecturing at Morrin College, Quebec, and in 1873 was appointed Geologist and Botanist to Her Majesty's North American Boundary Commission, which was to fix the boundary line from the Lake of the Woods to the Rocky Mountains, and which had been at work for over a year. There are but few corners of the earth which now appear so far off as the great Northwest did at that time—a veritable *terra incognita.* Fort Garry, now the city of Winnipeg, was the last point of civilization and the 49th parallel had to be traversed on horseback or on foot, the provisions and materials being taken along in Red River carts. The difficulties now experienced in traversing that district were then increased by its remoteness from civilization and the fact that it was unexplored. In summer there was not only the scorching heat of the Plains, but the prairie fires, the difficulty of procuring and carrying firewood, the scarcity of water, and, in the late autumn, the cold with all its accompanying inconveniences. Notwithstanding these difficulties, however, during the two years in which he was a member of the Boundary Commission, he accumulated materials for an elaborate and very valuable 'Report of the Geology and Resources of the Country in the Vicinity of the 49th Parallel,' accompanied with maps and many illustrations, which was published in Montreal in 1875. In connection with

this work he also prepared a report on the Tertiary Lignite Formation, a memoir on the 'Superficial Deposits of the Central Region of North America,' and papers on the 'Locust Visitations,' on the 'Fresh Water Sponges of Canada' and on the 'Fluctuations of the American Lakes.'

When the work of the Boundary Survey was brought to a close, he was appointed, in 1875, to the Staff of the Geological Survey of Canada, and, in 1883, on the retirement of Dr. Selwyn, he succeeded him as Director of the Survey, which position he held at the time of his decease. His field work, while connected with the Geological Survey, was carried on chiefly in British Columbia and the Northwest Territories, and the excellent character of this work contributed largely to the great development of the mining industry in these parts of the Dominion in recent years.

Dr. Dawson also rendered important public service in connection with the Behring Sea arbitration. As one of the British Commissioners he spent the summer of 1892 in the Behring Sea region, for the purpose of inquiring into the facts and conditions of seal life. The report of the Commission constituted the case of Her Majesty's Government, and I remember hearing at the time a high tribute paid to Dr. Dawson's ability by one of the gentlemen connected with the United States side of the case, in the statement that had it not been for Dr. Dawson's evidence and arguments, a finding much more favorable to the United States would probably have been secured. In connection with his services on this arbitration he was made a Companion of the Order of St. Michael and St. George (C. M. G.).

He usually enjoyed excellent health and had great capacity for hard work, but he succumbed very suddenly, on the 2d of March last, to an attack of acute bronchitis after an illness of but two days.

Dr. Dawson was a prolific writer. In addition to his numerous and voluminous official reports, he contributed many papers on geological, geographical and ethnological subjects to the scientific magazines and to the Transactions of various learned societies, both on this continent and in England.

He received the degree of D.Sc. from Princeton, and the degree of LL.D. from Queen's University in 1890 and from McGill University in 1891. In the same year he received the Bigsby gold medal from the Geological Society of London for his services to the science of geology, and was elected a Fellow of the Royal Society. In 1893 he was elected President of the Royal Society of Canada. In 1896 he was President of the Geological Section of the British Association for the Advancement of Science at its Toronto meeting, and was last year President of the Geological Society of America. His presidential address, delivered on retiring from the latter position, appeared in a recent number of SCIENCE. In 1897 he was awarded the gold medal of the Royal Geographical Society. He also received many other distinctions which cannot here be mentioned.

Dr. Dawson was a man of more versatile gifts than his father, but like him possessed of an unusual combination of scientific insight, literary ability and administrative capacity. He was a man of broad views, clear and judicial frame of mind, modest and retiring, but withal an excellent conversationalist. He won the esteem of all who knew him, and his loss will be keenly felt by his very large circle of friends.

FRANK D. ADAMS.
McGILL UNIVERSITY, MONTREAL.

*STATE NATURAL HISTORY SURVEYS.**

A GEOLOGICAL survey of Wisconsin, very complete and careful for the time, was com-

* Abstracts of addresses made before the Naturalists, meeting in Chicago, December, 1900.

pleted in the year 1878. During the following twenty years no investigations of this character were carried on in the State. In 1897, however, the Legislature organized the present Geological and Natural History Survey and gave to it for the first two years an appropriation of $5,000 annually, which was doubled during the second biennial period. The government of the Survey is in a Board of Commissioners, consisting of the governor of the State, the president of the State University, the State superintendent of Public Instruction, the president of the Commission of Fisheries, and the president of the Wisconsin Academy of Sciences, Arts and Letters. The director of the survey from the first has been E. A. Birge, professor of zoology in the University of Wisconsin. The work of the Survey has been done along three lines: economic, scientific and educational.

The first piece of work of economic importance was the investigation of the building stones of the State, to which two years were devoted by Dr. E. R. Buckley, who is in charge of this department, and, as a result, a full report on the building stones was published as a bulletin of the Survey in 1899. After the completion of this work, Dr. Buckley turned his attention to the clays and the clay industries, on which he is still engaged. A general report on this subject will appear during the present winter, and the work will be continued probably for at least a year or two in the future. The geological structure of the Keweenawan, or copper-bearing rocks, of Douglas and adjacent counties of northern Wisconsin has been worked out by Professor U. S. Grant, and a preliminary report has been published.

Of the several scientific investigations, the most important is the geology of the crystalline rocks in the central part of the State—a region which was almost entirely uninhabited at the time of the earlier survey. Its investigation has been assigned to Dr. S. Weidman, who has been carrying on field work since the organization of the Survey and who will prepare a complete report of the geology of the region when he has completed the task of working out, in the field, the difficult and intricate relations of the rocks.

Another line of work has been on the lakes which are so abundant in Wisconsin. A hydrographic survey has been made of more than 60 of the more important lakes in the southeastern part of the State, and maps of these lakes have been published. The investigation of the biology of the waters has been fairly begun. The physica geography of the lake region of southern and eastern Wisconsin is now being studied by Mr. N. M. Fenneman.

The first educational bulletin has recently been published by Professor R. D. Salisbury, on the physical geography of the region about Devil's Lake. This is intended to set forth the geography and the surface geology of the region in such a way as to bring out the principles of physical geography involved, so that the book will be primarily of value to the teachers and students of the subject, but it is also a contribution to our knowledge of that region.

This brief notice touches only the most important directions in which the Survey has been working, leaving unmentioned many subjects to which less attention has been given.

So far as the experience of the Wisconsin Survey goes, it appears that the State is quite willing that a considerable amount of money should be devoted to investigations whose value is scientific in the fullest sense of the word, and it also expects a considerable amount of attention to be given to subjects of economic value and of immediate practical importance. This seems to me to be entirely right. The State has a right to expect an economic return for money expended in a State survey, especially as there are

subjects of economic value which demand immediate investigation and whose study is the duty of a survey. On the other hand, the Survey ought not to allow its attention to be directed to subjects of immediate economic interest only, since, as we all know, the pure science of the present becomes the applied science of the future, and it is eminently the task of the Survey to work for the future as well as for the present. The Wisconsin Survey has endeavored to fulfill both these requirements, so far as the means at its disposal would permit, and its efforts have been fully endorsed by the State.

E. A. BIRGE.

UNIVERSITY OF WISCONSIN.

THE Natural History Survey of Minnesota is being carried on in pursuance of an act approved in 1872, and entitled "An act to provide for a geological and natural history survey of the State and to entrust the same to the University of Minnesota." In accordance with this law the Board of Regents of the University at once appointed Professor N. H. Winchell geologist of the Survey and placed the work under his supervision. The funds for carrying on the work have been almost wholly derived from the sale of so-called 'State salt lands' set aside for the Survey. After about 20 years of good work by the geologist, the geological work has been ordered to be brought to a close and the natural history has been taken up, with the professors of botany and zoology in charge of the botany and zoology respectively.

The law creating this Survey is so broad in its scope that so-called purely scientific investigations are as incumbent upon those in charge of the work as the so-called economical. Accordingly we do not at present divide this work into scientific and economical problems, but try to do scientifically everything we undertake to do, whether it has an immediate practical bearing or not. Economical and practical questions are by no means neglected, and the plans at present being followed contemplate reports that will be of educational and scientific value, as well as a handy source of information to the citizens of the State.

On the zoological side the vertebrates are at present receiving the most attention. So far as possible complete accounts of certain more or less typical species, and species that for one reason or another are of special interest and importance, are being prepared in connection with the more general reports. These individual biographies, as they might be called, are intended to serve as guides and reference texts in the schools of the State. The invertebrates are not being neglected, though with the exception of one or two groups they are not receiving special attention at present. Plankton work can not be said to have received any serious consideration, and probably will not as long as more promising and less 'killing' fields are as plentiful as they are.

In reply to questions and suggestions, it was stated that both the botanist and zoologist made it a point to send their reports, not only to all the schools of the State, but so far as possible also to all the newspaper offices in the State.

An examination of Minnesota Plant Life, issued by the botanist of the survey, will convince the most skeptical that State reports can be issued in the best typographical style. This matter, however, demands special attention and experience.

In consequence of the close connection between the University and the Natural History Survey, the biological departments of the University have become the bureau of information on natural history questions for the entire State, and the professors of botany and zoology annually answer hundreds of letters—yes, in some years, thousands.

The matter of cooperation between the

surveys of the different States has come up frequently, but I am not sure that we are ready for any definite plans. It would seem that cooperation along some lines at least would lead to most valuable results, but how to adjust these so differently organized surveys is much more difficult than picking out the problems. I am inclined to believe that we shall have to go over our fields independently at first and look toward cooperation later on. In the meantime suggestions and discussions and reflection should not be set aside altogether.

H. F. NACHTRIEB.
UNIVERSITY OF MINNESOTA.

IT is to be regretted that Professor Forbes is necessarily absent from this meeting, since he only can adequately discuss matters connected with the Natural History Survey of the State of Illinois. It is to his energy and foresight that the Illinois State Laboratory of Natural History, which is charged with its accomplishment, owes its origin, some twenty-five years ago, and it is to his oversight and direction that its success is due.

The conditions affecting the biological survey of Illinois differ materially in several particulars from those existing in Minnesota and Wisconsin. Illinois has no State geologist nor State geological survey, so that from its beginning the biological survey has been free from some of the difficulties experienced in a few of the neighboring States.

In 1877 the Legislature established what is known as the Illinois State Historical Library and Natural History Museum, at Springfield, and the Illinois State Laboratory of Natural History, at Normal, Illinois, with Professor S. A. Forbes as its director. The State Laboratory was established with several functions to perform. The law provided that by it the museum at Springfield should be supplied with material illustrating the fauna of the State; that educational institutions and high schools should be supplied with material for instructional purposes; and besides these educational activities, a State survey of the animals and cryptogamic plants was to be carried on; and, finally, certain studies of an economic character were to be made with reference to the food of fishes and of birds. In 1883 the director was made State Entomologist, and for a number of years subsequently there was no sharp division between those operations of the State Laboratory carried on in connection with economic entomology and those for which the institution was originally established. In 1885 the State Laboratory was moved to Urbana in consequence of the appointment of its director to the chair of zoology in the University of Illinois. From 1883 to 1893 the Natural History Survey work was somewhat intermittent in character, but with the establishment of the Biological Station on the Illinois river, the work has been carried on continuously along the lines originally intended. The appropriations have in most cases been reasonably liberal, and have gradually increased from $3,000 per annum to nearly $10,000, aside from the appropriations for economic entomology. At no time has the State Laboratory had the backing of any scientific society or of any other association in any way helpful in securing legislative appropriations. It has at all times stood strictly on its merits and the value of the work accomplished, and its continual growth is due to the confidence which members of the Legislature have felt in the integrity of the director as a man, and in his energy and ability as a scientist.

The laws under which the State Laboratory was founded and has been supported seem to emphasize the educational part of its duties rather than the scientific and economic features. Professor Forbes's working definition of 'survey' involves more than a

mere census of animals and plants or a publication of lists showing local and geographical distribution. It is broad enough to include matters of an ecological character, and this view has largely determined the general plan of operations. It would have taken less time to send the material of the various collections to specialists at Washington, or elsewhere, and have identifications made by them, than to collect the necessary literature and allow the time and expense involved in the training of a group of specialists on the staff of the State Laboratory; but the former plan would have resulted simply in the accumulation of named material as a basis for lists of plants and animals with reference to local and geographical distribution, while the latter course is essential to a natural history survey in a wider sense. The director regards as one of the most important objects to be attained by the State Laboratory investigations, the presentation of the knowledge obtained in a form accessible to all interested intelligent citizens of the State. Much remains to be done before this work will be completed. Most of the literature thus far published by the State Laboratory has been more or less technical and written with reference to the specialist, but such material is to be considered as a sort of by-product incidental to the prosecution of the more essential duties.

Two important lines of work are now in progress. One of these, the ichthyological survey, has received much attention during the past two years and will result in the publication of a comprehensive report on all the fishes occurring within the borders of the State, in which as full an account as practicable of life histories, habits and conditions of environment will be given in addition to the ordinary descriptive matter. Each species is to be illustrated by colored plates made from living specimens. I have brought, for the inspection of those interested, a few of the drawings already prepared, which reflect great credit on the State Laboratory artist, Miss Lydia M. Hart, by whom they were made.

Another line of work which is being vigorously prosecuted is the study by Dr. Kofoid of the plankton material collected from the Illinois river at frequent intervals during a period of nearly five years. The work of counting has been completed, and the data are being got into proper form as rapidly as possible. As a result of this work much interesting and important knowledge is being gained concerning the life histories, seasonal distribution, relative numbers and sequence of succession of many of the minute organisms composing the river plankton. As most of the counting work has been done since Dr. Kofoid made a preliminary report in this place a year ago, I may mention that some interesting facts stated by him in a tentative way have been confirmed. For example: (1) the marked constancy in the seasonal recurrence of many species, with their maximum and minimum numbers appearing annually within narrow time limits—perhaps an adaptation to definite temperature conditions; (2) the constancy of a spring and fall maximum for many species, the latter secondary—these maxima indicating perhaps an adaptation to the mean temperature of the year; (3) the evidence of the extreme variability of some of the limnetic forms and the probable genetic connection within the season of a number of supposed species—as in the case of *Brachionus bakeri* and its related forms and of *Dinobryon*, composite colonies of the latter being often found, different portions of which are made up of very different types of individuals, types which more frequently will be found in small colonies of homogeneous character and which have received various specific names; (4) the presence of a minute plankton flora occurring within about the same seasonal limits

as the foliage of the trees and disappearing as abruptly. For the greater part these forms are so minute that they ordinarily escape the silk net, and it is only in collections made by some filter method that an adequate idea of their importance can be gained. Detailed examination of the filter-paper catches tends to confirm the criticisms of Dr. Kofoid with reference to the dependence on collections made by the silk net alone. The loss by leakage or escape is often volumetrically as well as numerically very large. Other interesting facts might be referred to, but there is scarcely sufficient excuse for it in this connection.

A paper of systematic character on the leeches of the State Laboratory collection, by Mr. J. Percy Moore, is now in press, and an article on the Odonata, by Professor Needham and Mr. Hart, is nearly ready for the printer. Aside from numerous publications of an economic entomological character there have been published two quarto volumes on the birds of the State, and five volumes of the *Bulletin of the Illinois State Laboratory of Natural History.*

As to future work, it is probable that a comprehensive entomological survey entirely distinct from economic investigations will be undertaken in the near future, and work is now in progress on the first one of a special series of bulletins of what may be termed an educational nature, in which the object will be to treat various groups of animals in such a way as best to meet the needs especially of teachers and students of zoology in high schools and colleges. These bulletins, while giving descriptions and synoptic keys, are at the same time to include such physiological and ecological matter as will make them useful. It is intended that they shall be scientific, but written for others than specialists.

While cooperation in the work of the various State surveys would theoretically have several advantages, it practically seems well-nigh unattainable because of the great difference in the conditions governing the action of each. Efforts have been made within the past few years to bring about such cooperation, but without result. If it were possible to have the energies of different surveys directed in part along similar lines of work synchronously, so that one specialist might work up a given group of animals for several States, there would be evident economy in time and money; or such special educational publications as those previously referred to might, with comparatively small additional outlay of time and money, be adapted to use in several States instead of but one. It might be greatly to the advantage of the surveys in different States if competent men in charge of the biological departments of some of the educational institutions of the State should become interested and responsible for the working up of special groups; and as far as Illinois is concerned, Professor Forbes would be greatly pleased if such cooperation between the State Laboratory and some of the working biologists in the State might be accomplished. He would willingly procure necessary literature and aid in the matter of collections, and although not ready to make unconditional promises of compensation, would, I am sure, feel warranted in cooperation of a financial, as well as of a scientific, sort. Here we meet with one of the great difficulties in the economical prosecution of such survey work. The instruction in our leading institutions is so exclusively along morphological and physiological lines that the men coming from such institutions are not prepared for the kind of work required in surveys, and much time and expense is involved before they can accomplish results. A vacancy on the State Laboratory staff is often a serious matter, because of the impossibility of finding men already prepared to prosecute such work. FRANK SMITH.

UNIVERSITY OF ILLINOIS.

THE TRAINING OF AN ELECTROCHEMIST.

AT the meeting of the German Electrochemical Society in Zürich, last August, Professor Richard Lorenz,* at the request of the Society, read a paper on the kind of training which is desirable for an electrochemist. The paper contains much which is suggestive in reference to the training of chemists in general, and calls attention to certain defects in the present method, especially as applied in many of the German universities.

Lorenz first raises the question as to whether electrochemists are entitled to recognition as representing a separate and distinct branch of science, and, notwithstanding the fact that they have not yet received such recognition in all the schools, answers the question, of course, in the affirmative. The battle in reference to the existence and recognition of electrochemistry is, in most places, at an end. Its chief enemy is the one-sided manner in which chemists, until recently, have been trained; and this one-sided method of training still obtains in some universities. We know, to-day 'that a chemical doctor well trained in all directions' is often nothing but a special organic chemist. Even if in some cases the candidate has learned a little analytical chemistry in order to be able to pass certain examinations outside of the university, he knows absolutely nothing of that fundamental branch of science—physical chemistry—and his knowledge of inorganic chemistry is so fragmentary that it cannot be called scientific—of the science of inorganic chemistry he knows essentially nothing.

It is quite different at certain polytechnic institutions where inorganic chemistry is constantly introduced in connection with technical chemistry and metallurgy.

Since electrochemistry, as is well known, is one of the best developed branches of physical chemistry, the electrochemist should be trained in physics and in chemistry. Organic chemists should also know much more physics than is usually required of them.

Electrochemistry is also very closely connected with inorganic chemistry, and the rise of physical chemistry and electrochemistry in Germany has reawakened an interest in inorganic chemistry, which had almost entirely disappeared. Modern electrochemistry is an exact science, and rests on a mathematical basis. Every electrochemist must, therefore, be trained in the elements of the higher mathematics, and be able to use the differential and integral calculus. Later he must apply thermodynamics and chemodynamics to the problems as they arise. It is not until mathematics is applied to special problems that its significance is appreciated by the investigator of nature.

It is difficult to lay too much stress on the importance for an electrochemist of a general training in physics. He should be trained first of all in mechanics, then in sound that he may become familiar with the conception of wave-motion, also in heat, light, electricity and magnetism.

The physicist, in training a skilful electrochemist, should not ask "What use can he make of my knowledge?" and he should not adapt his teaching to special needs. The electrochemist, as well as the practical chemist, can use all physics. They may have to do with the magnetic properties of the atoms, or with heat phenomena, or with photometric relations, or with the kind and nature of the vibrations in an ozonator, or with fusion, evaporation and specific heats in the electric furnace. If the physicist were to consider simply the 'needs of the electrochemist,' he would teach him simply the chapters which pertain to electrical measurements. This would be a serious error and would retard the development of electrochemistry along broad

* *Ztschr. elect. Chem.*, **7**, 201.

and general lines. The need of the electrochemist is for the broadest possible development in the science of physics.

Analytical chemistry is of fundamental importance for the electrochemist. He should be able to make more or less complex analysis not only accurately, but rapidly. Speed in carrying out an analysis is often a necessity.

Inorganic chemistry is still taught but little at the German universities, and this is, of course, fundamental for the electrochemist. Some little inorganic chemistry is taught under the head of 'general chemistry.' In other places some lecture experiments are shown, and equations written, showing the transformations of substances. In other places inorganic chemistry is dealt with from the standpoint of the modern theory of ions. But in the last decade inorganic chemistry has developed as rapidly and made as great strides as theoretical chemistry. Thus, the vast amount of knowledge which we have in reference to the formation and decomposition of double salts, the beautiful experiments in the field of complex compounds, the extension of our science to the rare gases and rare earths, the reactions of substances at high temperatures as studied by the French school, the transformation temperatures and, finally, the fundamental relations of all phenomena to the Periodic System, are seldom dealt with. We need a place in which these matters can be *really systematically discussed* and brought to their attention. We should teach the students fewer formulas and more about the *real knowledge of the properties of all the elements and compounds.*

We know from the lectures of Van't Hoff on 'The Increasing Importance of Inorganic Chemistry,' and of Hittorf on 'The Necessity of Establishing Special Chairs for Inorganic Chemistry in the German Universities,' that the chairs of inorganic chemistry have been occupied almost exclusively by organic chemists, whose interest and indeed whose knowledge were not in this field. As co-editor with Küster of the *Zeitschrift für anorganische Chemie,* I have had the very best opportunity to observe how great has been the growth in this field. If any one should think that the reason for desiring new chairs of inorganic chemistry to be established is in any way connected with the desire that certain individuals should have full professorships in inorganic chemistry, he has not obtained his information from the proper source.

In reference to the training of the electrochemist in organic chemistry, that is already amply provided for, and nothing further need be said concerning it. The electrochemist should also study as subordinate subjects mineralogy, crystallography, geology, etc.

Lorenz then takes up the question as to how far the electrochemist should be familiar with mechanics, a knowledge of machines, mechanical drawing, etc. He recognizes the force of Ostwald's warning, that the student should not have too many subjects, but under present conditions electrochemists, in out-of-the-way places, may have to fill so many rôles that a knowledge of these mechanical matters is often a necessity.

In reference to the special electrochemical training; instruction should be given, as Knorre has already pointed out, in general and technical electrochemistry, in general physical chemistry, as well as in thermochemistry, chemical dynamics, organic electrochemistry, chemical thermodynamics, etc. The student should be so trained in mathematics that these subjects can be dealt with mathematically. The best means to train and develop an electrochemist, in general, is the carrying out of a scientific investigation, as Ostwald has already maintained.

Lorenz then takes up the discussion of

the work which should be done by the electrochemist in the laboratory, and finally decribes the training which the students in the Polytechnic Institute in Zürich receive. The point which is of chief interest here is that *mathematics is required for every chemist,* and physics is introduced in the broadest way into the course of every chemist.

The scientific importance of this address is much greater than would be implied by its title. The question arises whether much that was said by Lorenz does not apply to other branches of science or, perhaps, to all, although it is true that some of the natural sciences, chiefly on account of the relative complexity of the phenomena dealt with, are not yet sufficiently advanced to enable the mathematical methods to be extensively applied to them, yet they are all rapidly approaching that stage which we may describe as the mathematical.

Take as an example the science of chemistry. Physics, the furthest developed of all the natural sciences, has long since become an exact or mathematical science. It has been only a short time since a student could get on fairly well in most branches of chemistry without any knowledge of the higher mathematics. But how different to-day? A chemist now who is not familiar with the calculus can have no adequate conception of the theoretical side of his science, as Van't Hoff and others have repeatedly pointed out. In inorganic chemistry, at least in its latest developments, the calculus is absolutely essential, since inorganic chemistry is touched at all points by physical chemistry, and who can know anything of physical chemistry without the calculus. Take on the other hand organic chemistry. There are certain very important phases of this subject into which the higher mathematics has not yet entered; but in the study of the velocity of organic reactions, of the chemical dynamics and statics of such reactions, not only the calculus is required, but also a fair knowledge of thermodynamics. In physical chemistry a knowledge of the higher mathematics and of physics is just as essential as a knowledge of chemistry itself, and thus it goes through the whole field of chemistry.

A student who starts out to-day to become a chemist without a good knowledge of physics and mathematics is hopelessly handicapped at the outset, no matter to what division of chemistry he may turn his attention.

In other branches of science we already see the dawn of the exact or mathematical period. Take physiology, one of the most complex of the biological sciences. Certain phenomena of life have already lent themselves to mathematical treatment, as is shown by the work of Loeb and others. The application of physical chemistry to physiology seems to mark the introduction of the mathematical method in dealing with the physics and chemistry of life.

Take morphology—the work of Davenport shows that even structure can be treated by the exact method, and makes it probable that the morphologist in the future will have to look to his higher mathematics.

Other branches of science might be cited, but these suffice to show how rapidly the mathematical method is coming to be applied to all scientific knowledge. *Perhaps the most distinguishing feature of scientific study at the beginning of the twentieth century is the introduction of the mathematical method into all those branches of knowledge which are sufficiently developed.*

One of the most important features, therefore, in scientific training to-day is a thorough course in the elements of the higher mathematics, and this should be followed in every case by an equally thorough course in physics. The student who is not thus equipped can never hope to pass

beyond empiricism, nor obtain any insight into the real meaning and relations of natural phenomena.

HARRY C. JONES.

APPROPRIATIONS FOR THE U. S. DEPARTMENT OF AGRICULTURE.*

THE passage of the agricultural appropriation act for the year 1901–1902 marks an epoch in the history of the development of the national Department of Agriculture. Not only does it carry the largest appropriation ever made for the Department and provide for future extension of its work in various lines, but it inaugurates a scheme for the partial reorganization of the scientific branches of its work. Three of the present divisions are raised to the grade of bureaus, and a number of other divisions are associated in one large Bureau of Plant Industry, corresponding in a general way to the present Bureau of Animal Industry.

Starting first as an appendix to the Patent Office for the distribution of seeds, the Department of Agriculture was formally organized in 1862 as an independent department in charge of a commissioner, and in 1889 was raised to the dignity of an executive department. The passage of the Hatch Act providing for agricultural experiment stations about that time increased its responsibilities and extended its field of usefulness.

The growth of the Department has been steady and uninterrupted. The importance of its work has been recognized by steadily increasing appropriations, and the relations maintained with the experiment stations furnish a means of carrying its investigations into every section of the country, in cooperation with these institutions, and serve to broaden its influence. As an institution for agricultural investigation it is now without a counterpart in any country, and there are few, if any, scientific institutions which include so large an aggregation of scientists and experts devoting their attention to investigations and research. The Department is coming to be generally recognized as one of the great scientific institutions, not alone in this country, but of the whole world. The formation of bureaus is a fitting step at this juncture, for it is a recognition of the growth which has been made and the need for a more compact form of organization. The creation of these four new bureaus, in addition to the Weather Bureau and the Bureau of Animal Industry, is a following out of the general divisions into which the subject of agriculture seems logically to fall, associating such lines of work as relate closely to each other and providing for the closest cooperation practicable among them.

The new Bureau of Plant Industry embraces the divisions of Botany, Vegetable Physiology and Pathology, Agrostology, Pomology, and Gardens and Grounds, and is under the directorship of B. T. Galloway. To this bureau has also been assigned the Section of Seed and Plant Introduction, together with the general supervision of the experiments in tea culture. A horticulturist will be added to the list of specialists, with the intention of developing the work of investigation along that line. From the standpoint of administration the arrangement will be an economy of time and will give greater opportunities for investigation to the chiefs of the divisions.

In recognition of the plan for a systematic survey of agricultural soils and for extension of the work in forestry, the divisions of Soils and Forestry receive bureau organizations and are raised to that designation. The fourth bureau provided for is the Bureau of Chemistry, to which additional scope will be given.

* From proofs of the 'Experiment Station Record,' Vol. XII., No. 9.

The appropriation act makes frequent mention of cooperation between the different divisions of the Department and also with the agricultural experiment stations. The establishment of the Bureau of Plant Industry will favor the extension of the cooperation and will assist in adjusting the lines of work and preventing any tendency to duplication.

Of the new bureaus the Bureau of Plant Industry receives the largest appropriation, namely, $231,680. The amounts appropriated for the different lines of investigation in charge of this bureau, aside from certain salaries, are $60,000 for investigations in vegetable pathology and physiology, $20,000 for pomological investigations, $45,000 for botanical investigations and experiments, $20,000 for grass and forage plant investigations, $20,000 for seed and plant introduction, $7,000 for tea-culture experiments (an increase of $2,000), and $20,000 for gardens and grounds. The total appropriation for the Bureau of Plant Industry represents an increase of $61,900 over the combined appropriations for the previous year of the divisions associated in it. A new feature of the botanical investigations is the study of useful plants of the tropical territory of the United States, together with plants likely to be of value for introduction into those sections. Furthermore, investigations are to be made on 'the varieties of wheat and other cereals grown in the United States and suitable for introduction, in order to standardize the naming of varieties as a basis for experimental work of the State experiment stations and as an assistance in commercial grading'; and in cooperation with the Bureau of Chemistry, the cause of deterioration of export grain, particularly in oceanic transit, is to be investigated, together with means of preventing such loss. Special mention is made in the appropriations for this bureau of the employment of scientific aids, a class of employees drawn from the agricultural colleges, which has previously been arranged for in the Department.

The Bureau of Forestry receives $185,440, an increase of $105,440 over the previous year. The appropriation for the Bureau of Soils is $109,140, which is an increase of $77,840. This is to enable an extension of the tobacco investigations, which remain in charge of this bureau, and the investigation and mapping of soils in the United States. The Bureau of Chemistry receives $35,800, and in addition to its other duties is charged with the investigation of food preservatives and coloring matters 'to determine their relation to digestion and to health and to establish the principles which should guide their use.'

The Weather Bureau receives increased appropriation for general maintenance, and $46,000 for the erection and equipment of buildings in six different places, and for laying a cable between the mainland and Tatoosh Island, Washington, making the total appropriation $1,148,320. The maintenance fund of the Bureau of Animal Industry is increased $50,000, and the inspection work is extended to include dairy products intended for exportation to foreign countries. Such products, the same as meats, may be marked, stamped or labeled, so as to secure their identity and indicate their purity and grade. This is an entirely new provision, which it is hoped will tend to place American products on a better footing in foreign markets. An appropriation of $25,000 is made, in addition to one of $50,000 last year, for animal quarantine stations, giving a total for the bureau of $1,154,030.

The appropriations for agricultural experiment stations have reached the sum of $789,000, including $33,000 for the Office of Experiment Stations, as heretofore, and $12,000 each for stations in Alaska, Hawaii and Porto Rico. The Hawaii station

will be located near Honolulu on a government reservation originally set apart by the provisional government for the use of an experiment station. It is intended to make the work there supplementary to that of the experiment station which has been maintained by the Hawaiian sugar planters, and attention will be given to other field crops and the development of animal industry and horticulture. Jared G. Smith, recently in charge of the Section of Seed and Plant Introduction of this department, has been placed in charge of the Hawaii station, and will take up the work there about the middle of April. Fifty thousand dollars was appropriated to continue the irrigation investigations, and $20,000 for nutrition investigations, the latter being an increase of $2,500.

The Division of Statistics receives $156,160, the same as last year, the Division of Entomology $36,200, and the Division of Biological Survey $32,800. The fund for publications is increased by $50,000 for farmers' bulletins and a small amount for distribution, making the total for the Division of Publications $198,020 aside from the general printing fund, $110,000. Other appropriations are as follows: seeds, $250,000, exclusive of the $20,000 mentioned for seed and plant introduction, an increase of $100,000; library, $16,000; public-road inquiries, $20,000, an increase of $6,000; investigating the production of domestic sugar, $5,000; Arlington farm, $10,000; office of the Secretary, $71,670; Division of Accounts, $18,900; Museum, $2,260, and contingent expenses, $37,000. The grand total, including the regular appropriations for the experiment stations, is $4,582,420, an increase of $558,920 over last year.

An important item of the appropriation act is the authorization of the Secretary of Agriculture to submit plans and recommendations for a fireproof agricultural building, to be erected on the grounds of the Department, and appropriating $5,000 for the preparation of such plans. The Department long since outgrew its original accomodations, and for years has been badly cramped for room. The present main building has been condemned as unsafe, and from the nature of its construction the risk of fire has always to be met. Besides erecting a number of small buildings, which are mere temporary makeshifts, it has been necessary to rent several residences in the neighborhood and adapt them to laboratory and office purposes. Laboratory buildings for the Division of Chemistry and the Bureau of Animal Industry have been specially erected by private parties and rented to the Department. The amount now paid for rental for these buildings, together with the additional expense required for watchmen, aggregates about $10,000 annually. The position to which the Department has now attained, the demands of its work, and the safety of its library records and collections, make a modern agricultural building a practical necessity if not an imperative need.

E. W. Allen.

THE REDUCTION TO ABSURDITY OF THE ORDINARY TREATMENT OF THE SYLLOGISM.

The traditional treatment of the syllogism errs both by redundancy and by insufficiency—that is to say, the validity of the syllogism can be tested by a far simpler method of procedure, and, on the other hand, the ordinary method fails of application to a vast number of pairs of propositions which are nevertheless the premises of a valid syllogism. In the first and second moods of the first figure the syllogism is in what may be called its primitive form—it is doubtless the only form in which it is used by children and savages; but there is another form, in which negative modes of expression are given free play, which is far

superior to it in facility of manipulation. This superiority has its source in the fact that of the eight (not four, to which the ordinary logic has reduced the forms of speech) propositions necessary to a complete description of the universe,—

a. all a is b,	$\bar{a}$. not all a is b,
$\bar{u}$. none but a is b,	u. some besides a is b,
$\bar{i}$. no a is b,	i. some a is b,
o. all but a is b,	$\bar{o}$. not all but a is b,

it is the last four that possess the great advantage of being symmetrical (that is, of having subject and predicate amenable to the same rules of manipulation), and of these it is 'no a is b' and 'some a is b' that possess the other advantage of naturalness. These last should therefore be regarded as the canonical form of the proposition; and correspondingly, the ideal form of the syllogism is that in which it appears as a statement of the impossibility of concurrence of the premises and *the denial of the conclusion* of the ordinary syllogism. The canonical form of the syllogism is therefore this:

no a is b,
no c is non-b,
and some a is c

are inconsistent (*or cannot all three be true together*). This may be called the Inconsistency, or the Incompatibility, or, perhaps, the Antilogism. But in this all three propositions play an exactly similar rôle—there is no distinction between premises and conclusion, and it is therefore the one single form to which *every* syllogism may be at once reduced, provided we (1) express every universal proposition in the negative form, no p is q, (2) express every particular proposition in the affirmative form, some r is s, and also (3) deny the conclusion. When thus reduced to the form of an inconsistency, the rule for validity is this: of the three propositions, two are universal and one is particular; each two propositions have one and only one term in common; the term common to unlike propositions appears with like signs and the term common to like propositions appears with unlike signs. (Thus in the above typical form, b and non-b are common to the two universal propositions, but a, or c, of like quality, are common, respectively, to the particular and either universal.)

Any given statement of fact may be expressed in terms of any one of the four different copulas given above, or again, with the aid of the special terms *the non-existent* and *the existent* (0 and ∞ in Symbolic Logic), it may be expressed in four different ways with one and the same copula; thus

all a is b,	nothing is a and $\bar{b}$,
all $\bar{b}$ is $\bar{a}$,	everything is $\bar{a}$ or b,

are four different forms of one and the same statement of fact (expressed in the four possible combinations of two terms and their negatives); but in the two symmetrical copulas (no a is non-b, all but non-a is b)* the four forms all become practically identical. There are therefore ten $(4 + 4 + 1 + 1)$ essentially different ways of saying one and the same thing. As each proposition of the Inconsistency can be expressed in any one of these different ways, and again as each Inconsistency can appear in the form of the universal or of the particular syllogism, the total number of possible syllogisms (when full latitude is given to mode of expression) is two thousand $(10 \times 10 \times 10 \times 2)$. An example of one of these outlying forms is this: none are athletic and unhealthy, none are healthy and unhappy, hence all are either

* It is, to a certain extent, matter of taste whether

no a is b,	nothing is both a and b,
no b is a,	a which is b is non-existent,

be regarded as different forms or not,—and so 'all but a is b,' etc. If it be preferred to consider them as different, then the entire number of propositional forms is 16 instead of 10 and the number of different syllogisms is $16 \times 16 \times 16 \times 2 = 8192$.

happy or non-athletic. Any one of these two thousand forms can be at once tested as regards its validity by the above 'Rule for the Inconsistency.'

CHRISTINE LADD FRANKLIN.

AMERICAN CHEMICAL SOCIETY.

THE American Chemical Society will celebrate the 25th anniversary of its foundation in the city of New York, on Friday and Saturday, April 12th and 13th. Prominent chemists from every portion of the United States are expected to participate in the festivities which include a presentation of the history and achievements of the Society, its present scope of work and influence and a general review of the progress of chemical science in this country during the past twenty-five years. The present condition of the science of chemistry will also be shown, and the extent of its applications to the various industries.

The American Chemical Society is an outgrowth of a meeting of American chemists held in Northumberland, Penn., August 1, 1874, to celebrate the centennial of the discovery of oxygen by Sir Joseph Priestley. The large body of eminent chemists there assembled believed that the time had come for the formation of a permanent society, which should be representative of American chemists and their work, as the foreign chemical societies are of the chemists of their respective countries.

It was not until the year 1876, however, that this idea took definite form in the establishment of the American Chemical Society. In the early part of that year the Society was organized, and in 1877 it was incorporated under the laws of the State of New York.

The first president was that distinguished chemist and physiologist, Dr. John W. Draper, of the City of New York, whose researches in spectrum analysis and pioneer work in the production of the daguerreotype and photograph will never be forgotten.

From the beginning the Society has published regularly a journal of its proceedings, including papers and discussions. Many of the leading chemists of this country have been enrolled in its membership; prominent chemical manufacturers have been among its associates; and not a few of the names of foreign chemists of distinction have been upon its roll, either as active or as honorary members.

About ten years ago very radical changes were effected in the methods and operations of the Society, and the results that have followed have proved the wisdom of the steps thus taken. The important features of the present plan of organization and operation are as follows:

1. Local sections are established in different parts of the country, and the presiding officers of these sections constitute the vice-presidents of the Society.

The following is a list of these local sections up to date: Rhode Island, Cincinnati, New York, Washington, Lehigh Valley, Chicago, Nebraska, North Carolina, Columbus, North Eastern (headquarters in Boston), Philadelphia, Michigan and Kansas City.

2. The general management of the Society is entrusted to a broadly representative council which includes all the past presidents of the Society, one or more representatives from each local section and twelve councilors elected by the membership at large.

3. Two general meetings of the Society are held each year in different localities with a view of increasing interest in the Society and stimulating activity among the chemists in various sections of the country by bringing them into closer acquaintance with one another and into a knowledge of the various interests with which they are connected. The summer meeting is held with that of the American Association for the Advancement of Science, and the win-

ter meeting, which is the annual meeting of the Society, is held at some convenient point during the last week in December. The winter meeting of 1900 was held in Chicago last December. The Society will hold its next summer meeting in Denver, Colorado, August 26 and 27, 1901.

4. The *Journal* of the Society appears on the first of each month during the year. It has been greatly enlarged during the past decade, and every effort is put forth to make it worthy of the Society which it represents. It contains papers read before the various sections of the Society and in its general meetings, together with such abstracts relating to the progress of chemical science and industry, as seem desirable. The estimate in which the *Journal* is held in other countries is shown by the number of articles published in the *Journal* which are fully abstracted or copied entire by foreign periodicals.

The present officers of the Society are: *President*, F. W. Clarke, chief chemist, U. S. Geological Survey, Washington, D. C.; *Vice-Presidents*, the presiding officers of the various sections; *Secretary*, Albert G. Hale, Brooklyn, N. Y.; *Treasurer*, Albert P. Hallock, New York; *Editor*, Edward Hart, Easton, Pa.; *Librarian*, Edward G. Love, New York. The officers of the New York local section are: *Chairman*, Professor C. A. Doremus, College of the City of New York; *Vice-Chairman*, Professor M. T. Bogert, Columbia University; *Secretary* and *Treasurer*, Dr. Durand Woodman.

The total membership of the Society is about 1800, distributed mainly throughout the United States and other portions of the American continent. Some of its members are to be found in Cuba and other islands of the West Indies, others in various European countries, South America and Australia; in fact nearly every nation of the world is represented in its membership.

It is believed that this celebration, with its record of the history and achievements of the Society, and its representation of the character and strength of the organization of American chemists whom it represents, will not only mark an epoch in the progress of the Society itself, but will point the way to higher attainments and greater triumphs in all departments of chemical science and its applications in the New World.

SCIENTIFIC BOOKS.

Sur quelques microorganismes des combustibles fossiles. Par B. RENAULT. One vol., roy. 8vo, pp. 460, with 66 text figs.; atlas, folio, 30 plates with explanation sheets. Extrait du Bulletin de la Société de l'Industrie Minérale. Troisième série, tome XIII., 4e livraison, 1899. Tome XIV., 1re livraison, 1900. Saint-Etienne. 1900.

This is a superb work on a very difficult, but at the same time very important subject both for the geologist and the biologist. It has been many years in process of elaboration, and more than a dozen preliminary papers, dating back as far as 1892, announcing important results as fast as they were reached, have appeared by the same indefatigable investigator, mostly unaided, but also occasionally in association with MM. Bertrand and Roche, who are working somewhat along the same lines.

It is fashionable in our day to extol the wonders of the microscope, especially so since the modern bacteriological investigations began with their momentous practical consequences. The medieval philosophers had not probably any adequate conception of the real meaning of their fine alliterative phrase: *Deus magnus in magnis, maximus in minimis.* Spencer's 'soul of truth in things erroneous' also finds exemplification here, for the 'devils' of which men were once believed to be 'possessed,' in disease, epilepsy, insanity, etc., and which it was sought to 'cast out' by exorcism and prayer, have been shown by the microscope to be real living things—malignant spirits—the invisible germs of disease.

But while it has become clear that these modern revelations have not brought anything new to light, and that these devils were as numer-

ous, as rampant, and as malignant in biblical times as they are to-day, it is only quite recently that the world has gained any conception of their enormous antiquity, and if any one ever supposed that their chief mission was to punish man for his sins, the fact, now made clear by this and kindred investigations, that they existed in equal numbers and in all parts of the world in Tertiary, Secondary, and even Primary time, *i. e.*, ten to fifty millions of years before man made his appearance on the globe is calculated to shake that belief. The microscope, which has so wonderfully illuminated the hidden mysteries of the present and the invisible world in which we live, has now been leveled at the past and brought to bear upon that vast and hoary antiquity of which we could scarcely form a conception even if we were able to express it in terms of our chronology.

In this work M. Renault treats the micro-organisms of past ages under eight different heads, chiefly in the descending order of their occurrence in geologic time, viz., 1st, those found in peat beds of recent origin; 2d, those found in lignite beds, chiefly of Tertiary age; 3d, those found in certain modern bituminous schists; 4th, those found in the so-called boghead formations; 5th, those found in cannel coal; 6th, those found in true coal of the Carboniferous formation; 7th, those found in certain ancient bituminous schists; 8th, those found preserved in flint or silica, chiefly of Carboniferous age.

Peat may be called coal in the making, and consists almost entirely of vegetable matter that has accumulated, often to considerable thickness, where this matter has undergone prolonged maceration. The bulk of it is formed of the remains of the plants that grew on the spot, and which, either from the weight of this constantly increasing superincumbent mass, or from other causes, slowly sink and become buried by successive renewals of the same materials. It takes place in marshes or swamps kept perpetually wet or submerged, under which conditions certain plants long retain their vegetable substance. Many of them, especially dicotyledonous leaves and certain mosses, are thus often preserved permanently, and from their remains much may be learned of the flora of the period at which the peat was formed. Certain seeds are also well adapted to permanent preservation in peat, and it is only recently that extensive investigations of the peat beds of northern Europe have been undertaken by this method. Mr. Leo Lesquereux published in 1844 the results of extensive researches made by him on the peat bogs of the Jura Mountains and Central Europe, and Axel Blytt, Nathorst, Andersson, Sernander, Munthe and others have thoroughly studied those of Scandinavia and other northern regions, while Mr. Clement Reid has in this way successfully worked out the problem of the origin of the British flora. Besides impressions of mosses, and of leaves and stems, and the numerous seeds of spermatophytes found in these beds, the siliceous spicules of many genera and species of diatoms have been detected and systematically treated.

But M. Renault has availed himself of the higher powers of the microscope and has made known to us a large number of other forms of microscopic life. The Bacteriaceæ are found abundantly in the peat of Fragny and Louradou in France, and he has illustrated species of *Bacillus*, *Micrococcus*, *Streptococcus*, *Cladothryx*, etc. The mycelium of numerous fungi also occur.

The principal lignites studied for this monograph have been those of Hérault in the Department of Ain, of Saint-Martin-du-Mont (Ain), of Célas, and Durfort (Gard), and of Sainte-Colombe (Yonne). The first of these, which are Eocene in age, yielded both animal and vegetable forms; Infusoria of the genera *Aspidisca*, *Cinetoconia*, *Ploesconia*, *Vorticellina*, etc., the conidia of fungi referable to the genera *Helminthosporium* and *Macrosporium*, and the mycelium of species of *Morosporium*. Diatoms also occur (*Frustulia*) and Micrococci. The other lignites from localities in France were less fruitful but contained some of the same forms. Besides these, however, M. Renault examined material from Vicenza in Italy and from Coronel in Chili. The latter especially was found to be rich in conidia of the genus *Helminthosporium* and in amœboid forms of the radiate type (*Orbulinella*, *Hedriocystis*, *Clathrulina*).

As an appendix to the treatment of the lignites the author has introduced the results of his investigation of a certain curious fossil combustible from the Lower Carboniferous (Culm) of Tovarkowo and Malevka in Russia, Government of Toula. It consists chiefly of the bark or cuticle of the ancient lepidophyte called *Bothrodendron*, which M. Renault considers distinct from *Lepidodendron*. M. Zeiller has carefully studied this form from the same localities, but the interesting point brought out by Renault is the presence over the whole surface of these paper-coal cuticles of bacteria (*Bacillus*, *Micrococcus*), of which a number of species are figured and described.

The bituminous schists studied for this monograph also proved rich in the remains of extinct microscopic life. Those of Menat, of Oligocene or Aquitanian age, and carrying dicotyledonous leaves of the genera *Planera*, *Liquidambar*, *Cinnamomum*, *Persea*, etc., yielded microscopic fungi (*Helminthosporium*), diatoms (*Amphora*), etc. Those of the Bois d'Asson in the basin of Manosque, of Tongrian age, revealed the presence of Amœboids (*Dactylodiscus*), fungi (*Helminthosporium*, *Macrosporium*, *Sirodesmium*) and diatoms (*Fragilaria*). Some much older schists (Upper Lias) from Anina in Hungary were found to contain fossil algæ resembling the Permian genus *Pila*, also species of fungi of the genera *Mucedites* and *Morosporium*.

The bogheads have formed the object of M. Renault's studies for many years. He has made the beds of Autun, his native city, celebrated by earlier researches. In the present work he has greatly extended his investigations and dealt with similar material from various parts of the world. The bogheads result from the accumulation at the bottom of chiefly Permian lakes of an enormous quantity of microscopic algæ, which were probably gelatinous. In the process of deposition, maceration, and entombment their composition was greatly modified by various influences, among which bacteria played a part. The most important of the algæ forming the bogheads of Autun was the *Pila bibractensis*, named by Bertrand and Renault in 1892. In the present paper the evidence of the agency of bacteria in causing the fermentation of the algoid mass is fully presented and the Micrococci are shown in varied forms.

In specimens of a similar character from the Permian of New South Wales found overlying the coal beds, and probably of Lower Permian age, there occurs another genus of algæ which has been named *Reinschia* for Paul F. Reinsch, a German investigator and pioneer in this branch of research. This same genus recurs in the bogheads of the Transvaal at Ermels. The Torbanite of Torbane Hill, Fifeshire, Scotland, which was the subject of a celebrated lawsuit over the question whether it could be classed as coal, and in which it was at last legally so classed, is treated by M. Renault as virtually a boghead, and yields a species of *Pila* (*P. scotica*). Crushed macrospores of this alga occur along with the globular thalli, and bacteria, although more difficult to find than in other bogheads, have been discovered, consisting of masses of Micrococci. The bogheads of Armadale in Linlithgowshire, Scotland, are formed of various gelatinous algæ, among which another new genus (*Thylax*) is represented.

Among the numerous samples of American cannel coal which I was instrumental in having sent to M. Renault many years ago, and which he has carefully studied, there are some that he classes with the bogheads, especially those from Beaver Dam, Ohio County, Kentucky. These consist chiefly of the remains of a species of *Pila* (*P. kentuckyana*), whose isolated globular thalli form groups of eight or ten and are not disposed in bands. Bacteria are visible in the interior of the thalli.

The coal-bogheads of Alexandrewski, Kourakino and Murajewnja, in Russia, coal basin of Moscow, have a lignitoid appearance, and contain, besides a new species of *Pila* (*P. Karpinskyi*), a new genus, *Cladiscothallus*, with a much branched, discoid thallus. Adhering to the walls and penetrating the interior pulpy mass of *C. Keppeni* is a peculiar *Micrococcus*, which M. Renault has named *M. petrolei*.

The passage from bogheads to cannel coals is a short step, although these last usually belong to the Carboniferous period. They contain, however, to a considerable extent, the same flora

and fauna. In the so-called Bryant cannel of England, M. Renault finds the *Pila scotica*, of Torbane Hill, with macrospores and affected with bacteria. Here occur filaments of a fungus which he calls *Anthracomyces*. The mycella invade the covering of the spores of the algæ. They are very fine but distinct under a high power (1000/1), and susceptible of clear illustration. Other cannels of the Old World present substantially the same features.

M. Renault has carefully studied the specimens of cannel coal sent him from America and the results are interesting. The specimens represented many localities in West Virginia and Kentucky, and the names he gives are: Cannelton and Davis Creek in West Virginia, and Beaver Dam (mentioned above), Little Laurel Creek, Natz Creek, Hunnewell, Georges Branch, Caney Creek, Blackwater Creek, Mercer Station, Magofin County and Buena Vista in Kentucky. Those of Beaver Dam and Little Laurel Creek he classes as bogheads, the rest he regards as true cannels. The Cannelton specimens are filled with spores of ferns and lycopods, the walls of which have Micrococci disseminated through them. Algæ are rare in most of the American material except that of the boghead type, but in that from Davis Creek, classed as cannel, they occur, and belong to the above-mentioned genus *Cladiscothallus*. The species, however, is not the same as that of the Russian bogheads, and M. Renault has done me the honor to name it *C. Wardi*. It is discoid and spread out in a single plane with numerous dichotomous branches. It does not seem to be affected with bacteria. The specimens from Buena Vista, Kentucky, are wholly destitute of algæ.

In the coal basin of Commentry, in central France, which has yielded such a magnificent flora and great numbers of insects, and which I had the pleasure of visiting in September last, there is at the Puits Forêt a combustible mineral substance substantially representing cannel coal. It has yielded to M. Renault's microscope a considerable number of organized bodie, consisting of spores of ferns and Equisetaceæs but no algæ. He also finds the macrospore of *Sphenophyllum* and pollen grains of gymnosperms, wood of *Calamodendron*, and transverse sections of leaves, probably of *Cordaites*. Throughout the mass are everywhere distributed numerous Micrococci, on the surface of the membranes of the spores, and pollen grains, in the fragments of indeterminable vegetable matter and in the general matrix. Similar conditions obtain in certain barren measures at Rive-de Gier in the basin of Saint-Étienne, Upper Loire.

M. Renault treated many specimens of carbonized wood from the coal measures of Zsily, Hungary, Bouble near Saint-Éloi (Puy-de-Dôme) and Decazeville in France, and found them more or less permeated with bacteria (*Micrococcus Carbo*, *Bacillus colletus*, *Cladothryx Martyi*). He also found filaments of saprophytic fungi.

The coprolites and certain fish bones and scales of the bituminous schists of Autun, Igornay and Lally proved a rich field for the microscope, large numbers of Micrococci, bacilli and fungi (*Mucedites*, *Anthracomycetes*) from these sources being illustrated in this work.

A still richer source of fossil microorganisms is the various Paleozoic flints that occur in certain coal basins and other deposits. It was from such that Brongniart described so many remarkable seeds and fruits of Carboniferous plants, chiefly from the basin of Saint-Étienne. They contain all manner of vegetable tissues, and M. Renault finds these permeated with bacteria and fungi. The silica has preserved everything with great exactness and the illustrations of microscopic organisms in this matrix are much clearer than those from the fossil combustibles. Some of these are older than the coal measures and are found in the Culm and even in the Devonian, as those of the Cypridine schists of Saalsfeld, in which silicified remains of *Cordaioxylon* are affected by a *Micrococcus* (*M. devonicus*). At Estnost, near Autun, the roots of a species of *Lepidodendron* (*L. estnostense*) have buried in their parenchymatous tissue the eggs of an insect or arthropod, which has been named *Arthroon Rochei*.

Further details cannot be given here, but this notice should not be concluded without calling attention to the geological and even economic value of the work. It goes far toward furnishing the solution of many of the

most difficult problems that the study of the origin of coal and other fossil combustibles presents. It should be carefully studied from that point of view.

Neither should the fact be left unstated that in these difficult and recondite researches M. Renault has advanced theories that are not accepted by all, but the criticism and, if need be, the disproof of which belongs to those who are engaged in the same line of investigation and are equipped for such a task.

LESTER F. WARD.

The Elements of Astronomy. By Sir ROBERT BALL. New York, The Macmillan Company. 1900. 183 pages, 23 figs., and 11 full-page plates. Price, 80 cents.

This little book contains a clearly written account of astronomical subjects, adapted to the needs of beginners. After a brief historical introduction and an explanation of the apparent diurnal motion of the celestial sphere, the Sun, as the heavenly body most important to us and most interesting to the novice, is rightly placed first. If any change were to be suggested here, it would be that this topic should receive fuller treatment and more complete illustration. The author's admirable *Story of the Sun*, which is both accurate and interesting, fits him to present this subject advantageously.

It is to be regretted that the eclipse photographs, which are supposed to show solar prominences and the corona, are so badly reproduced as to be almost worthless; and while the introduction of photographic illustrations directly from nature is very desirable, the public has a right to demand that such pictures in a work of more than ephemeral value shall have that degree of precision which modern art processes are able to give. In case the publishers have not at their command facilities for reproducing pictures with delicate details, a well-executed engraving, correctly interpreting such details, is to be preferred to a poor photograph. Good illustrations are given of the Full Moon, Saturn, Jupiter, the Dumbbell Nebula, and clusters in Hercules and in Perseus.

Since one of the objects of scientific study is to inculcate conceptions of precision, the indiscriminate grouping of stars of several orders of magnitude from Sirius (—1.5 mag.) to Capella (0 mag.) under the title 'first magnitude' stars (p. 7–8) is to be deprecated.

In an edition prepared for American readers it might be well, if a common name is to be used, to substitute The Dipper for The Plough in designating a part of Ursa Major which 'in this country' is familiarly known by the former title.

A similar remark applies to the statement on p. 57 that midsummer twilight in 'our' latitudes lasts all through the night, which lacks generality and is inappropriate in a science whose chief merit as a discipline for young readers is that it tends to broaden our conceptions by wiping out local distinctions.

The author's familiarity with mathematical processes gives him a firm grasp on everything of a geometrical nature, but also a beautiful simplicity and directness in his demonstrations, which does not always follow from individual comprehension. The chapter on the diurnal motion is simplified by the omission of some details which would have to be considered in a more extended treatise; but one cannot omit to note that quite apart from this, the method and language of the demonstration are uncommonly clear and convincing.

It is natural that we should expect the same clearness in those subjects which Sir Robert Ball has made peculiarly his own—such as precession and the tides—and the reader will not be disappointed here. The history of the Earth-Moon system and the chapter on gravitation will be found especially interesting.

It is permissible, even in an elementary treatise, that an author should develop somewhat those parts of the subject on which he is an authority and where he can speak better than any one else; and since a selection has to be made in a small work like this, it is just as well that the illustrations chosen should be those most familiar to the author; but there are other inequalities which cannot be commended.

A considerable space is devoted to an argument as to the exceedingly high surface-temperature of Jupiter, which is purely speculative,

and by no means as probable as the author maintains. The oceans of boiling water remind one of the cataclysmal hypotheses in vogue in earlier geological speculation, and raise the question whether here also there may not be a less sensational interpretation of facts.

The lunar temperature, on the other hand, in regard to which we have some knowledge derived from quantitative measurements, is not so much as mentioned in the book.

Barnard's fifth satellite of Jupiter is given a whole page, which, while commendable as an account of recent astronomical progress, seems to show a lack of perspective, since only an equal space is devoted to the other four moons with their wonderful harmony. Moreover, in spite of the prominence given to this excessively minute body, the moon, which continues to be called by an anachronism by the Roman numeral I, is alluded to as 'the innermost.'

The 'invisible rays' of the solar spectrum are treated as if they were synonymous with the ultra-violet rays. Over a page is given to this topic, but there is no mention anywhere of the much more extensive infra-red part of the spectrum which comprises rays of greater intensity and of more importance to the earth.

The statement on page 39 that 'we find each one of the multitude of lines in the artificial iron spectrum agreeing to the last degree of precision with the corresponding line in the solar spectrum,' is not in accordance with facts. Along with many wonderful coincidences, there are some notable differences which are of very great importance as furnishing a possible key to further solar mysteries.

The description of the solar corona and of sun-spots in Chapter II. is inadequate, and something more than a bare mention of the fact that there are different classes of stellar spectra is desirable; but the list of shortcomings is not long, and the book is to be commended for its attainment of an exceptional standard of excellence.

F. W. Very.

GENERAL.

Announcement has been made by a committee of American anthropologists, of which Mr. F. W. Hodge, managing editor of the *American Anthropologist*, is secretary, of the proposed publication of a series of more than thirty folk-tales recorded and translated by the late Frank Hamilton Cushing during his long and intimate association with the Zuñi Indian tribe of New Mexico. The price of the work will be $3.50. Information and subscription blanks can be supplied by the Secretary, whose address is Washington, D. C.

The late Professor A. W. Hughes, left in an advanced state of preparation a new volume on practical anatomy. Professor Keith, of the London Hospital College, has undertaken to complete Professor Hughes's work, which will be published by Churchill.

BOOKS RECEIVED.

Experimental Psychology. E. B. Titchener. New York and London, The Macmillan Company. 1901. Volume I. Part 2. Pp. xxxiii + 456. $2.50.

Human Placentation. J. Clarence Webster. Chicago, W. T. Keen & Co. 1901. Pp. 126 and 30 plates.

Studien über die Narkose. E. Overton. Jena, Fischer. 1901. Pp. x + 195. $4.50.

Morphology of Spermatophytes. John M. Coulter and Charles J. Chamberlain. New York, D. Appleton and Company. 1901. Pp. x + 188.

Les problèmes de la vie. Ermanno Giglio-Tos. Turin, Chez l'Auteur. 1900. First Part. Pp. viii + 286. 10 fr.

Clays of New York, their Properties and Uses. Heinrich Ries. Albany, University of the State of New York. 1900. Pp. 593–944.

The Manual of Laboratory Physics. H. M. Torry, and F. H. Pitcher. New York, John Wiley and Sons. London, Chapman and Hall, 1901. Pp ix + 288.

A Select Bibliography of Chemistry. 1492–1897. Section VIII. *Academic Dissertations.* H. Carrington Bolton. Washington, D. C., Smithsonian Institution. 1901. Pp. iv + 534.

SCIENTIFIC JOURNALS AND ARTICLES.

The Journal of the Boston Society of Medical Sciences for December 18, 1900, delayed on account of the plates, has recently been issued. It forms a volume of 180 pages and 16 plates after photomicrographs, devoted to 'A Study of the Bacteriology and Pathology of Diph-

theria,' by W. T. Councilman, F. B. Mallory and R. M. Pearce. The material was derived from 220 fatal cases of diphtheria, and the various regions of the body are treated in detail. An extensive bibliography of recent literature on the subject is appended, the whole forming a most important contribution to our knowledge of diphtheria.

IN *The American Naturalist* for March, W. M. Wheeler and W. H. Long describe 'The Males of some Texan Ecitons' and incidentally tell much of the habits of these ants and of the raids made by them on other species. W. H. Dall discusses 'The Morphology of the Hinge Teeth of Bivalves,' calling attention to the work of Bernard and Steinmann and giving preference to the formula devised by the latter for indicating the arrangement of the teeth and sockets. Harris H. Wilder describes 'The Pharyngo-Œsophageal Lung of Desmognathus,' showing that this species, and inferentially other lungless salamanders, breathes mainly by means of a definitely localized portion of the anterior part of the alimentary canal. J. Arthur Harris presents some 'Notes on the Habits of *Cambarus Immunis* Hagen,' showing that this species, like others of the genus, burrows, and implying that by this means the animals are preserved through the dry months of summer. Albert M. Reese tells of the 'Artificial Incubation of Alligator Eggs' by keeping the eggs in damp *humus* in an incubator at a temperature of 37° C. 'The Colors of Northern Apetalous Flowers' are considered by John H. Lowell, giving a table showing that the great majority are white or dull-colored, and concluding that they are of primitive character and not degraded entomophilous forms. 'The Prehistoric Workshops at Mt. Kinco, Maine,' are treated by C. C. Willoughby, who states that it is evident the products were mainly intended for transportation and to be finished at a distance.

IN the *Plant World* for February William Palmer tells of 'Deforested Cuba' and the manner in which the trees have been destroyed and the soil injured by the continued burning over of the land. Pauline Kaufman describes the 'Orchids in Central Park,' E. M. Williams 'The Masked Tricholoma' and Stewart H. Burnham 'A February Outing in California,' while 'The Discovery of a Plumose Variety of the Ebony Spleenwort' is noted by Francis B. Horton. In the Supplement, 'The Families of Flowering Plants,' Charles Louis Pollard treats of various families of the order Ranales.

THE February number of the *American Geologist* contains an article by S. P. Jones on 'The Geology of the Tallulah Gorge.' The Tallulah River is a tributary of the Chattooga and finally reaches the Savannah in South Carolina. The Grand Chasm of which the paper treats is situated in the crystalline area of Georgia and surrounded by granites, gneisses and schists, supposed to be pre-Cambrian. The principal constituent of the rock is quartz, but small quantities of feldspar and mica are present. The falls are found to have been produced entirely by the river and atmospheric agencies, and it is further found that both falls and gorge are of recent age. It has been shown by certain geologists, with whom the author concurs, that this stream is an example of piracy, having been captured by the Tugaloo from the Chattahoocha river and diverted into the Savannah. In 'Paleontological Speculations,' Mr. L. P. Gratacap gives a few notions derived from an extensive study of collections among which are mentioned those of the American Museum of Natural History. These are studied for the purpose of determining the variations whose accumulated force ushers in new forms in the life series and by whose influence on the organism as a whole a kinetic impulse is established in a new direction. The deductions of Dr. Succo, Professor H. S. Williams, Professor Alpheus Hyatt and others, concerning change of environment of air, water and deep sea, are discussed. The fauna of the different ages and their philogeny, and their development through following ages, are also discussed in an interesting manner. 'The Plan of the Earth and Its Causes,' by J. W. Gregory, follows, and is an interesting discussion of the prevalent theories of the earth's formation, and its growth to its present relations of land, water and air. The discussion is to be continued. Then follows the usual 'Recent Geological Literature,' 'Cata-

logue of Geological Literature' and 'Personal and Scientific News.'

Three new ornithological journals have appeared this year. *American Ornithology*, edited by Mr. C. A. Reed, at Worcester, Mass.; *The Petrel*, edited by Mr. J. W. Martin, at Palestine, Ore., and *The Bittern*, edited by Mr. G. M. Hathorn, at Cedar Rapids, Ia. On the other hand *The Western Ornithologist* has suspended publication.

SOCIETIES AND ACADEMIES.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

AT the meeting of the Academy of Science of St. Louis, of March 4, 1901, the following subjects were presented:

The Corresponding Secretary read a communication from Dr. Amos Sawyer, entitled 'Ethnographic life lines left by a prehistoric race,' the paper being illustrated by sketches, fragmentary human remains and stones, etc., derived from a prehistoric grave examined some ten miles southwest of Hillsboro, Illinois, on the west side of Shoal Creek. In one instance it was stated that a grave consisting of six slabs of limestone contained six skeletons, their thighs flexed upon the abdomen, the legs upon the thighs, their arms placed by their sides, and their heads at either end of the enclosing box and facing east and west. From the limited capacity of the slab-enclosed graves, the writer inferred that the remains had been placed in them after skeletonization, as there was not sufficient room for the number of bodies found unless the muscles had been removed, and it was argued from this that the remains were those of prominent men in the nation.

The Corresponding Secretary read a further communication from Dr. Sawyer, referring to a piece of wood found at a depth of 400 feet below the surface in sinking a shaft for a coal mine. The specimen was said to have occurred in a ten-foot layer of loam filled with the débris of a forest, and the specimen submitted, like others, had been flattened by pressure.

In the discussion which followed the reading of these communications, Mr. Colton Russell said that west of St. Louis, in a number of so-called Indian graves which he had examined, the encasing with rough limestone slabs, mentioned by Dr. Sawyer, had been observed; and Dr. Trelease called attention to the fact that the specimen of wood exhibited, which did not seem to be petrified, belonged to post-glacial times and was perhaps comparable with certain pieces of wood, supposed to be cedar, but not yet carefully studied, which Mr. Hermann, the Sewer Commissioner of St. Louis, had found in company with bones of the early bison in the glacial detritus through which a storm sewer is being excavated at Tower Grove, St. Louis.

A paper by Dr. T. Kodis, 'On the action of the constant current upon animal tissue,' was read by title.

Professor F. E. Nipher stated that he wished to take this occasion to correct some misapprehensions concerning the development of photographic positives. He stated that the effect of development in the light was to make the normal exposure for positives shorter than when they are developed in the dark-room. When for a given illumination of the developing room the exposure has been properly made, the ordinary developer used for negatives may also be used for positives without any restrainer. The restrainer is only needed when the plate to be developed as a positive has been underexposed, or the plate to be developed as a negative has been over-exposed. In both cases it is an approach to the zero condition which calls for the restrainer.

Professor Nipher stated that Mr. Cockayne, of the Heliotype Company, of Boston, had suggested to him the use of potassium ferrocyanide in place of potassium bromide in developing positives, and he had found it to give great brilliancy to the pictures. A Cramer 'Crown' plate exposed in a printing-frame for a couple of minutes at a south window, just out of the direct rays of the sun, under a thin negative or positive, may be developed at the same place. A few drops of a ten-per-cent. solution of the ferro-cyanide may be added, and even as much as one part in twelve of developer has yielded excellent results. The bath has in some cases been wholly made up of the ferro-cyanide solution, the other chemicals being added in dry form. The action of the ferro-cyanide is quite different from that of

bromide in equal strength, although it may be largely a matter of degree.

The bath should not be quite so strongly alkaline as for negatives, in order to get the best results. The best results when pictures are developed in daylight are as fine as can be obtained in the dark room, in the ordinary developing of negatives. Various developers have been tried, but none of them have yielded as good results as hydrochinon.

Mr. G. Pauls laid before the Academy a branch of a small hackberry (*Celtis*) which had become completely covered with the small nodular galls frequently borne in smaller quantities by the hackberry, and called attention to the fact that in this particular case the natural enemies of the gall-forming creatures seemed to have been absent, allowing of their unusual multiplication.

One person was elected to active membership.

WILLIAM TRELEASE,
Recording Secretary.

GEOLOGICAL SOCIETY OF WASHINGTON.

THE 112th meeting was held March 13, 1901, at the Cosmos Club. The following formal communications were presented:

'The Soil Survey of Cecil County, Maryland,' by Mr. C. W. Dorsey. This example of recent soil-mapping, by the Department of Agriculture, was illustrated by a colored map showing the areal distribution of ten classes of soil.

'Discussion of Geologic Units—Formation, Stage and Age,' by Messrs. Bailey Willis, H. S. Williams and others.

Mr. Willis, in introducing the discussion, briefly reviewed past attempts to consistently divide assemblages of stratigraphic rocks into units. He pointed out that a clear distinction exists between division on lithological grounds, and division on paleontological grounds, and that this distinction should not be lost sight of. He believed that the cartographic unit, the formation, should be defined purely on the basis of lithological character. In regard to the terms used for the units of the lithological, faunal and chronological scales in geology, it is highly important that there should be unanimity in usage. Shall we attempt to reconcile and fix the usage of such English substantives as series, formation, system, stage, period, etc., or shall we adopt entirely new terms from some foreign, preferably dead, language, and so avoid tying up well known English words to definite restricted meanings? Several terms from the Sanscrit were given in illustration of this suggestion. Professor H. S. Williams called attention to the fact that a formation, as defined on purely lithological grounds, lacks true unity. Two scales must be used to scientifically describe the formations and faunas which the geologist studies—a structure scale and a time scale. The latter must express definite time values. Such values are presented by (1) the persistence of equilibrium of a particular fauna, (2) the persistence of a particular species, (3) the persistence of a genus, etc. Major J. W. Powell gave his experiences in devising a scientific nomenclature in psychology. He at first endeavored to redefine old words. Readers forgot his definitions and unconsciously used their own in reading his work. He strongly favored the adoption of new terms devoid of all confusing connotations. Mr. Whitman Cross illustrated the difficulties arising when a formation, once defined, is found to thicken and expand into several members in another portion of the field. He was emphatically of the opinion that the evidence of fossils should be freely used in addition to lithological distinctions, whenever such a course will lead to a fuller expression of the structural and historical facts in the geology of a given region.

F. L. RANSOME,
DAVID WHITE,
Secretaries.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 337th regular meeting was held on Saturday evening, March 23d.

Sylvester D. Judd presented a paper on 'Bird Food Problems,' stating that in studying the food of birds as indicated by their stomach contents, one was confronted with the problem of identifying the articles eaten from very small particles. He showed, illustrating his remarks with lantern slides, how the presence of grasshoppers, cut worms, the larvæ of may beetles, earthworms and various plants might be recognized under the microscope from minute

but characteristic portions of these animals or, in the case of the plants, by portions of the seeds or even the form of the starch grains.

F. A. Lucas spoke of 'Some Restorations of Dinosaurs' saying that while a short time ago the Dinosaurs were very imperfectly known, now, through the exploration of our western territory and the systematic methods employed in collecting, we had a very thorough knowledge of these animals and are even able to present restorations of their external appearance. The American Museum of Natural History, of New York, he said, led in this work, and the speaker explained the methods of collecting, showing views of some of the famous quarries and of the specimens as they appeared when prepared and mounted. The matter of restoration was discussed, and the deductions made from the skeletons described and various restorations shown made by Mr. Knight under the direction of Professor Osborn. F. A. LUCAS.

WASHINGTON PHILOSOPHICAL SOCIETY.

THE 532d meeting was held March 16, 1901. The first paper was by Professor Updegraff, of the Naval Observatory, on the 'Errors due to Imperfections on the Pivots of a Theodolite.' After a reference to the well-known theory of elliptical pivots in a V-bearing whose sides are at right angles, the speaker considered the case of an elliptical pivot resting on two cylindrical lugs or ridges; the result of the investigations is that the center of the pivot when rotated does not change its elevation, but has a small movement in azimuth. In the long discussion that followed, Mr. E. G. Fischer, mechanician of the Coast and Geodetic Survey, pointed out that in actual practice the unequal wear of different parts of a pivot, due to unavoidable inequalities in the steel and to use of only a small arc, introduced much greater errors than any due to the original imperfections of manufacture.

Mr. Hussey then gave (by invitation) 'An Informal Account of Recent Work at the Lick Observatory,' showing superb lantern slides of stellar spectra and nebula. The interesting facts which he presented have been made accessible to the public in other ways and need not be repeated here. C. K. WEAD, *Secretary.*

TORREY BOTANICAL CLUB.

THE meeting of January 30, 1901, was held at the Botanical Academy, Bronx Park, New York City.

A paper was presented by E. S. Burgess on the history of *Aster Claytoni*, soon to appear in print. A series of specimens was exhibited showing type and variations, and a range from the Hudson River to Virginia. The first specimen known was collected in the mountains of Virginia by John Clayton, apparently in or before 1754, during his botanical expedition along the James or that to the sources of the Rappahannock. It is No. 767 of the Gronovian herbarium preserved by the British Museum. Comparisons, kindly made by Mr. Edmund G. Baker, of the British Museum, show its identity with plants observed first on Manhattan Island at Inwood by E. S. Burgess in 1896, and kept under observation since for study of development. The description of No. 767, written by Clayton and Gronovius, and published in the 'Flora Virginica,' Part III, in 1762, without a specific name, long remained without reference to any of our known native species, Forster's reference in 1771 to *Aster macrophyllus* proving untenable. In reestablishing the species in the 'Illustrated Flora,' in 1898, under the name *Aster Claytoni*, it was intended to pay this tardy tribute to the memory of its discoverer, John Clayton, rightly styled by Collinson as at that period, 1764, 'the greatest botanist of America.' The species seems particularly frequent in the lower Hudson region, where it had, however, been hitherto confused with its smoother and more forking ally, *Aster divaricatus*.

At the meeting of February 13, 1901, at the College of Pharmacy, in New York City, Dr. J. K. Small presented a paper entitled, 'Notes on Some Species of *Rudbeckia*,' exhibiting a series of specimens of *Rudbeckia*, illustrating groups typified by *R. hirta*, *R. triloba*, *R. laciniata*, etc. Numerous critical characters depending on style-tips, form, serration or lobation of leaves, etc., were discussed. About 25 species occur east of the Rockies, 3 native to our own vicinity. All evidence shows *Rudbeckia hirta* to be an introduced plant in the northeastern states, perhaps from Maryland northward. Dr. Underwood remarked that *R. hirta* seemed to be first

introduced into Central New York about 1864. Dr. Rusby referred to its rarity within his memory in the vicinity of New York City, and to the recently discovered medical value of the related genus *Echinacea*. Dr. Britton called attention to the supposed variants of *R. hirta* with parti-colored rays, as suggested by plants from near Philadelphia and from Staten Island.

Dr. Britton presented the subject of the relationship of our woodland species of *Circæa*, *C. Lutetiana* being the representative near New York City, and extending widely around the world. The characteristic bristles of the fruit fail to appear in a remarkable specimen from Ohio which was exhibited. *C. intermedia* of Central Europe was also discussed in its relations to the foregoing.

The third paper, also by Dr. Britton, was upon *Antennaria*. Dr. Britton exhibited a series of specimens of *Antennaria neodioica* Greene, a species which seems to be easily distinguished from the others of eastern North America by its spatulate basal leaves, distinctly mucronate, tapering rather abruptly from well above the middle into a long narrow base, which, however, can scarcely be called a petiole. He showed specimens of the plant collected in company with Professor Greene at Bushkill, Penn., on the Club's Field Meeting, May 30, 1897, at which time Professor Greene first insisted on its specific difference from *A. plantaginifolia* with which it grew. The series included authentic specimens of *Antennaria rupicola* Fernald, which differs only from the typical specimens in the yellowish involucre, and slightly less abruptly tapering leaves, collected by Mr. Fernald at Island Falls, Aroostook Co., Maine, a character which can hardly be maintained for specific distinctness; also specimens of *A. neodioica attenuata* Fernald, which differs from the type in its slightly more acuminate inner involucral bracts and relatively broader leaves, and is identical with *A. alsinoides* Greene, original specimens of which were also included in the exhibit; also of *A. neodioica grandis* Fernald, which differs from the latter only in size. He concluded that the series represented only one species, *A. neodioica.*

Dr. Rusby referred to the similar variability of Andean species of *Gnaphalium* as seen by himself and other botanists in Bolivia.

Dr. Howe discussed the relationship of *Riccia Beyrichiana*, the hepatic which he had considered to be probably identical with one discovered by Mr. R. Harper near Athens, Georgia, last summer. The loan of the type-specimen from Vienna now shows that the two are wholly distinct, Mr. Harper's plant representing a new species, soon to be described in the *Bulletin*. *Ricca Beyrichiana* seems, therefore, to be still known only from the original collection of 1833.

Edward S. Burgess,
Secretary.

SCIENCE CLUB OF NORTHWESTERN UNIVERSITY.

The last meeting of the Science Club of Northwestern University was held on March 1st. Professor A. R. Cook addressed the Club on 'Minerals of the Chicago Area.' The region, though containing no stores of precious metals, or gems, and though not mentioned in lists of mineral localities, has minerals enough; first, to represent five out of the eight classes into which the mineral kingdom may be divided; second, to illustrate the chemical, crystallographic, optical and other physical properties of minerals, and third, to show the chief methods of investigation.

Thus far forty-eight minerals have been found and studied. One fourth of them occur in the underlying Niagara limestone. They are of such character as the geological history of the region would lead us to expect.

Those occurring in the Niagara are most important since they most properly represent this region. They are sulfur, galena, sphalerite, pyrite, marcasite, quartz, limonite, calcite, dolomite, siderite, melanterite, petroleum, gas, asphalt.

The sulfur occurs in crumbling rounded masses in the center of the decomposing marcasite. Galena and sphalerite are in crystalline masses with occasional crystal planes developed, showing characteristic cleavage, and contained both in limestome and in quartz.

Pyrite is most common when the containing limestone most nearly approaches the purity of calcite. The surprising condition is the great abundance of the orthorhombic form of the iron sulfid. Pyrite is rare but marcasite occurs in

extensive beds where it has been sorted out by hydraulic action as in the Des Plaines valley or on the lake shore. A bed several feet wide extended along the water's edge for two hundred feet where the lake was encroaching upon the shore. The marcasite soon disappears upon exposure; it is of such occurrence in the region as to contribute to our knowledge of the species.

Quartz occurs in abundance in both phanerocrystalline and cryptocrystalline varieties. Good scalenohedrons of calcite are found at Stony Island imbedded in asphalt.

The asphalt and maltha which are usually disseminated through the Niagara limestone of the region occur quite pure in cavities formed by the dissolution of fossil cœlenterates, echinoderms and mollusks in the strata at Stony Island.

The average of four analyses showed 15% mineral matter, 82% organic matter soluble in CS_2, and 2% of organic non-bituminous matter.

The asphalt contains 25% petrolene and 75% asphaltine.

HORACE M. SNYDER,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE APPLICATION OF PRECEDENCE OF PLACE IN NOMENCLATURE.

IT has occasionally happened in descriptive botany and zoology that two or more different names have been published by an author for the same species in the same work, even on the same printed page; in most such cases this has occurred by reason of the author regarding differing forms of the same organism as specifically different, which by subsequent observation has proved to be erroneous. The principle of now using the first in position of these two or more names as the true one, has obtained wide recognition, and is a simple and convenient method to reach this result.

There are also a few cases where the same thing has occurred with generic names, that is to say, by different generic names being published in the same work for groups of species which subsequent study has indicated to be more satisfactorily regarded as within the natural limitations of a single genus, and here precedence of place has also been invoked to determine which appellation the combined genera should bear. Here, as in the case of species, it is only a question of determining which of one or more names for the same things is the one to be employed.

The principle has been referred to as 'priority of place,' and perhaps not improperly, but it is quite a different matter from priority in time of publication, though in its application operating in the same manner to determine which of two or more rival names is to be used. It finds its most explicit presentation in the rules for nomenclature adopted by the botanists of the American Association for the Advancement of Science, at the Madison meeting in 1893, where it is thus stated:

In determining the name of a genus or species to which two or more names have been given by an author in the same volume or on the same page of a volume, precedence shall decide.

More recently it has been proposed by some botanists, as had previously been done by some zoologists, to fix the type species of every genus originally published with more than one species, by selecting for this the species which stands first on the page at the place of publication, and it has been contended that this is a logical outcome of the principle, thus giving it a widely different application from that contemplated in the rule cited above, by making it apply not to the determination of equivalent names for the same thing but to non-equivalent names for different things, a wholly different proposition. Inasmuch as a great many genera have at their first publication been made to include more than one species, and in a large number of instances some of these, often the first in position, have been used by subsequent authors as the types of additional genera, this latter-day proposition affects an enormously greater number of cases than those which fall properly under the operation of the rule.

It is, therefore, clear that there is nothing logical in the proposed extension of the principle. This would, of course, operate as an artificial short-cut in determining generic types, except in the cases where the first species named is not definitely understood, but in many instances it would lose the historic type

altogether, and in others it would render useless for nomenclatural purposes much original investigation through which genera have been definitely established. Unless rigidly restricted in such a way as to avoid these defects it would be impracticable and undesirable.

N. L. BRITTON.

CLAYTON'S ECLIPSE CYCLONE AND THE DIURNAL CYCLONES.

MR. H. H. CLAYTON, of the Blue Hill Meteorological Observatory, Mass., has published an account of his discussion of certain meteorological observations made during the eclipse of May 28, 1900, in the *Proceedings of the American Academy of Arts and Sciences*, Vol. XXXVI., No. 16, January, 1901; and the full report in Vol. XLIII., Part 1, of the *Ann. Har. Coll. Obs'y*, 1901. Mr. R. DeC. Ward reviews these papers in SCIENCE of March 1, 1901, and says, "Clayton has gone far ahead of all previous investigations of the phenomena of eclipse meteorology. The low temperature, the circulation of winds and the form of the pressure curve all proclaim the development by the eclipse of a *cold-air* cyclone, as described by Ferrel; * * * The fall of temperature due to the occurrence of night must also produce, or tend to produce, a cold-air cyclone. Since the heat of day produces, or tends to produce, a warm-air cyclone; * * * These causes must, in the opinion of the author, produce entirely, or in part, the well-known double diurnal period in air pressure; * * * His explanation of the diurnal variation of the barometer seems to have in it many evidences of being the best yet offered to account for this puzzling phenomenon."

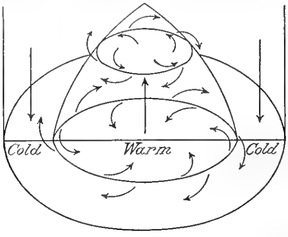
I suspect that Mr. Clayton and Mr. Ward have an incorrect conception of Ferrel's cold-center cyclone, or else they could hardly have written about it the remarks contained in these papers. The subject is rather complex, but I hope, very briefly, to indicate the leading discrepancies for the benefit of others who think that the problem of the diurnal variation of the barometer can be solved along these lines.

1. *Some Minor Errors.*—Clayton's Formula, page 8, $\tan\,\theta = \frac{\Sigma\,(\sin o)\,v}{\Sigma\,(\cos o)\,v}$ should be written $\tan\,\theta = \frac{\Sigma\,v.\,\sin o}{\Sigma\,v.\,\cos o}$, where o is the azimuth of the observed wind, and θ that of the mean or prevailing wind; but this function between θ and o is incomplete and it often gives an incorrect result. In the diagram the wrong diagonal is drawn, and this introduces confusion into the exposition of the formulæ for determining C, used in $\theta^1 = \theta \pm 180 \pm C$, where θ^1 is the azimuth of the eclipse wind which is required. As the eclipse wind for Washington, Ga., Wadesboro, N. C., and Blue Hill were computed by these formulæ, the results must be imperfect. The observations were themselves not very satisfactory, as is inferred from the account of them.

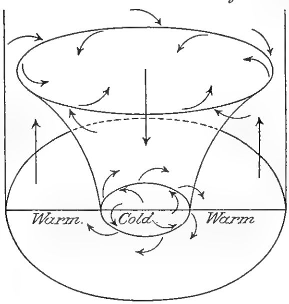
2. *The Cold-Center Cyclone.*—Ferrel's account of the cold-center cyclone is found in the Report of the U. S. Coast Survey, 1877, Appendix No. 20, page 187; in the Report of the Chief Signal Officer, 1885, Appendix 71, page 257; and in other places. Also there are some general remarks on the subject in the International Cloud Report, 1898–99, page 615. The accompanying diagrams show the circulation in the warm-center and cold-center cyclones, respectively, and the distributions of pressure characteristic of them; these must serve for further explanations in this place. In order that there may be no doubt about Ferrel's idea of the cold-center cyclone, I quote from the Report of the Chief Signal Officer, page 257, "The gyrations at the earth's surface must be in the same direction as in the case of ordinary cyclones; * * * The interchanging motion is from the center below and toward it above." Report of Coast Survey, page 188, "The maximum barometric pressure is where the gyrations are reversed; * * * The pressure is a minimum at the center and a maximum at the edge" of the cold-center cyclone, at all altitudes, meaning by edge the locus where the gyrations reverse direction.

Ferrel illustrates the cold-center cyclone in these two reports, also in his popular treatise on the winds, pages 246–247, 337–342, by comparing it with the general circulation over a hemisphere of the earth, where the poles are cold and the tropics warm, and states that the circulation is the same in each. That is, the air descends at the pole, flows south and *east*

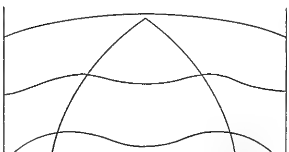
(not west) to latitude 30°, thence south and *west* (not east) to the equator, in which region it ascends, etc. Thus, page 337, "This vertical circulation, as in the case of the ordinary cyclone, gives rise to a cyclonic motion in the interior (that is, to the place where the gyration reverses from $+v$ to $-v$) and an anti-cyclonic in the exterior part." Cyclonic rotation is against the hands of a watch, looking down upon it, and anticyclonic is with the hands, so that in warm and in cold-center cyclones the rotation is cyclonic near the center, and anticyclonic beyond a certain circle of reversal. In the warm-center cyclone the motion is ascending and inward near the surface in the interior and descending in the exterior; in the cold-center cyclone these motions are reversed, but the *direction of rotation about the pole is not changed.* Ferrel's formulæ, diagrams, and discussions agree in this throughout his works; indeed, there could be no other interpretation of them on mechanical principles. He says, C. S. O., page 203, "Such areas of high barometer (referring to the high pressure area produced by the overlapping of two adjacent cyclones) are usually called anticyclones, and the air does in some manner move around them in a direction contrary to that of a cyclone, but this does not arise from a central area of greater cold, for it has been shown that such a condition *would give rise to a cyclone and not to an anticyclone*, and that the latter would be entirely at variance with fundamental and well established principles of mechanics."



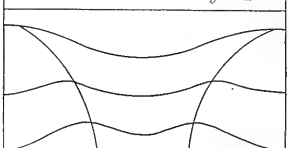
Circulation in warm Center Cyclone.



Circulation in cold Center Cyclone



Isobars in warm Center Cyclone



Isobars in cold Center Cyclone.

Isobars in Clayton's "Eclipse Cyclone"

When the temperature gradients are very steep and there is much friction on the surface, a small secondary maximum pressure may develop in the center of the cold-center cyclone. In the case of the eclipse the temperature gradients were feeble, and the wind velocity v small, upon which the friction-force $= k.v$ depends, so that it could not happen under the circumstances of the eclipse phenomenon.

Now by comparing Clayton's diagram, Fig. 5, Plate II., for the wind direction, we find a *true anticyclonic* configuration at the center, and this rotates in the opposite direction to that required in the cold-center cyclone; if wind stream lines were to be drawn from the center outward at *right angles* to those contained in the Clayton diagram, we should then obtain a cold-center cyclonic circulation,

but this is just the opposite of the result of the eclipse observations. Furthermore, Plate III., 'Pressure in Eclipses,' shows us the variations in pressure as observed, and these are reproduced in the lowest section of the adjacent diagram. It is seen that the pressure in the eclipse is *reversed throughout its length to that required in the cold-center cyclone.* The Weather Bureau observations at sixty-five stations confirm the Clayton distribution of pressure, but the conclusion is also unavoidable that we are not dealing with a cold-center cyclonic circulation. My further remarks on this subject will be found in the forthcoming report by the Weather Bureau.

3. *The Semidiurnal Cyclones.*—Even if the analogue between the eclipse circulation and that assumed to exist in the nocturnal circulation were not hopelessly in error, there are yet other difficulties to be considered, even supposing the cooled hemisphere of the atmosphere were to produce something like a cold-center cyclone and the heated hemisphere a warm-center cyclone. (*a*) The vertical circulation in the cold-center and in the warm-center cyclones are in *opposite directions* to one another at the belt of highest pressure, so that they would tend to destroy each other, rather than build up any high pressure belt such as the diurnal pressures require. (*b*) If there is a cyclonic circulation of any kind, the conditions demand that the pressure be distributed quite symmetrically on all sides of the center in order to maintain a true gyratory motion; but in the diurnal barometric pressure there are found to be simply two peculiar waves extending from pole to pole, which do not in the least form such a symmetrically distributed pressure about a center. Compare Int'l Cloud Report, Chart 44. (*c*) According to Clayton, Plate IV., the high pressures at the surface shift about 90° in the higher strata. But so far as I know, the only data bearing upon this point are contained in the Blue Hill hourly cloud observations, and these show that the *same diurnal circulation* exists in the atmosphere from the surface to the cirrus level. However, this may be a doubtful point and I will not press its accuracy. Compare Int'l Cloud Report, Chart 45.

I have generally found myself in accord with Mr. Clayton's published results, and I am sorry to be obliged to dissent from his interpretation of the eclipse observations in this case. The variations of pressure in the eclipse are not larger than 0.01 inch of mercury, and the velocity of the eclipse wind is only 2 or 3 miles; but it would seem hardly credible in the face of these facts that this small atmospheric disturbance should set up any true cyclonic circulation over an area 5,000 miles in extent, as is claimed in the report under consideration.

Frank H. Bigelow.

Washington, D. C., March 20, 1901.

THE REVERSAL OF THE PHOTOGRAPHIC IMAGE BY CONTINUED ACTION OF LIGHT.

The remarkable results described by Professor Francis E. Nipher, in developing photographic plates in daylight, bring to mind some of the earlier experiments upon the reversal of the photographic image. It has long been known that under particular conditions of over-exposure in the camera a positive, instead of a negative, is produced by ordinary development. This result has been repeatedly observed by amateurs, much to their astonishment and mystification.

The present writer has several times attempted to bring about the effect by prolonged exposure in the camera, but without success. The necessary conditions not being known, the result is accidental and uncertain. The idea of giving a supplementary exposure of the plate in broad daylight did not suggest itself; indeed, it is not one that would spontaneously commend itself to a photographer. All his previous training and experience is opposed to it on general principles.

Nevertheless, it is not entirely new. Herschell, in the year 1839 or 1840, did very much the same thing. He observed reversals of photographic action, and so did Draper on strips of sensitized paper with which he was studying the chemical action of the sun's light in Virginia, and photographing the spectrum in ephemeral colors. This subject was referred to quite recently in an article by the present writer, entitled, 'Tithonic Rays and Early

Photographs in Color,' published in the *International Annual of Anthony's Photographic Bulletin*, XIII. (1901), 107. At that time and also many years later, the effects observed were attributed to an antagonistic action between light radiations from different parts of the solar spectrum.

Many years ago, when collodion wet plates were mostly in vogue, there was considerable discussion among photographers of the effect of exposing sensitized plates to diffused daylight, either before, during or after the usual exposure in the camera. Some claimed that such a supplementary exposure made the plates more sensitive, so that the camera time was materially shortened. The admission of a little diffused light through a hole in the camera was claimed to be advantageous in the same way. Others questioned the utility of the practice and the question was finally dropped and forgotten.

There may have been a basis of truth in the contention of those who advocated the supplementary exposure, but it was not satisfactorily established at the time. There is less reason for skepticism now than there was in those days. Although not exactly in line with Professor Nipher's work, the subject bears a close relation to it.

More directly connected with the recent observations is the work of M. J. Jansen, at Meudon, in the year 1880, when he was engaged in studying the solar radiations. In his original communication to the French Academy, published in *Comptes Rendus* of that year, he used the following language descriptive of his work: "I have the honor to inform the Academy of the discovery of a fact to which I have been led by my studies in the analysis of the light of the sun and of its photographic images.

"This fact consists in this, that the photographic images may be reversed, and pass from negative to positive by the prolonged action of the light which has produced them."

Ordinarily the exposures for negatives were about one-thousandth of a second, or when bromide plates were used, one ten-thousandth. But when the exposures were prolonged to half a second or a full second—increased 10,000 or 20,000 times—he obtained a positive picture instead of a negative.

The investigations were continued and in a second communication to the Academy, also published in *Comptes Rendus* (Vol. XCI.), he made known some remarkable results.

By varying the times of exposure he found an intermediate condition of the plate at which neither a positive nor a negative could be developed. His conclusions may be briefly summarized here. With exposures of increasing duration he discovered six different successive conditions of the sensitive plate. These developed in order as follows:

1. A negative. The ordinary negative.
2. A first neutral condition which blackened uniformly in the developer.
3. A positive.
4. A second neutral condition, opposed to the first, which became uniformly lighter in the developer.
5. A second negative, similar to the first but differing by the enormous amount of light required to produce it.
6. A third neutral condition, in which the negative of the second order had disappeared and was replaced by a sombre, uniform tint.

These facts were established with different kinds of plates—tannin plates, gelatin-bromide and others.

It is scarcely necessary to indicate the bearing of these observations on the results of Professor Nipher's experiments. Does not the fourth condition suggest that if a plate in that stage were developed in a lighted room it would show a negative picture?

About the time of these observations of Jansen, considerable attention was being directed to the subject of reversals of the photographic image; but most of the literature deals with theories in explanation of the facts. Although the discussion was sufficiently instructive and interesting, it does not seem to me that we are sufficiently acquainted with the chemical effects of light in photography to warrant much chemical theorizing in this particular field.

ROMYN HITCHCOCK.

NEW YORK, March 18, 1901.

SHORTER ARTICLES.

A NEW OCCURRENCE OF CASSITERITE IN ALASKA.*

During the past season while making a hasty reconnaissance of the York gold field of Alaska, my attention was called to some auriferous gravels which carry a large percentage of stream tin. This stream tin is found in considerable quantities on Buhner Creek, which enters the Anakovik River from the west about three miles from Behring Sea. The occurrence is perhaps best located by stating that it lies some ten miles east of Cape Prince of Wales and hence very near the northwestern extremity of the continent. On Buhner Creek some two to three feet of gravel overlie the bed rock which consists of arenaceous schists which are often graphitic, together with some graphitic slates. The bed rock is much jointed, the schists being broken up into pencil-shaped fragments. They strike nearly at right angles to the course of the stream and offer natural riffles for the concentration of heavier material. A hasty reconnaissance of the drainage basin of this stream, which includes not more than a square mile of area, showed the same series of rocks throughout its extent. At a few localities some deeply weathered dark green intrusives were found, which, on examination by the microscope, were found to consist almost entirely of secondary minerals. In some cases, however, a little plagioclase was still unaltered and a suggestion of ophitic structure remained, so that these are probably of a diabase character. The slates and schists are everywhere penetrated by small veins consisting usually of quartz with some calcite and frequently carrying pyrite and sometimes gold. These veins are very irregular, often widening out to form blebs and again contracting so as not to be easily traceable.

The stream tin is concentrated on the bed rock with other heavy minerals and was found by the miners in the sluice boxes. A sample of the concentrate in one of the sluice boxes was examined by Mr. Arthur J. Collier and yielded the following minerals: cassiterite, magnetite, ilmenite, limonite, pyrite, fluorite, garnets and gold. The determination of percentage by weight was as follows: ninety-five per cent. tin-stone, five per cent. magnetite; other minerals five per cent. The cassiterite occurs in grains and pebbles, from those microscopic in size to those half an inch in diameter; they have sub-rounded and rounded forms. In some cases there is a suggestion of pyramidal and prismatic crystal forms. The cassiterite varies from a light brown color to a lustrous black.

A second locality of this mineral was found on the Anakovik River half a mile below the mouth of Buhner Creek. Here the cassiterite is also found with the concentrates from the sluice boxes of miners. I observed one specimen from this locality which was some two inches in diameter.

During the hasty reconnaissance no acid intrusives nor pegmatite veins were found in the drainage basin. The nearest known granitic rocks are in the biotite granite mass which forms the promontory of the Cape Prince of Wales. It is hoped during the coming season that more detailed work in this region will throw further light on these interesting deposits.

NOTES ON PARASITES — 56: ECHINOSTOMUM BURSICOLA LOOSS AND E. CLOACINUM BRAUN, FROM A NOMENCLATURAL STANDPOINT.

Professor Max Braun * has recently proposed the name *Echinostomum cloacinum* as a substitute for *Distomum bursicola* Creplin, upon placing this species in the genus *Echinostoma.* Braun's reason for changing the specific name is that there is already an *Echinostomum bursicola* Looss, 1899, and he assumes that this invalidates the specific name *bursicola* Creplin, 1837.

In this decision, Braun has fallen into error. It is not *bursicola* 1899 which invalidates *bursicola* 1837, but the latter invalidates the former. Hence *E. cloacinum* Braun, 1901, must fall as a

* 1901.—Ueber einige Trematoden der Creplins'chen Helminthensammlung. Cent. f. Bakt. Paras. u. Infek., XXIX., 1 Abt., No. 6, Feb. 25, 258–260.

synonym of *Echinostoma bursicola* (Creplin, 1837) nec Looss, 1899.

In order to straighten out the synonymy immediately, I here propose the name *Echinostoma africanum*, nomen novum, as substitute for *E. bursicola* Looss, 1899, nec (Creplin, 1837) Stiles, 1901.

BUREAU OF ANIMAL INDUSTRY.

AMATEURISM AND MENTAL INERTIA IN PUBLIC SERVICE.

IN a striking presentation of the results of 'Official Obstruction of Electric Progress' in Great Britain, by Professor J. A. Fleming, in *The Nineteenth Century* for February, that distinguished writer and scientific authority describes the outcome of the existing system of public service in Great Britain in the departments of telegraphy and telephony and the relative retrogression of that nation in all departments of electrical engineering. "In reviewing the nationality of those who have thus helped to make the electric current the humble servant of mankind, it is impossible not to be struck with the fact that British names do not preponderate."

In pure scientific research, Great Britain has held her own; in detailed improvements and minor advances she has not been backward; but has made no fundamental invention or discovery, except, perhaps, those 'of Lord Kelvin in submarine telegraphy, of Mr. Swan in electric lighting and of Professor Hughes in telephony'; practically all first-rate novelties have originated in other countries, for a generation past. The reason is attributed largely to the fact that in 1870, just at the dawn of the period of electrical activity, the Government set itself up in business as an electrician and proceeded to create a gigantic Government monopoly in one large department of electrical invention which has exercised a most undoubted control over the supply and demand for invention in a wide area of electrical work. It invested £10,000,000 in telegraph purchases, made the business a monopoly, and thus smothered invention through that monopoly and an always characteristic governmental inertia, an inertia, misnamed conservatism, always to be observed where, as in such cases, the alertness in effecting improvement and in competition which characterizes private business for private profit is absent. This 'conservatism' is seen in all departments of the public service and is liable to produce serious retrogression in every national enterprise and in all countries. It was also illustrated, according to Professor Fleming, in the case of the telephone. No sooner was this extraordinary invention made practicable than the British Government, even without explicit authority of law, compelled its proprietors and promoters in that country to pay tribute to the Postal Department, and to-day, while the postal service and the telephone are conducted at a loss, the telephone is made to contribute, without substantial return to its proprietors, the amount of £130,000 to the profit side of the postal service ledger; while the official service of the telegraph, too largely amateur, brings in a loss of over £220,000. The National Telephone Co. has paid into the treasury of the postal service over a million of pounds, since its capitulation to that service, as a 'tax on a new industry barely twenty years old.' The higher tribunals have never confirmed this act of piracy, as it is considered by the members of the company.

As this writer states: "The whole behavior of the post-office towards private enterprise in telephony in the last twenty years has been marked by inconsistency, inaptitude and want of prevision." The business which it itself conducts is a source of enormous loss; that which it simply taxes and burdens pays a sufficient profit to bear this invidious taxation, to which other industries are not subjected. It is a fair presumption that, were the telephone managed directly by the Government, it would exhibit a lack of thrift and efficiency similar to that characterizing the postal and the telegraph business. Meanwhile, also, the postal service deliberately impedes the telephone management in its endeavors to secure rights of way, and compels it to charge the public a much higher tariff than would be fair and practicable were it not discriminated against in taxation, and thus its range is restricted as well as its value to those who are able to secure its service. In all ways the hope of reward which is the

great stimulus of the inventor and of the promoter of new improvements is repressed. The conclusion of the writer of the paper referred to is: "The most effective method of afflicting any department of applied science with creeping paralysis is to constitute it a government monopoly."

While the State electricians would probably declare that they are 'ever on the outlook for new things,' the record is shown to invalidate that claim, at least to the extent of showing that the new things have come vastly more certainly and promptly to the private management. Inventions have been extensively exploited by private means and private companies far in advance of any governmental action, and the inventor proverbially dreads the necessity of going with his plans to a governmental department in all countries and whatever his field of work. Even the inventor of the apparatus of war has his bitter experiences with the official, and the history of the work of Maxim and of Broadwell still earlier, among our own great inventors, may be added to the examples quoted by Fleming, of Morse, of Trowbridge, of Marconi and others. Government officials do not always cordially and sincerely strike hands with the inventor, even where competent to appreciate his work, and it is too often the fact that they prefer to hold him at arm's length until one of their own caste or a partner in invention can find ways of evading his claims and of reaping the harvest he has sown.

"The State officials guard a monopoly. It is in their power to take or reject improvements. They set the pace in one large department of electrical invention and it cannot be forced." As Mr. Edison said to Professor Fleming when the latter explained the nature of these governmental impediments of progress in electrical development: 'Why! They've throttled it!'

In electric traction the same difficulties are interposed, in appropriate ways, by the official brakesmen. Great Britain has to-day about 400 miles of track; the United States has 12,000 or more. In that country any local government may take away the property of any tramway within its limits, at the appraised value of its real property, after twenty years of service. This provision of law has crippled the enterprise. 'To tell an investor in tramway stocks that, after passing through a long non dividend-paying period, he has then the prospect of having his property taken from him at a breaking-up price, and perhaps half his property confiscated,' is to warn him not to invest. Thus the business languishes and the builder of even the comparatively promising railways about London must come to the United States for all his material and machinery.

Scientific education is looked upon as one element of the needed radical reform. But "What is required is not abundant mediocrity, but a fully sufficient opportunity of training those who will be captains of industry. The persons who need technical education are the masters much more than the men."

Throughout the whole article, of which we have here presented so extended an abstract, the evidence is strong that the dangers of that amateurism and of that officialism which are now beginning to awaken intelligent men, and especially men of science and men of applied science in the United States, to serious apprehension relative to all public services involving scientific work or development, have secured a firm and dangerous hold in Great Britain and constitute undoubtedly one of the elements of that apparent relative retrogression in the industries which has of late attracted so much attention and awakened such earnest discussion in the scientific and technical journals, and even to some degree in the columns of the 'Thunderer' itself. The republication, by the Harpers,* of letters to *The Times* from a British engineer visiting the United States, furnishes and preserves an interesting and instructive commentary upon these facts.

R. H. THURSTON.

MUSEUM METHODS ABROAD.

THE appearance of the eleventh annual report of the Museums Association, of Great Britain, reminds one that it is as nearly as possible eleven years ago that the Association of American Naturalists decided that so far as museums were concerned nothing remained for

* 'American Engineering Competition.' New York and London, Harper and Brothers. 1901. 8vo. Pp. 139.

it to do. The present report consists of xxiv + 157 pages, a trifle larger than the average of the reports, and besides the matter pertaining solely to the workings of the Association, comprises the address of the president, Dr. Henry Woodward, twelve papers, general notes, museum reports and a list of museum publications. Dr. Woodward's address is practically a brief review of the relations of the British Museum to the public and what it has done in the way of the arrangement and display of specimens to interest and instruct visitors, particular attention naturally being given to the display of paleontological material. Dr. Woodward has come to the same conclusion as that expressed by the writer some years ago in SCIENCE, that the complete mixture of recent and fossil animals in the exhibition series is inadvisable and the best results are to be obtained by introducing a few carefully selected and typical examples of living animals into the series of fossils, and rounding out the display of recent animals by the introduction into the exhibition series of a few fossils. "This limited introduction of existing forms, aided by diagrams, drawings and separate parts, does not break up the arrangement of the collection (of fossils) as a whole, but vastly enhances its usefulness to the student."

The aims and arrangement of various museums are described in more or less detail in several papers, including the Hastings Museum, Worcester, by W. Edwards; the Horniman Museum, London, by Richard Quick, and the Norwich Castle Museum, by Henry Woodward.

W. M. Flinders Petrie discusses the question of a 'National Repository for Science and Art,' advocating the acquisition of about a square mile of land within an hour of London (the scheme naturally applies to all large collections) on which should be built a series of one-storied galleries lighted from above; these galleries to be 54 feet wide and about 400 feet apart. The object to be attained by this method is to provide ample room, at a moderate cost, for the housing of material which would be at once preserved and available for study, museums in large cities whose cost of maintenance is high being largely devoted to exhibition.

F. A. Bather described a series of 'Exhibition Labels for Blastoidea,' specially intended for the student who goes to a museum with a definite purpose of acquiring information regarding fossil crinoids. Incidentally we are given a suggestion for a dichotomous arrangement of a museum. The text of the 44 labels is given and they practically amount to a condensed text-book with the specimens serving as illustrations. No one will deny the value of such a system to the student, but would an entire museum thus planned and labeled appeal to the general public, for which, after all, the exhibition portion of a museum is intended?

The 'Reproduction of Art Objects' is treated by Robert F. Martin, who notes that Venetian glass, old majolica, bookbindings, bronzes and even tapestries are now successfully duplicated, so that art museums may by the use of these reproductions fill gaps in historical series for a comparatively small price, where originals would either cost large sums, or be quite unobtainable.

J. W. Carr explained the use of 'Photography in Museum Work' for illustrating features which could not be adequately represented by specimens alone. Among such he instanced various geological phenomena; the habits and habitat of animals; forest trees and the general facies of the landscape caused by differences in the flora.

At the business meeting of the association the question of publishing a monthly journal devoted to museum matters was the subject of a 'Report from the Council,' and while the project was not then definitely settled, it has since been decided to publish such a periodical. The details have not as yet been made public.

F. A. L.

THE SCIENTIFIC ALLIANCE OF NEW YORK.

RENEWED efforts are being made to secure an adequate building for the societies composing the Scientific Alliance of New York. Mr. J. Pierpont Morgan has made a conditional subscription of $25,000, and several smaller amounts have been subscribed. A Committee of Cooperation with the Council of the Alliance has been formed consisting of Andrew H. Green, *Chairman*, 214 Broadway, Edward D. Adams, Abram S. Hewitt, W. E. Dodge, John S. Kennedy, Andrew Carnegie, F. W. Defoe, J. Hamp-

den Robb, D. Willis James, Sam'l Sloan and John J. McCook. This committee has issued the following appeal:

The Council of the Scientific Alliance of New York, composed of delegates from the New York Academy of Sciences, the Torrey Botanical Club, the New York Microscopical Society, the Linnæan Society of New York, the New York Mineralogical Club, the New York Section of the American Chemical Society and the New York Entomological Society, is endeavoring to obtain by subscription a fund for the erection of a building for the use of these societies and others joining the Alliance.

The building is needed as a common meeting-place for the societies, which now occupy rooms in various parts of the city, for the housing of their libraries, which are now widely scattered, for a large lecture hall, for laboratories and other rooms for scientific research, and as a central point of influence upon the community.

The scientific societies are about the only agencies of modern culture for which permanent homes have not been provided in the Metropolis. In this respect New York is strangely behind many smaller cities in the United States, and suffers still more in comparison with the great cities of Europe, most of which have creditable buildings devoted to the use of such organizations. As much original scientific research is carried on in the city of New York as in any other city of the United States, and only public encouragement and support of its already very efficient societies are needed to make New York the scientific center of the country.

The Council of the Scientific Alliance has been incorporated by a special act of Legislature, with power to acquire real estate and to receive bequests. It holds as a nucleus for the present undertaking the sum of $10,000, contributed by Mrs. Esther Herrman, and a number of smaller subscriptions. It is estimated that land can be purchased and a suitable building erected and equipped for the sum of $500,000, which it is the aim of the Alliance to raise.

The undersigned Committee of Cooperation with the Council commend the undertaking and urge all public-spirited citizens to unite with them in the endeavor to bring it to a speedy realization. Subscriptions will be received by the chairman of the Committee or by any member of the Council.

MEMBERSHIP IN THE NATIONAL ACADEMY OF SCIENCES.

IN view of the fact that the National Academy of Sciences is about to hold its annual meeting at which new members are elected, it may be of interest to give the members of the Academy who have died and who have been elected during the past ten years.

Deaths.		*Elections.*

SCIENTIFIC NOTES AND NEWS.

THE National Academy of Sciences will hold its stated annual meeting at Washington on April 16th, 17th and 18th.

THE spring meeting of the Council of the American Association for the Advancement of Science will be held in the Assembly Hall of the Cosmos Club, Washington, on Wednesday, April 17th, at 4.30 p. m.

DR. GEORGE DAVIDSON, professor of geography in the University of California, has been elected a correspondent of the Paris Academy of Sciences.

PROFESSOR F. G. HESSE, who holds the chair of mechanical engineering in the University of California, was offered a banquet at San Francisco on March 29th to celebrate his twenty-five years of service in the University of California. About 150 of his friends and former students were present and speeches were made by Professor Joseph Le Conte and others.

A PORTRAIT of Dr. W. W. Keen, professor of surgery in the Jefferson Medical College, Philadelphia, has been presented to the institution by his colleagues and students. Dr. Keen, as we have already noticed, has been granted a long leave of absence for travel abroad.

THE fiftieth anniversary of Dr. Abraham Jacobi's doctorate was celebrated at the New York Academy of Medicine on April 3d. Dr. Jacobi was introduced by Dr. R. F. Weir, the president of the Academy, and read a paper on 'German Medical Text-books of Half a Century Ago.'

PROFESSOR J. MARK BALDWIN, of Princeton University, has sailed for Europe to supervise the publication of the second volume of the 'Dictionary of Philosophy and Psychology,' which is printed by the Oxford press, and to arrange for the translation of the work into foreign languages. It is expected that the first volume will be published in a week or two.

DR. J. A. BERGSTRÖM, associate professor of psychology and pedagogy in the University of Indiana, has been given leave of absence in order that he may study the school systems in Germany and Sweden.

PROFESSOR GEORGE FREDERICK WRIGHT was given a reception on April 4th, by the students of Oberlin College, on the occasion of his return from his geological trip round the world.

E. R. CUMINGS, of the department of geology of the University of Indiana, has been given leave of absence in order to carry on his studies at the Johns Hopkins University.

MR. CHARLES P. STEINMETZ has been nominated by the Council of the American Institute of Electrical Engineers for president. In the ballot of members Mr. Steinmetz received seventy-six votes, Mr. L. B. Stillwell sixty five and Professor M. I. Pupin forty-four. The Institute will hold a conversazione at Columbia University on April 12th.

M. FAYE has been appointed president of the Council of the Paris Observatory for the present year.

M. SABATIER, of Toulouse, has been elected a correspondent in the section of chemistry at the Paris Academy of Sciences.

THE Midland Railway Company, of Great Britain, is sending two engineers, Messrs. Seeley and Woollinscroft, to the United States to study American railway methods, including the use of electricity.

MR. VAUGHAN CORNISH has returned, as we learn from the London *Times*, from an expedition in search of snow waves in Quebec, Manitoba, the Northwest Territories and British Columbia. These waves were found to be well developed on frozen rivers and lakes and on the open prairie, where photographs and measurements were taken. They are produced without the intervention of any obstruction, and sometimes occur in groups or trains of waves comprising 100 succeeding ridges. Their movement is sufficiently rapid to be readily visible. In certain conditions of the snow true ripples are also formed, which are similar to the ripples produced by wind in loose, dry sand. In both ripples and waves the steeper face is on the lee side. In moist or coherent snow, such as usually falls in England, the wind carves the surface into ridges, which have their steep face on the windward side.

MR. WILLIAM KENT, of New York City, author of 'Kent's Mechanical Engineers' Note

Book' and of 'Steam Boiler Practice,' also associate editor of the *Engineering News*, is to deliver a series of six lectures before the senior students in engineering of Purdue University, Lafayette, Ind. The lectures of Mr. Kent will extend through the week beginning April 15th and will close a long series of lectures delivered at Purdue by outside engineers.

THE death is announced of Audubon Whelock Ridgway, assistant in the Department of Ornithology of the Field Columbian Museum, Chicago. He was born in Washington in 1877, and was the only son of the eminent ornithologist, Dr. Robert Ridgway.

THE death is also announced, at Berlin, of Dr. Schlichter, the African traveler and geographer.

DR. C. R. ALLEN, vice-president of the Torrey Botanical Club, has presented the New York Botanical Gardens with his valuable collection of stoneworts.

THE *Astronomical Journal* states that the following grants from the Gould Fund have recently been made: to Mr. John A. Parkhurst, $30; to Dr. Herman S. Davis, $500; to Mr. Paul S. Yendell, $225; to Professor Simon Newcomb, $25. A considerable additional amount of income has accrued, for the distribution of which applications are awaited. These applications may be made by letter to any of the directors, stating the amount desired, the nature of the proposed investigation, and the manner in which the money is to be expended. The directors, desiring to stimulate the participation of American astronomers in the attempt to bring up the arrears of cometary research, offer to them the sum of $500 for computation of the 'definitive' orbits of comets; this sum to be distributed at the average rate of $100 for each computation—the amount to vary according to the relative difficulty of the computation, and to be determined by the directors of the Gould Fund. Computers should promptly notify the directors of their participation or desire to participate, and manuscripts should be submitted not later than July 1, 1902.

IT is stated in *Popular Astronomy* that Dr. Lewis Swift has disposed of his astronomical equipment to the Pasadena and Mount Lowe Railway. The instruments are to remain on Echo Mountain, and Professor E. L. Larkin is now director of the observatory.

DR. PATRICK GEDDES, who was responsible for the formation of the International Association for the Advancement of Science, Arts and Education, and the holding of an International Assembly at the Paris Exposition last year, proposes a similar assembly, in connection with the exposition and congresses to be held at Glasgow this year.

THE Zoological Society of London has arranged the following lectures to be held after the general meetings on Thursdays, April 18th, May 16th, June 20th and July 18th:

'On the Protection and Nourishment of young Fishes': Professor C. STEWART, LL.D., F.R.S.

'Biological Stations at Home and Abroad.' With lantern illustrations: Professor W. A. HERDMAN, F.R.S.

'Mimicry.' With lantern illustrations: Professor E. B. POULTON, F.R.S., F.Z.S.

'Rhinoceroses, Recent and Extinct.' Mr. F. E. BEDDARD, F.R.S., F.Z.S.

THE laboratory of the U. S. Fish Commission for the study of marine biology, at Beaufort, N. C., will re-open for work on the first of May, and will remain open through September. The laboratory is open to those wishing to carry on botanical or physiological work, as well as to those engaged in zoological investigations. The usual histological apparatus and reagents are provided, and the collecting outfit includes a steam launch with dredge and trawl. The more commonly used journals will be kept on file. There is no charge for tables. Applicants for tables should address Hon. Geo. M. Bowers, U. S. Commissioner of Fish and Fisheries, Washington, or Professor H. V. Wilson, University of North Carolina, Chapel Hill, N. C. Inquiries as to climate, accommodations, etc., should be addressed to the latter.

THE ship built for the use of the German Antarctic Expedition was launched at Kiel on April 1st, in the presence of a distinguished company. The vessel has been named *Gauss* in honor of the great mathematician.

THE census of France was taken on March 24th. The results are looked forward to with

special interest, owing to the small increase in the population in recent years. In the census taken five years ago the population of France was 38,517,975.

THE Navy Department for some time has been giving attention to the subject of wireless telegraphy, with a view of ascertaining how far it can be practically applied to the naval service, and Secretary Long has appointed a special board of officers to make a thorough inquiry on the subject. The board consists of Captain Chadwick, Lieutenant Powellson and Lieutenant Commander Hodgson. The meeting of these officers will take place at Newport, and it is expected that their conclusions will determine to what extent the wireless system can be utilized for the Navy.

IN order to make the free distribution of seeds by the U. S. Department of Agriculture as useful as possible, Secretary Wilson has secured authority to send out young trees as well as seeds.

THE Senate of Minnesota has passed Senator Chilton's bill prohibiting the marriage of insane, epileptic and idiotic persons, and requiring a medical certificate of all applicants for marriage licenses.

THE American Social Science Association will hold its general annual meeting at Washington, beginning on Monday evening, April 15th, and continuing four days.

UNIVERSITY AND EDUCATIONAL NEWS.

IT is said that the litigation over the Lamson estate, bequeathed several years ago to Yale University, has ceased and the University will at once receive about $450,000. Of this sum $150,000 is to be used for an auditorium and the balance for the endowment of professorships in Greek, Latin and English.

IT has been announced that the donor of the $200,000 to the University of Pennsylvania for a new physical laboratory is Mr. Randolph Morgan, of Philadelphia, one of the trustees. The laboratory will be known as the Morgan Laboratory of Physics.

THE senate of Cambridge University has accepted a tender for the erection of the new botany schools at a cost of over $100,000.

THE trustees of Harvard University have purchased about 400 acres of land near Centre Harbor, on Squam Lake, in New Hampshire, to be used as a camp where surveying will be taught during the summer months.

A ROYAL commission is to be appointed to enquire into the question of university education in Ireland.

THE Committee of Fifteen, appointed by the National Council of Education in 1898, to consider and report upon the question of a national university at Washington, will hold a meeting to formulate its final report, at Columbian University, Washington, on Thursday, May 23d, and following days. It will be remembered that the preliminary report of the Committee was adverse to the establishment of a national university, in the usual use in which the word 'university' is used ; but it has in contemplation the development of a plan to make systematic use of the resources of the Government at Washington for research and investigation by university students.

THE courses in medicine for women, in connection with the University of St. Petersburg, have been closed indefinitely, owing to the recent riots in that city.

DR. G. A. MILLER, instructor in mathematics in Cornell University during the past four years, has just accepted an assistant professorship in the Leland Stanford, Jr., University, and will leave for his new field of work soon after the close of the Cornell Summer School in which he takes part. Readers of SCIENCE will recall that only a few months ago, Dr. Miller was awarded the prize offered by the Royal Academy of Sciences of Cracow for the solution of a question in groups, this competition being open to the world.

DR. C. N. MCALLISTER, assistant in the Yale psychological laboratory, has been appointed lecturer in experimental pedagogy at Yale University.

THE Trustees of Ohio State University have elected John A. Bownocker professor of inorganic geology and Charles S. Prosser professor of geology and head of the department.

*THE MORPHOLOGICAL MUSEUM AS AN EDUCATIONAL FACTOR IN THE UNIVERSITY SYSTEM.**

THE educational value of the modern morphological museum has of late years received such general recognition that we may well regard its position as established in the university system. Not only do the departments of undergraduate instruction draw more and more extensively upon this portion of the university equipment for the illustration of courses and demonstrations, but the museum itself has assumed its proper relation to independent scientific research and to the investigation of biological problems. It has seemed to me desirable to present to this association—whose members are so largely both teachers of anatomy and investigators of the science—some account of the progress made during the last decade in museum work in the department of vertebrate morphology. More especially does it appear proper at this time to note the present stage of development of the modern anatomical museum, because we have, I think, reached a period at which we can look back over a series of busy years and gauge correctly the value of the results obtained, as well as forecast the probable future development of this work. Ten or fifteen years ago the morphological

* Address of the President before the Association of American Anatomists at the Fourteenth Session, held at Baltimore, Md., Dec. 27–28, 1900.

museum—established on lines of modern thought and research—existed in an embryonic form in only a few of our institutions of learning. From this period date a number of excellent monographs—in which the authors outline the plans of a proposed anatomical museum designed to meet the requirements demanded by the advance of the biological sciences—from the standpoint both of the teacher and the investigator. Prominent among these interesting publications are the following:

'Outlines for a Museum of Anatomy. Prepared for the Bureau of Education,' by R. W. Shufeldt. 1885.

'Die Aufgaben der anatomischen Institute,' by Professor A. Koellicker, 1884. An address delivered at the opening of the new anatomical institute in Würzburg on November 3, 1883.

'The Educational Museums of Vertebrates,' an address before the Section of Biology of the American Association for the Advancement of Science, at Ann Arbor, August, 1885, by Professor B. G. Wilder.

'The Synthetic Museum of Comparative Anatomy as the Basis for a Comprehensive System of Research,' by John A. Ryder, Professor of Comparative Embryology at the University of Pennsylvania, Philadelphia. 1893.

As I look over the list of these and other contributions to the literature of the anatomical museum I am tempted to characterize the period between 1885 and 1895 as the prophetic era, foreshadowing the establishment and recognition of the most essential and valuable aid to scientific anatomical instruction and research which our universities to-day possess. When we analyze the great and radical changes which our methods of morphological teaching have experienced since that time, we shall, I believe, agree that the demonstrative and objective instruction which has replaced so largely the old didactic lecture is intimately and organically connected with the evolution of the modern anatomical museum. It will perhaps best serve the purpose of my communication if in the following I confine myself to the facts as they are most familiar to me in the case of my own university, which, I believe, may fairly be taken as a concrete example of the general progress which has marked the period in question in the scientific institutes throughout our country.

The establishment of a museum of vertebrate comparative anatomy, on lines designed to illustrate and demonstrate to the fullest extent possible the morphological truths embodied in the doctrines of evolution, heredity and descent is an undertaking requiring years of careful and successful work before even a satisfactory beginning is made. The foundation of the museum at Columbia University was laid in 1889, and, while in many directions our progress has been rapid and the results gratifying, yet we feel that to-day but the outlines exist along which future growth is to take place.

I. PLAN AND SCOPE OF THE MUSEUM AND ITS RELATION TO ANATOMICAL INSTRUCTION.

I may in the first place call your attention to the general plan and purpose of the museum, in accordance with which the objects have been collected and prepared, and to the relation existing between the museum and the undergraduate instruction in anatomy.

The following considerations present themselves:

1. The fundamental plan of the museum includes in the first place a general exposition of the vertebrate classes, whose purpose is to present the cardinal points in the anatomical structure of the great vertebrate classes and subclasses.

Each vertebrate class, subclass and order

is represented by one or more typical forms in preparations illustrating as fully as possible the skeletal and locomotory apparatus, the circulatory and nervous systems, and the alimentary, respiratory and uro-genital tracts.

This display forms the guiding thread to the study of the individual forms—in respect to typical structures, *i. e.*, the fundamental anatomical characters of the mammal, bird, reptile, amphibian and fish are grouped together to afford a comprehensive view of the entire organism, from which starting point the detailed investigation of characteristic structures in their various modifications is to be followed through the series of species belonging to the *same class*.

To illustrate: the typical structure of the avian pectoral girdle is represented in the collection by the girdle of *Palamedea cornuta*, the horned screamer. It is here shown to contain three elements, the scapula, coracoid and furcula.

Turning to the corresponding series demonstrating the successive modifications of this structure, we find it as a link in the group devoted to the development of the vertebrate shoulder girdle. The various modifications in shape, extent and sternal attachment of the complete furcula are first illustrated, together with preparations of the membranous and ligamentous structures, which have a bearing on the general morphology of the episternal apparatus.

In the next place the avian girdle is found to pass from the type represented by *Palamedea*, in which all three skeletal elements are fully developed, to the intermediate condition seen in the toucan, where the furcula is developed as a bilateral structure, the two segments not fusing over the sternum, until we come to the brevipennate group of birds, of which *Dromæus* still has rudimentary anterior collar bones, whereas in *Struthio*, *Rhea* and *Casuarius* these have lost their identity by becoming fused with the scapula.

In the second place this division of the museum affords the basis for broad comparison between the organizations of the different vertebrate classes. For example, the comparison of the entire anatomical system of a typical reptile, bird and mammal will show why reptiles and birds, although differing widely in structural detail, yet have sufficient general morphological characters in common, as against the mammal, to entitle them to be grouped under the single broad head of the Sauropsida.

Then again, this portion of the museum is designed to elucidate the important problems of derivation of vertebrate sub-classes.

2. The second main division of the museum deals with the development, evolution and comparative structure of single organs and systems. The homologies in the different classes, and the modifications of the typical structures in each class, are here demonstrated as completely as possible. In many respects this portion of the work is educationally the most important. We draw most extensively upon it for our anatomical undergraduate instruction in the elucidation of problems in human morphology. I cannot take time in even superficially outlining the detailed development of this division of the anatomical museum. The enumeration of a few of the principal series must suffice.

I may instance the series dealing with the morphology of the alimentary tract, and especially the group devoted to the structure of the ileo-colic junction, cæcum, vermiform appendix and the allied segments of the large intestine. This series, including at present over 600 preparations, and beginning with type forms illustrating this portion of the alimentary canal in fishes, amphibia, reptiles and birds, passes to a complete demonstration of the structures in mammals, terminating with several speci-

mens of the four anthropoid apes and leading up to the detailed study of the human cæcum and appendix, the numerous variations of which are all represented by one or more type specimens. In the same way the various forms of the stomach and the modifications of small and large intestine constitute a series of great morphological interest.

Other series deal with the vertebrate respiratory apparatus, especial stress being laid on the clear demonstration of the development, evolution and structure of the mammalian lung. Closely connected with this group is the serial exhibit dealing with the heart and circulatory system. Other series include the nervous system, the genito-urinary tract, the pelvic and pectoral girdles, the mammalian temporal, periotic and tympanic bone, etc.

Special attention is given in this department of the museum to the demonstration of human anatomy. Eventually it is hoped that every portion of man's structure will be fully and exhaustively illustrated by perfect preparations. The museum should afford the medical student the opportunity of directly verifying his text-book information and should be a most valuable guide and aid to the practical anatomical study of the individual in the dissecting room. Moreover, many structures, as we all realize, are never fully examined or completely demonstrable to the student in the dissecting room. Aside from the individual differences in the cadaver in respect to development and state of preservation, and in the element of alteration of structure by diseased conditions, certain parts require special methods of preparation, such as the auditory apparatus; others necessitate for their exposition the sacrifice of surrounding structures to a degree not warranted by the practical requirement of getting the greatest amount of detail from the dissection of a single cadaver. Moreover, even the structures, which are ordinarily fully examined and demonstrated in the dissecting room on the fresh subject, can be shown with great profit in the museum in various preparations by different methods. For example, the museum contains hardened situs preparations, organs hardened, distended and fenestrated, injection and corrosion preparations, etc., to illustrate fully the anatomical structure of each part and to enable the student to extend and amplify his observations on the cadaver.

Again, in connection with this department of the museum, I find it of distinct advantage to establish small comparative series designed to illustrate the development and normal anatomy, as well as the more important variations, of certain adult human conditions. These groups are accompanied by tablets, describing as fully as necessary the purpose of the exhibit, and drawings which emphasize the points at issue.

Thus, for example, under the heading of the cardinal sinus of the adult human heart —as part of the series exhibiting cardiac anatomy—the following group is placed with full explanatory text:

1. Heart and vascular system of *Raja ocellata*—various preparations to show embryonic type of mammalian heart before septal division, ducts of Cuvier and symmetrical cardinal veins.

2. Heart of *Python molurus*—hardened and distended, with sections showing: (*a*) sinus venosus of right auricle; (*b*) valves of sinus venosus and their relation to the Eustachian and Thebesian valves of the mammalian heart; (*c*) pulmonary veins; (*d*) persistent left precava.

3. Heart of *Struthio africanus*—injected, showing persistent avian left precava—with its relations to pericardium and coronary vein.

4. Ruminant heart (*Antelope cervicapra*) —mammalian type of normal persistence of left precava.

5. Series of normal human hearts—showing, in various preparations, coronary sinus, Thebesian and Eustachian valves—both fœtal and adult.

6. Series of well-developed folds of Marshal in fœtal and adult hearts.

7. As soon as obtained the final member of this group will be added as a preparation showing the normal persistence of the left precava in the adult human subject.

Instances in which a similar limited and selected group of preparations may be with advantage established for the elucidation of special details in human anatomy could be almost indefinitely multiplied.

I have noted at random:

1. Development of axis and atlas.

2. Ligaments and tendons of shoulder joint.

3. Greater and lesser sciatic ligaments and relation to hamstring muscles and coccygeus.

4. Postcava and variations.

5. Carpus and tarsus.

6. Sacrum and vertebral variations.

7. Aortic arch and variations of primary branches.

8. Various myological problems.

9. The peritoneum.

The question as to the practical application of this educational material to the requirements of undergraduate instruction in anatomy deserves careful consideration from several points of view:

1. Primarily the museum should afford a consecutive and logical serial exhibition, arranged and administered in such a manner that for both undergraduates and advanced students the preparations should be readily accessible and capable of being examined with only such restrictions as the safety of the object demands. The museum should be the reference library of the student in the widest sense, where the undergraduate can review and extend his anatomical knowledge on the hand of the actual object of his study, and where the advanced worker will find the necessary material in directing and supplementing his research in any given problem under investigation.

2. In the demonstrative teaching of the anatomical course the material of the museum in our experience can best be utilized in two ways:

a. It is our custom, in approaching any one of the large subdivisions of the course—such as the respiratory and circulatory system, the alimentary canal or genito-urinary tract—to devote a portion of the available time to a preliminary general consideration of the development, peculiarities of morphological structure and the physiological significance of the parts involved. For this purpose a judicious selection of a limited number of the museum preparations is made, and the objects are arranged in the form of a series, each number of which distinctly and forcibly illustrates a developmental stage or a significant and important structure or functional fact. It is necessary to limit the preparations thus selected in number to avoid confusion and superfluous expenditure of time, but it is surprising how clearly and convincingly the main broad lines of vertebrate development and evolution and the relation between structure and function can be brought out in a comparatively short series of selected preparations. Every teacher knows and appreciates the difference in the quality of instruction and its results between a demonstration of models and drawings, schematic or otherwise, and one referring directly to the natural object. The most important function of the museum, as an integral part of the educational system of the university, is exerted in supplying the material necessary for this kind of demonstrative teaching. Practically I find in the schematic blackboard sketch or the more carefully

prepared colored chart a most valuable adjunct. The drawing should, however, be made directly from the actual preparation demonstrated and the student should have the opportunity of directly comparing both. In this way salient points can be accentuated and the attention properly and immediately directed to the important facts which the preparation is designed to illustrate.

b. In connection with the class-room demonstration it is at times desirable to deal with general problems of vertebrate morphology from the higher standpoint which, on the hand of a more extensive series, affords a wider view of the structures concerned. I find that this can best be accomplished by a photographic lantern slide demonstration, in which a very considerable number of forms can be exhibited to the class in a comparatively short time. It has been our practice to photograph the preparations when finished, but before they are permanently mounted or included in the museum series. As a practical matter the best results are obtained by vertical exposure, the object being placed in suitable trays and covered by clear fluid—water or alcohol. In this way the disadvantage, resulting from the distorsion and reflection of the jar containing the specimen when finally mounted, is obviated.

The resulting photograph forms part of the museum record and is useful in many ways. Properly labeled, it forms an excellent guide to the study of the preparation and it can be used directly for reproduction in publications or be made the basis of the drawing. Finally, as the completion of the series warrants it, the negatives yield a set of lantern slides which can be used in the teaching of the department as well as in extending the use of the museum material in other institutions.

3. The special courses in comparative anatomy and embryology, which are offered as optionals, electives, or for the higher university degrees, make demands which the museum should meet as fully as possible. In the first place, I find that the forms which can readily be obtained in numbers, and supplied to the students for their actual personal use in the laboratory courses, require in many cases comparison with allied types which, by reason of their rarity and value, can only be represented in the permanent collection of the museum. The courses can thus be extended and made infinitely more valuable and instructive. Again, every practical laboratory teacher will know the value of placing before the student a carefully and clearly executed preparation and reviewing the structures which he is to expose and determine for himself by the dissection of the fresh material on hand. This use of the museum is entirely apart from the valuable and instructive deductions which a series of significant variations of normal structures will enable the student to make.

Moreover, in many respects the museum fulfills one of its most important practical functions in enabling the teacher to direct the student's attention, at the proper points in any laboratory course, to the corresponding structures and their modifications in selected preparations ranging throughout the entire vertebrate series. The broad and general application of the knowledge gained by the detailed study of any individual form can only by these means be impressed on the student, and it is thus that the anatomical museum accomplishes one of the main purposes of morphological study.

II. RELATION OF THE MUSEUM TO ORIGINAL RESEARCH AND ADVANCED STUDY.

Of equal importance with the value of the museum for undergraduate instruction is its influence in promoting original investigation and advanced morphological study. Its very existence carries this with it. It constantly opens up, in creating the

nucleus around which the institution is to grow, lines of investigation and research which ultimately return their products to the museum as permanent records of the work accomplished, and thus prove sources of continual and valuable additions.

The museum in itself forms the basis for a progressive extension of morphological investigation. It accomplishes this in several directions. In the first place, the generalization of the structures presented by different types, which marks the central purpose of the institution, forms a circle from whose circumference at any point the line of a new and more extended investigation can be drawn. In fact, if the museum is to grow and develop according to its original intent, it is requisite that such enlargement should take place.

As the museum grows the vital questions of derivation and ancestry of forms must be investigated on the hand of constantly increasing material, which will open up points of view heretofore unattained. With each new accession to any group the capacity of the museum for extension of original thought and investigation increases. Any research opens at some point in its course side lines which may be of the utmost value. It is here that the immediate possibility of serial comparisons on a large scale afforded by the museum becomes of the greatest importance. The museum represents in its complete condition a morphological reference depository. It functions in connection with the morphological library, but it possesses the inestimable advantage of presenting the actual objects instead of plates and descriptions, often at variance with each other, incorrect and incomplete in detail and failing to elucidate just the question which it is desired to solve.

In this sense the museum fulfills its highest functions, stimulating and directly promoting investigation and rendering such investigation fruitful and effective by contributing the series necessary for comparison and reference.

It may hardly be necessary to touch on the effect of this work on those who are engaged in it. It attracts men whom the university is glad to number among its students and graduates, and who in other institutions—as teachers and investigators—will reflect credit on their training. If from among the growing numbers of our medical students even a few are made to develop into scientific workers, I should yet hold those few—in their prospective value to the university and to science—as balancing the long list of medical graduates whom we annually send out at our commencement.

III. RELATION OF THE MUSEUM TO OTHER DEPARTMENTS OF THE UNIVERSITY.

There is scarcely a department of biological or medical instruction and investigation which is not in intimate relation with some portion of morphology, and which will not benefit by a connection with the museum and by access to its collections.

In physiology, the science dealing with the function of the machine which itself is the object of the study in morphology, the connection is obvious. But the tremendous advantage which will accrue to each of these sciences by closer mutual association, through the link of the comparative anatomical museum, can scarcely be estimated. Morphology offers in the series of modifications which different forms present in their structure, a field of nearly unlimited choice for the interpretation of the physiologist. The physiological study of an organ in a certain form—as the dog—may lead the investigator to certain results which apply in the first plan to the species examined. If now the morphology of the organ is accessible to the physiological investigator not only in a complete series of

the dog's own order, the Carnivora, but through the entire mammalian class, and beyond this limit, so as to include the homologous structures, in other vertebrate classes, the result of the investigation becomes potentially amplified to a corresponding degree. The investigator can not only reason from analogy as to the results of similar experiments extended as far as deemed advisable through the vertebrate classes and orders, but he can also, guided by the morphology of the structure under consideration, select types which, from their anatomical configuration, promise unequivocal confirmation and extension of the results yielded by the first experiment. How frequently the success of an investigation depends on details of anatomical structure every physiologist will attest. It is often the question of the length of an arterial vessel without branches, or the arrangement of a duct, or the combination of several peripheral nerves. The museum of comparative morphology converts a haphazard search for a suitable form into one which will select the most desirable type with certainty.

In turn the generalized view of organized structure obtained in the comprehensive system of the museum will afford to the morphologist the aid which is to be found in the broad physiological interpretation of the modifications exhibited. Thus these two fundamental departments will be brought into closer contact with each other, a contact which cannot fail to redound equally to the benefit of both. I believe that a closer association of anatomy and physiology, such as is afforded by the link of the museum, is of very distinct advantage in undergraduate instruction. The modern development of science inevitably leads to a high degree of specialization, which naturally becomes apparent in the teaching of any department. The general advantage of this is obvious, provided touch is not lost with cognate branches. The morphological museum preserves this vital connection between anatomy and physiology more than any other single factor in the university equipment. Moreover, the museum has important relations to the practical departments of medical teaching and to pathology. Nearly all important advances, especially in departments such as diseases of the eye and ear, the diseases of women, surgery in general and in its specialized branches, depend primarily on some morphological question for their inception, rendering this or that proposed operative interference proper and advantageous, or interdicting it.

A museum which offers to the medical specialist not only the normal and variant human structures which constitute his field of work, but which enables him at the same time to examine the homologous parts of other vertebrates for the purpose of gaining clearer insight into obscure morphological conditions and the origin of aberrant formations, will certainly be an aid to practical advance which can be obtained by no other means. It is needless to point out further connections of a similar character, or to more than touch upon the line along which pathology and embryology meet, a line which is sufficiently extensive, but obscure because the assistance which vertebrate embryology can afford to the pathologist is only rarely attainable in the form which the museum proposes to offer, viz., complete sets of serial preparations. As the museum develops it is proposed to take successively certain portions of the subject, such as eye, ear, larynx, brain, genito-urinary tract, etc., and to develop these as fully as possible, demonstrating the results in the form of an exhibition to a selected number of scientific men who are directly interested in the matter as expert specialists. The importance of this feature of the museum work will thus be brought more

particularly to the attention of those best able to judge of its value and to profit by the same. I have no doubt that from this class of men valuable work in investigation will be secured.

IV. UTILIZATION FOR THE PURPOSES OF THE MUSEUM OF THE MATERIAL OBTAINED FROM THE DISSECTING ROOM, AND REFERENCE COLLECTION IN OSTEOLOGY.

The question has at times been discussed whether the morphological museum should take its place in the university system as part of the departments of general biology and zoology, or as an integral division of the department of anatomy in the medical school. I am unhesitatingly of the latter opinion. Aside from the obvious relation to undergraduate medical instruction which I have attempted to outline above, the mere fact that man, the highest vertebrate of the series, forms the object of study in the medical curriculum, assigns to the morphological museum its logical place in the university system. The human material necessary for the completion of the museum series is to be obtained from the supply of the medical school. The typical preparations are, of course, from specially selected subjects set apart for the purpose. Besides this, however, one of the important functions of the museum is to supervise the records of the dissecting room, to collect and arrange the statistical information afforded by the constantly repeated examination of the human body, to acquire for its own purposes the preparations which either illustrate normal structures unusually well or demonstrate important and significant variations. Part of this material is capable of direct incorporation in the museum series after removal from the cadaver and proper preparation. For other objects the method of plastic reproduction by means of casts is invaluable. This applies especially to the great group of myological variations. Not only are the objects bulky and not well adapted for preservation as moist specimens, but casts actually better serve the purposes of the museum in exhibition and instruction. In the comparative myological series, with which human muscular variations are necessarily brought into intimate relation, the method of plastic reproduction is an essential. The full utilization of rare and valuable animals requires this method because superficial structures must be removed before the deeper parts can be reached. As the superficial muscles are exposed casts of the different regions are taken in various positions. In the same way, by casting the deeper layers as they are successively reached, permanent records of the greatest value for myological study and reference are attained. The casts, together with the notes and drawings of the dissection, form a complete and readily accessible record far exceeding in value and accuracy any other method of illustration. Again, for example, in dealing with the development and modifications of the extremities in the vertebrate classes, each group is accompanied by casts of the entire hand and foot, forming, together with the preparations of the soft parts, muscles and ligaments and the skeleton of the extremities, a complete series. For purposes of instruction this method has proved itself very valuable. Thus a carefully prepared and hardened liver showing the natural surfaces and impressions, which are ordinarily lost in the organ removed from the body before hardening, and which are hence not ordinarily recognized, has been cast and reproductions prepared in sufficient numbers to allow one to each student for personal examination during the demonstration of the organ to the class. This plan, when extended as purposed by the museum, will vastly add to the effect and value of our demonstrative teaching.

The development of the facilities for plastic reproduction of morphological objects enables the museum to enter into connection with other institutions for purposes of exchange and scientific intercourse.

In connection with the utilization of the human material for the museum I desire to mention briefly the Reference Collection in Osteology, as part of the plan of offering opportunities for extensive morphological and anthropological research. This collection includes:

1. The disarticulated skeletons of vertebrate animals.

These are kept in boxes, arranged like the books of a library, accurately catalogued and indexed, so that any desired skeleton can be immediately found and used. The collection is placed in the osteological laboratory. It is proposed to make the collection thoroughly representative, and to include sufficient individual specimens of each form to avoid erroneous deductions possibly based on unusual variations.

2. The department includes, in the second place, a reference collection of human bones, on a scale which renders possible a thorough comparative study in reference to racial character, variations, reversions, age and sex differentiations, etc. The collection is now approaching the limit which we originally designed for it, viz., 5,000 specimens of each of the bones of the human body, but will be extended beyond this point. I am gratified that this material has afforded one of our members, Dr. A. Hrdlicka, opportunity for some very interesting researches, some of which have already been presented to this association, while his more recent results are to come before us at this meeting. The value of the collection is greatly increased by our system of record-keeping, which makes the material available for anthropological study in the widest sense. We obtain now, from the hospital records, the necessary data as to parentage, age, birthplace, etc., of each subject delivered at the college. These data are entered upon the record under a running number, which follows each bone on a lead tag through all stages of maceration and preparation until it is turned into the reference collection as finished. Consequently this collection does not represent merely a catacomb of human bones indiscriminately packed together, but each bone, with its origin and history clearly indicated, becomes a member of a series available for scientific comparative work.

The same system is applied to all variations of the soft parts obtained from the dissecting room, and the variation collection of the general museum becomes in a like manner the means of promoting scientific inquiry into the causes and conditions at present operative in human evolution.

V. DEPARTMENTAL LIBRARY.

I may merely mention that a good working morphological library, containing the standard works and the more important current periodicals, forms part of the accessory equipment of the museum.

VI. LABELING AND CATALOGUE.

In conclusion I may briefly refer to the method of labeling and cataloguing the collection which we have found most useful.

The catalogue is divided into the *general* and *accession catalogue*. Each specimen as received is given an *accession number*. On the card slip, corresponding to the number in the accession catalogue, are entered all the data concerning the animal, as source of supply, date of receipt, weight of body and of individual parts, presumable age, sex, method of preparation, individual peculiarities, etc., and finally a complete list of the finished preparations derived from the

animal as they are incorporated in the museum.

The general catalogue carries on each card the running number of the preparation and beneath the same the accession number of the animal from which the specimen is taken. It is thus possible, while avoiding needless repetition, to ascertain at once the details concerning any preparation by reference to the accession catalogue. The cards of the general catalogue are arranged in accordance with the serial exhibition of the museum. The running number of the general museum and the accession number appear on the label of each preparation. In addition the individual preparations carry two small disks of a bright color with a number. These are the complementary numbers of the preparation, referring it to some other group with which it is related, as well as indicating its position in its proper series. For example, the shoulder-girdle of the armadillo assumes its proper place in the series demonstrating the structure of this portion of the vertebrate skeleton, and is numbered accordingly on a green disk, so that its own place in the series is preserved, green being the color of that division of the museum which deals with the development of the pectoral and pelvic arches. If the armadillo's number in the series is 17, and an additional preparation enters the series next to it, it receives green number 17a, etc.

In addition to the green number a small red disk on the armadillo preparation carries a number which refers the preparation to its proper place in the series illustrating the general anatomy of the Edentates, red being the serial color of that division. So if it is desired to put together at once for comparison all the material contained in the museum for illustration of the Edentate type, every preparation carrying a red disk is taken out of its own series and the resulting group, when arranged in the sequence of the red numbers, forms the logical series treating of Edentate anatomy.

This plan makes every portion of the museum easily and at once accessible, and arranges the series in such a manner that each shall prove complementary to all the others.

By varying the shape of the colored labels and the character of the numerals sufficient range is obtained to meet all requirements.

In addition—as the series develop—more extensive typewritten tablets are introduced, giving the general features of the group and indicating the purpose for which it was assembled.

Photographs and drawings of the preparations, carefully labeled, are used for indicating points of special importance, in such a manner that they can be readily identified in the actual preparation. These accessories prove of aid in the use of the museum for individual study and during informal demonstrations and conferences.

I have attempted to outline for your consideration the present status of the morphological museum and its relation to the system of the university. I am convinced that the practical value of the institution will continue to make itself more and more felt, and its general adoption and development will be one of the prominent features marking our educational and scientific progress during the next decade.

GEO. S. HUNTINGTON.
COLUMBIA UNIVERSITY.

*SUGGESTIONS FOR AN ATTEMPT TO SECURE A STANDARD COLLEGE ENTRANCE OPTION IN BOTANY.**

THE rapid advancement of any science depends not only directly upon the re-

* Read before the Society for Plant Morphology and Physiology at the Baltimore Meeting, December 28, 1900.

searches of specialists, but also indirectly upon a favorable public opinion. Something may be done towards forming this opinion through a wide dissemination of information as to the true aims of science, but a more efficient method consists in the proper education of the coming public while it is still in school and college. From the single point of view of the advancement of his science, therefore, and apart altogether from the question of his responsibilities towards general education, it is the duty of every scientific man to contribute according to his ability towards elementary scientific education. Particularly is it the duty of every one of us connected with educational institutions to inform ourselves upon the present status and problems of this subject, and vigorously to set forth our resultant opinions upon all fitting occasions. It follows, further, that the problems of elementary scientific education are a proper subject for the consideration of any scientific society.

In these days the sciences are making great advances in education, and they are approaching, though for the most part they are still far below, the educational level of the older subjects. Amongst the sciences botany holds at present a less prominent place than it deserves; but, under the vitalizing influence of the dynamical and realistic spirit so recently infused into the subject among us, it is advancing to a greater prominence for the near future. Just at present, in botany as in many other subjects, educational discussion hinges chiefly about the contact of school and college, that is, about college entrance requirements. From this discussion three distinct educational advances are resulting: First, wider options in entrance subjects generally; second, a greater emphasis upon the sciences; and third, a determined movement to secure greater uniformity in the requirements made by different colleges in the same subject. With the first of these advances we are not here concerned except to express our approval. In the second we have a more direct interest, though it is not in discussion in the present paper. I take it for granted we are all agreed that science should form an integral part of the education of every individual from the kindergarten to, into and in the college, and that botany should hold among the sciences the place to which its nature entitles it. Apart, however, from the abstract merits of the case, it is a fact that some of the leading colleges of the country do now either require a science for entrance, or else will admit the sciences as options, sometimes even to the amount of one-third of their total entrance requirement. Some schools are already teaching sciences well, and under the stimulus of a wider acceptance of their results by the colleges, such teaching will unquestionably both further improve and widely spread. We cannot doubt, therefore, that the present movement is towards the general acceptance by the colleges of the sciences, with botany among them, as options, if not as a requirement, for entrance. If, in the colleges with which we are connected, the sciences, including botany, are not accepted for entrance, it should at least not be through default of vigorous championship upon our part.

It is, however, with the third advance mentioned above, namely, with the effort to secure uniformity in requirements in the same subject, that we are now immediately concerned. It is well known that the varied demands made by different colleges in the same subjects impose a most serious burden upon those preparatory schools which prepare students for several colleges, requiring multiplication of classes, division of resources, waste of energy, and, worst of all, a too great subordination of true education to preparation for the passing of examinations. This mal-adjustment of preparatory schools

as a whole to colleges as a whole constitutes one of the most serious educational problems of the present time. So serious is it that not only has the National Educational Association given its best energies for some years past to the endeavor to formulate standard national courses, but associations of colleges and preparatory schools, with large and influential membership, have been formed chiefly to grapple with it. All these efforts, be it noted, are not at all toward a uniform total requirement for all colleges, but simply toward a uniform general mode of treatment of each particular subject, and the colleges are left as free as before to make any desired permutations and combinations of subjects. The most important and practical step of all in this direction has recently been taken in the formation of the College Entrance Examination Board of the Middle States and Maryland, which is to have charge not only of the specifications of requirements in the individual subjects, but also of the uniform administration of those requirements through its own examinations. Steps have been taken, also, looking to the formation of a similar board for the New England States. Requirements have already been formulated by the former board in several subjects, but not yet in botany. Now, a question of immediate interest to us is this, what is to be the requirement adopted by these boards in botany? One would naturally expect that the course outlined by the Botanical Committee of the National Educational Association would be adopted; but this course, although embodying many good features, is not adapted, nor was it intended, for immediate practical use. If the formulation of new courses is left to the advisers of the board for the Middle States and Maryland, and to the New England Board, and to similar boards elsewhere, it is unlikely that uniformity will be secured; for such boards, like individual colleges, will not only probably be shy of accepting one another's requirements *in toto*, but also each board will be swayed by the particular views of the most prominent teacher consulted. On the other hand, a course carefully and comprehensively formulated by some central and representative scientific association, based upon the best of the previous work done in this direction, and elaborated with the cooperation of the leading teachers and of other botanical organizations throughout the country, will stand a chance of wide acceptance, and perhaps, too, is likely to be a better course than a more limited body could develop. Such a course must obviously be widely accepted in order to be of real use; but, once firmly established, it will not only permit schools to concentrate their energies upon a single and excellent method of preparation which will allow any student to enter any college and give a good education to those who do not, but also at the same time it will constitute a sort of standard of comparison and measure of value, a definite ideal towards which ambitious schools may work, and a stimulus to other colleges to adopt botany among their entrance subjects. It is the object of this paper to propose that this society undertake the formulation of such a standard or uniform entrance option in botany, and take steps to secure its adoption.

It remains now to note briefly what we have to build upon in such a formulation, what conditions must be taken account of, and what practical steps may best be taken.

The idea of a standard entrance option in botany is far from being new. It was implied in the well-known report of the Committee on Secondary School Studies of the National Educational Association (commonly known as the Committee of Ten). The recommendations of the botanical section of that committee had without doubt a powerful influence upon botanical teach-

ing in this country, and that they were not more widely adopted was due partly to the then transitional state of botanical teaching, and partly to difference of opinion as to the wisdom of some of its recommendations. The discussions of the same Association led in subsequent years to the exposition of the idea of standard entrance options, and these are set forth with the greatest clearness in the report of the committee on college entrance requirements of that Association published in July, 1899. Now, if the course in botany recommended in that report were adapted to immediate use, and if it had the approval of the majority of teachers, there would be nothing left to be done except to urge its adoption. In fact, however, whatever we may think of the merits or demerits of the course, we must all agree that it is impracticable at present for the great majority of schools. That course, with its great emphasis upon ecology, represents an extreme reaction from the old formal systematic studies, and, as is usual in such cases, the truth will doubtless ultimately be found to lie between the extremes. I had myself the honor to be consulted in the preparation of that report and gave my adherence to it as to an ideal scheme to be worked towards rather than as one to be brought into immediate practical operation. What is needed at present, however, is a course which, while setting a high and stimulating standard of intellectual work, can be brought practically and profitably into operation in the immediate future.

It will help us to understand the situation if we glance at the status of botany as an entrance subject in a few of the leading colleges. Those which follow are selected partly at random and partly because their announcements happen to be at present accessible to me, but doubtless they are fairly representative. *Bryn Mawr* requires a science, which may be botany, from all students, but the amount is small; apparently no sciences are accepted as options. *Chicago* accepts botany, a year's preparation, as a free option, counting 1 out of 15 points, and will accept 4 out of 15 points in sciences. *Columbia* accepts sciences as options up to 3 points out of 15, of which botany may count 1 point. *Cornell* accepts a science, which may be botany, as an alternative for the otherwise required mathematics. *Harvard* requires a science, which cannot be botany, counting 2 out of 26 points for entrance to the college, and will accept 7 or 8 points of sciences as options; botany, however, is accepted to count 1 point out of 21 for entrance to the Lawrence Scientific School, for which 5 points in the sciences out of 21 will be accepted as options. *Johns Hopkins* requires a science, which may be botany, but the amount required is small. *Leland Stanford* accepts 5 points out of 15 in sciences, of which botany may be one, counting 1 point. *Michigan* requires a year of physics absolutely of all students, and in addition accepts three years of science, of which botany may occupy either a year or, in combination with zoology, a half year. *Minnesota* appears to accept $5\frac{1}{2}$ points out of 15 in sciences as options, of which botany may count as $\frac{1}{2}$ or 1 point. *Nebraska* accepts 7 points in sciences out of 28 as options in one college; of which botany may count 2 points: and requires 3 points in the sciences, of which botany may be 1 point in the other college, and in the latter apparently 7 points in addition may be taken as options. *Smith* will accept the equivalent of 5 points out of 15 in the sciences as options, of which botany may count either as 1 point for a year of preparation or as 2 for two years, preparation. Of other colleges, some do not accept any sciences at all, while a few others which accept some of the sciences do not include botany among them. It appears, also, as would be expected, that the

liberal acceptance of the sciences is more common in the Central and Western than in the Eastern States.

The limits of my time will not permit even a summary of the preparation called for by the above-mentioned colleges, and it must suffice to say that this ranges from requirements little more than nominal up to some which are satisfactory in plan and scope. One characteristic which most of them show is a great liberality in the details of preparation, amounting in some cases practically to the acceptance of any good course. All this indicates a very undifferentiated condition of botanical teaching among us, a fact which, along with its many drawbacks, has at least this advantage from our present point of view, that it will be much easier to secure the adoption of a standard course than would be the case if the teaching were more differentiated. Although the preparation required appears at first sight to be very different for the different colleges, closer study shows that there are many common features, and these will form the natural and excellent foundation for the new course.

The ideal position for botany in the entrance curriculum, indeed the position towards which it seems in the most progressive institutions to be tending, is this: any college which requires any number of particular subjects should require a science; every college should accept as options enough of the sciences to allow a student thus to utilize four years of thorough high-school work in the sciences; botany should be included among these sciences; the preparation should be of such a character that it will yield a training fully equal to that afforded by any other subject studied for the same length of time, and will admit the student to second courses in college.

It will be agreed, I think, that the formulation and successful working of a standard entrance option is a matter of much importance to us. But no such course can be formulated, much less brought into use, unless all teachers approach it in a friendly and cooperative spirit, each willing to yield some of his own individual views for the sake of the common good. It must be in the nature of a compromise, though it is by no means necessary that it shall represent a composite of all existent views. It must of course be elastic enough to allow full play to individual methods and the use of any good text-books, and must be standard in its framework rather than in its details. It will of course be binding upon no one, and must make its way, if at all, by its merits; and it will be liable to minor changes in the future, based upon trial and scientific advances. Colleges would naturally first adopt it as an alternative to their own systems. Especially it should face squarely the issue of providing a course equal in training value to the other subjects, for by this test botany, and the other sciences, must be judged, and stand or fall in the educational system.

With full faith in the possibility of preparing such a course, I would ask the Society:

1. Does a standard or uniform college entrance option in botany seem desirable?

2. Does it seem possible of attainment?

If the answer to these questions is in the affirmative, I would propose:

a. That a committee of three be appointed by the president before the close of this meeting, with power to open communication in the name of the Society with colleges, examination boards and individual teachers upon this subject, and to take such steps as their judgment approves towards formulating and securing the adoption of such an entrance option.

b. That the committee make the attempt to secure an option nationally acceptable, but if this be found impracticable, then it

shall be attempted only for the region covered by the work of the College Entrance Examination Board of the Middle States and Maryland, and of the corresponding New England board if formed.

c. That the committee be authorized to draw upon the secretary-treasurer for its expenses of printing, etc., up to a limit of $20.00.

The Society voted to approve this plan with the proviso that the Committee should submit to the members by mail a preliminary printed report, and should be guided by any opinion submitted by a majority of the members. The president appointed Messrs. Ganong, Lloyd and Atkinson such a committee. The preliminary report of the committee is now ready, and will be sent to members of the Society and to others known to be interested. Others wishing to see the report may obtain copies by application to the writer. The appearance of the final report will be announced through SCIENCE.

W. F. GANONG.

SMITH COLLEGE, NORTHAMPTON, MASS.

THE MICHIGAN ACADEMY OF SCIENCE.

THE seventh annual meeting of the Michigan Academy of Science was held at the University of Michigan, Ann Arbor, March 28th, 29th, and 30th, under the presidency of Professor Chas. E. Barr, of Albion College.

The general session of Thursday afternoon, March 28th, was devoted to the geological and archeological surveys of the State. The Secretary read a paper by Mr. Harlan Smith, of the American Museum of Natural History, on 'An Archeological Survey of Michigan,' and Mr. Geo. W. Bates, president of the Detroit Archeological Society, presented a second paper by Mr. Smith, on 'The Antiquities of Michigan, Their Value and Impending Loss.' This paper described many of the archeological remains of Michigan, and urged that steps should be taken to preserve them. (At a later meeting the Academy endorsed a bill now before the Legislature, providing for an archeological survey of the State.)

Dr. A. C. Lane presented a paper (read by the Secretary) on 'Recent Work of the State Geological Survey,' and Mr. Frank Leverett, of the U. S. Geological Survey, gave an account of 'Glacial Investigations in Michigan.' These papers showed that the Government and State Surveys are cooperating, and supplementing each other's work in many respects. The State Survey is devoting itself chiefly, in the lower peninsula, to the study of marl, and to a correlation of the various coal seams; in the upper peninsula to a correlation and study of the copper-bearing lodes. Mr. Leverett's paper presented certain economic and scientific results of the U. S. Geological Survey, particularly in the mapping and interpretation of topographic features, and in variations in the structure of glacial deposits. The successive positions of the margin of the glacial ice were shown to be marked by moraines or massive belts of rolling country which are found to sweep around the basins of Lake Michigan, Saginaw Bay and Huron-Erie. These carry on their outer borders more or less extensive plains of gravel and sand, which were formed by the outflowing waters of the melting ice-sheet. The distribution of these moraines and bordering gravel plains indicates that the first counties of Michigan to be uncovered by the melting back of the ice are Branch, St. Joseph, Kalamazoo and Calhoun, and the water from the ice then flowed to the Kankakee River, past South Bend, Ind. The ice margin melted back from these counties toward the lake basins to the west and north and east, and after a time it shrunk within the present limits of the Great Lakes. The lake history connected with the present system of Great Lakes is very complicated and as yet but partially worked out.

The Academy then divided into sections of botany, zoology, sanitary science and agriculture, and sectional meetings were

held on Thursday afternoon and Friday forenoon, under the chairmanship of the sectional vice-presidents.

In the Botanical Section, Professor C. F. Wheeler, chairman, the following papers were read:

'The Perception Zone of Roots': DR. FREDERICK C. NEWCOMBE, Ann Arbor.

'Transition from Stem to Root in *Echinocystis lobata* Torr. & Gray': DR. JAMES B. POLLOCK, Ann Arbor.

'Zygomorphy of *Stylidium adnatum* R. Br.': GEORGE P. BURNS, Ann Arbor.

'Adaptation of *Solanum Dulcamara* L. to Aquatic Conditions': THERESA G. WILLIAMSON, Ann Arbor.

'Ecological Study of a Glacial Lake near Ann Arbor': HOWARD S. REED, Ann Arbor.

'Aerotropism of Roots': MAY ELLA BENNETT, Ann Arbor.

'A Disease of the White Birch': JOHN LARSEN, Ann Arbor.

'Conditions influencing the Vitality of Seeds': JOSEPH W. T. DUVEL, Ann Arbor.

'Interfoliar Scales of Monocotyledonous Aquatics': MINNA C. DENTON, Ann Arbor.

'Something concerning the Forests of Northern Michigan.' With lantern views: DR. W. J. BEAL, Agricultural College.

'Notes on the Flora of Eaton County': PROFESSOR HUBERT LYMAN CLARK, Olivet.

'The Dwarf Mistletoe in Northern Michigan': PROFESSOR CHARLES F. WHEELER, Agricultural College.

'The Relation of Algæ to Marl': PROFESSOR CHARLES A. DAVIS, Alma.

'A Noteworthy Occurrence of *Wolffia*': PROFESSOR CHARLES A. DAVIS, Alma.

'Notes on *Utricularia cornuta* Michx.': PROFESSOR CHARLES A. DAVIS, Alma.

'Notes on Michigan Saprophytic Fungi': B. O. LONGYEAR, Agricultural College.

'New Species of Michigan Fungi': B. O. LONGYEAR, Agricultural College.

'A Sclerotium Disease of the Huckleberry': B. O. LONGYEAR, Agricultural College.

'Causes inducing Asparagus to take its Form of Growth': L. LENORE CONOVER, Detroit.

In the Zoological Section, under the chairmanship of Mr. Bryant Walker, of Detroit, papers were given as follows:

'Phototaxis in Amphipods': DR. S. J. HOLMES, Ann Arbor.

'Preliminary Report on the Molluscan Fauna of the Region about Ann Arbor': MR. H. E. SARGENT, Detroit.

'Suggestions for a Method of Studying the Migrations of Birds': MR. L. J. COLE, Ann Arbor.

'The Occurrence of *Ammocœtes*, the Larval Form of *Lampetra wilderi*, near Ann Arbor': MR. D. C. SCHAFFNER.

'Some Aspects of the Electrotactic Reaction of Lower Organisms': MR. RAYMOND PEARL.

'A Curious Habit of the Slug, *Agriolimax*': MR. RAYMOND PEARL.

'The Effect of very Intense Light on Organisms': MR. RAYMOND PEARL and Mr. L. J. COLE.

'Certain Reactions of the Common Slug, *Agriolimax campestris*': MR. RAYMOND PEARL and MISS MAUDE M. DEWITT.

'Some Further Notes on the Breeding Habits of *Amia*': PROFESSOR JACOB REIGHARD.

'On the Anterior Head Cavity of the Elasmobranchs': PROFESSOR JACOB REIGHARD.

'On the Early History of the Auditory and Lateral Line Organs of *Amia*': CORA J. BECKWITH. Read by Jacob Reighard.

'The Classification of Birds': PROFESSOR HUBERT L. CLARK, Olivet.

'The Breeding Habits of Holothurians': PROFESSOR HUBERT L. CLARK, Olivet.

'Death from the Bite of the Water Moccasin, *Agkistrodon piscivorus*': PROFESSOR WALTER B. BARROWS, Agricultural College.

'Birds of the Carolinian or Upper Sonoran Zone in Michigan': PROFESSOR WALTER B. BARROWS, Agricultural College. Read by title.

In the Section of Sanitary Science, Hon. Frank Wells of Lansing, chairman, the following papers were read:

'A Bacteriological Study of an Epidemic among Guinea Pigs': LOUIS M. GELSTON, Ann Arbor.

'Frænkel's Pneumococcus found in a Case of Tonsilitis': W. G. CARHART, Ann Arbor.

'The Detection of Boric Acid in Milk': W. H. VEENBOER, Ann Arbor.

'The Detection of Formaldehyde in Milk': A. J. HOOD, Ann Arbor.

'The Toxin of the Colon Bacillus': DR. V. C. VAUGHAN, Ann Arbor.

'Some Results of Public Health Work': HON. FRANK WELLS, Lansing.

'Biological Problems in the Prevention of Certain Diseases': DR. HENRY B. BAKER, Lansing.

In the Section of Agriculture, J. A. Jeffery, chairman, Dr. W. J. Beal gave a

paper on 'Some Relations of Botany to Agriculture,' and Mr. Kenyon Butterfield gave a talk on 'Some New Phases of Agricultural Education.'

On Friday afternoon a joint session of the Academy and the Biological Section of the Michigan Schoolmasters' Club was held in the University Museum. This session was largely devoted to the pedagogical aspects of the biological sciences. The papers given were as follows:

'Nature Study.' Presidential Address: Professor Charles E. Barr, Albion.

'How Shall a Young Person Study Botany?' Dr. W. J. Beal, Agricultural College.

'Outline for a Year's Work in Botany': L. Lenore Conover, Central High School, Detroit.

'Suggestion for a Year in Zoology': Miss André, Central High School, Detroit.

'Value of Supplementary Experiments': Dr. Lewis Murbach, Central High School, Detroit.

'Science in the High School': Miss Palmer, High School, Lapeer.

'Recent Work and Theories on Fertilization of Animals': Dr. S. J. Holmes, Ann Arbor.

'Recent Work and Theories on Fertilization of Higher Plants.' Illustrated by Lantern Slides: Dr. J. B. Pollock, Ann Arbor.

'The Proposed Topographic Maps of Michigan': Dr. Israel C. Russell, Ann Arbor.

Two evening lectures were given before the Academy. On Thursday evening, Professor H. S. Carhart of the University of Michigan lectured on 'The Place of Physics in a Liberal Education,' and on Friday evening, Professor F. H. Herrick of Western Reserve University gave an illustrated lecture on 'The Haunts and Habits of Wild Birds.'

At the business meeting Saturday morning a committee was appointed to confer with corresponding committees from other scientific societies of the State, with a view to the affiliation of the other scientific bodies of the State with the Academy. The Academy voted also to endorse the bill now before the Legislature for an archeological survey of Michigan. The following officers were elected for the coming year:—

President, Professor Victor C. Vaughan, University of Michigan; *Vice-President*, for Botany, Professor C. F. Wheeler, of the Michigan Agricultural College; for Zoology, Professor Hubert Clark, of Olivet College; for Sanitary Science, Hon. Frank Wells, Lansing; for Agriculture, Professor J. A. Jeffery, of the Michigan Agricultural College; *Treasurer*, Professor Wm. H. Munson, Hillsale College; *Secretary*, Dr. James B. Pollock, University of Michigan.

A considerable number of new members were elected at this meeting; the sessions were well attended, and great interest was manifested in the work of the Academy. Altogether the meeting was the most successful and interesting in the history of the Academy.

H. S. Jennings.

SCIENTIFIC BOOKS.

Traité d'astronomie stellaire. Par Ch. André. Directeur de l'observatoire de Lyon. *Première partie: Etoiles simples.* 1899. Pp. xvi + 344. *Deuxième partie: Etoiles doubles et multiples. Amas stellaires.* Paris, Gauthier-Villars. 1900. Pp. xxiv + 429.

This excellent work seems to have attracted less attention than it deserves. It has the distinction of filling a gap in the literature of the subject. It covers ground which is common to both astrophysics and astronomy of position, as treatises are now more and more compelled to do; for in spite of the increase of specialization, the distinction in results obtained by astrophysical and astronomical methods is becoming slight. What, for instance, is an essential difference between the two components of the actual linear motion of a star, although the one is determined purely by the processes of astronomy of position, while the other is measured by the spectroscope?

The opening chapter of Professor André's first volume deals with objectives and mirrors, a topic upon which he is especially well fitted to speak. The sections treat of the theory of optical images, of the effect of diffraction screens or diaphragms over the objective, and of images

of the sun and planets. Chapter II. gives a general description of the constellations and a discussion of the various star catalogues and charts since the time of Hipparchus. The next two chapters deal with stellar magnitudes, referring particularly to determinations of brightness made without instrumental means. The number and distribution of the stars, and a study of the Milky Way occupy two chapters.

The proper motion of the sun and the various methods of determining the apex of the sun's way are next considered, and this is naturally followed by the proper motions of the stars. An especially interesting table is that giving a comparison of the radial velocities with the proper motions on a great circle for fifty of the brightest stars. Chapter IX. treats of stellar parallaxes, giving the results obtained by many investigators. The volume closes with a chapter of 50 pages on variable stars.

The orbits of binary systems and the various methods of their calculation (Herschel, Kowalsky and Glasenapp, Zwiers) are discussed at considerable length, together with their number and dimensions, in the opening chapters of the second volume. A table is given containing the elements of sixty-six known orbits. The effect of the introduction of a linear element, the radial velocity, is treated in one of the sections, and M. André has calculated for the sixty-six well-established binaries the epochs at which a maximum radial velocity may be expected, and the value of that maximum on the assumption of a stellar parallax of $0''.2$. 'Astronomy of the Invisible' is the title of a chapter of 37 pages, dealing chiefly with the orbits of *Sirius*, *Procyon*, ζ *Cancri*, and 70 *Ophiuchi*.

The methods of Rambaut and Lehmann-Filhès for computing the orbits of spectroscopic binaries are given in sufficient detail in a separate chapter. About one hundred and thirty pages are next devoted to 'photometric binaries.' This includes a full historical account of *Algol* and its investigation by Pickering, Harting, Vogel, Chandler and Tisserand, together with all available data as to seventeen other variables of the Algol type. Dunér's beautiful work on the orbit of Y *Cygni*, published last spring in the *Astrophysical Journal*, was unfortunately too late to be included.

Subsequent chapters treat of the clusters and nebulæ, in particular of the *Pleiades*, *Præsepe*, and the region of η *Carinæ*; of the distribution of these objects, and of their distance. Globular clusters have a chapter of their own, which includes Bailey's recent remarkable variables. A short chapter is also given to colored stars.

The two volumes contain over one hundred cuts, and three excellent plates, and are printed in the usual excellent manner of Gauthier-Villars. A rather large list of errata is given, and probably more will be found. The book abounds in examples of the characteristic French disregard of the correct spelling and initials of foreign proper names.

This somewhat detailed account of the scope and contents of the work has been given to justify the remark that it fills a gap in the literature of the subject. The book would seem to be very well adapted for a basis of an elective course for seniors in our colleges, and the subjects treated are surely of greater freshness and interest, and of no less value in mental discipline, than the customary courses on the orbits of comets and planets.

A third volume is promised to complete the work—on the methods and instruments of modern research, and on the formation and evolution of the universe.

EDWIN B. FROST.

The Steam-engine Problem. By S. H. BARRACLEUGH, B.E. (Sydney), M.M.E. (Cornell). Russell School of Engineering, University of Sydney, N. S. W. Sydney, Kealy and Phillip. 8vo. 1900. Pp. 47. Figs. 13.

In this little book of less than fifty pages, Professor Barracleugh admirably outlines the problem of the steam-engine as it is now coming to be enunciated by scientific engineers and by thermodynamists who recognize the fact that the thermodynamics of the ideal may not constitute all, and that the real engine offers a complex problem which involves the most abstruse studies in physics, mechanics and energetics. This outline originally appeared in substance in the *Australian Technical Journal*. It was

written for students having an elementary knowledge of the subject.

The plan of the book includes a statement of the problem, its financial aspect, its mechanics, the scientific side and the practical side as well. The scope of the problem, choice of site, character of installation, type of engine and boiler, and their design, construction, erection and operation, are excellently stated, including the finance of the case. Finance is taken as the controlling factor, and the costs of steam-power are indicated and illustrated. Rankine's method of apportioning the engine to its work, as a financial proposition, is described, its fatal defect shown, and the later and corrected system of use of true 'curves of efficiency' is described. In designing, the method of Professor Barr of ascertaining the results of general experience in determining the factor of safety is described and its results given.

A brief and well-arranged statement of the fundamental principles of thermodynamics is presented and an excellent outline of the scientific side of the problem is laid down. The great defect of the real engine, its internal waste of heat and steam, is well described, as are the results of later investigations to determine its amount and its laws of variation.

R. H. Thurston.

Catalogue of the Fossil Bryozoa in the Department of Geology, British Museum (Natural History). By J. W. Gregory. The Cretaceous Bryozoa, Volume I. London, Longmans & Co. 8vo. Pp. 457. 17 pl.

The long list of British Museum (Natural History) catalogues has received another welcome addition in the Catalogue of the Cretaceous Bryozoa, Volume I., by Dr. J. W. Gregory.

This catalogue is devoted entirely to descriptions and figures of the Cretaceous bryozoa, the groundwork, terminology, classification, etc., having been laid by the author in an earlier work of the same series: The Catalogue of the Jurassic Bryozoa in the British Museum (Natural History), published in 1896. In a second volume, to appear later, the author hopes to give a general introduction to the Cretaceous bryozoa, a list of localities with their horizons, and a bibliography. The catalogue is intended to be complete, to include every recorded species, though the large number of inadequate descriptions by early writers and their unrecognizable figures will leave much in doubt. It is a question whether science would not be a gainer if much of this early work could be authoritatively set aside. The desire to conform too strictly to the law of priority or to do justice to early workers sometimes results in even greater injustice to later workers.

The present volume treats only of the Cyclostomata. This division Dr. Gregory raises to ordinal value and divides into the suborders: Tubulata, with the families Diastoporidæ, Idmoniidæ, Entalophoridæ, Eleidæ; Cancellata, with families Horneridæ, Petaloporidæ; Dactylethrata, with families Clausidæ, Terebellariidæ, Reticuliporidæ.

The large size of the present volume is itself evidence of the fine collection which the British Museum has accumulated. The author notes the large additions recently made to the collection and laments that an American collection was received too late to be included in this volume. Doubtless the second volume will supply the deficiency. No work of importance has been done on bryozoa from secondary and tertiary formations of America since the work of Gabb and Horn in 1860–62. The interesting bryozoan fauna of the Cretaceous marls of New Jersey has begun, however, to attract the attention of workers in this country as well as abroad.

The greatest of the many merits of the volume under consideration is the great care taken in collecting full synonymy and in giving careful, accurate descriptions with measurements. The rather complicated mode of relative measurements which the author employed in the volume on the Jurassic bryozoa he has abandoned for the simpler and more easily comprehended plan of absolute measurements. We believe the author adopts the correct position when he says that dimensions, while important, seem to him of far less value than is attached to them by some continental writers, who make them the chief specific distinctions. It is no doubt true that, in some groups, each species is very constant in its dimensions, while in other groups species are very variable in this respect. But the same is true of other charac-

ters; a character which is constant and therefore reliable for purposes of differentiation and classification in one suborder or family, in another may be highly variable. This fact must be recognized in framing classifications.

The author retains with a few minor changes the classification proposed in the catalogue of the Jurassic bryozoa. In the present state of knowledge some scheme of classification is a necessity and yet but a temporary expedient. Our knowledge of the derivation, purpose, function and relative importance of the various structures found in fossil bryozoa is still too imperfect to enable an abiding classification to be framed. After all, the main purpose of a classification is to provide a scheme for maintaining an easy grasp upon relationships.

At the present time the best work that can be done is just the kind which our author does in this work, the giving of careful, close, accurate description with some account of the variations exhibited by a 'species,' with figures from which the form can be certainly recognized, and the careful, accurate, critical examination of the literature to weed out the synonyms. The author describes a considerable number of new species, showing that even in this direction there remains a great deal to be done. To the student of the bryozoa in general and the Cretaceous bryozoa in particular, the present volume must prove an indispensable working requisite.

J. M. N.

The Human Nature Club; An Introduction to the Study of Mental Life. By EDWARD THORNDIKE, Ph.D. Longmans, Green & Co. 1901. 8vo. Pp. 235.

This is an attempt to present the main facts of psychology in the form of a story, or at least of dialogue. Of this aspect of the essay the author says: 'Dramatically it is an atrocity.' Such frank disclaimer makes any further comment ungracious. And yet it would certainly have added much to the success of the undertaking not to have so entirely ignored the artistic factor in the presentation. It must, however, be viewed merely as a pedagogic aid to the popularization of the study of psychology, and particularly as a means of arousing interest in the significance of the every-day mental life among every day people. As such it is an eminently sound and helpful presentation. It is also more than this, as it presents a perspective of the importance of some of the factors of mental assimilation, which bear the mark of close and original thinking. This is particularly true of the discussion of the formation of habits, with reference to the effect of special upon general training. In the main it is an appropriately eclectic treatment of the primary elements of our mental nature. The Human Nature Club is a very artificial assemblage of persons, who discuss, with rare singleness of purpose, 'what the brain does,' and the 'things we do without learning' and 'the different ways of learning'; consider the senses and memory and attention and trains of thought and mental imagery and suggestion and imitation and our emotions and our actions and character, and some other yet more complex and deeper questions. Socrates would certainly be shocked at the modern speed with which conclusions are drawn from a few sporadic, and yet significant, illustrations, with but little allowance for analysis or dialectic. But this is inevitable, if the book is to cover its ground; and after all, the characters of the dialogue do not really draw these conclusions, but only restate them from such worthy authorities as James and others. The psychological matter is well grounded, suggestive, discriminatingly used and clearly set forth. The query will arise with reference to the proof of the pudding, which according to modern notions is not in the eating, but in the digestion thereof. That the book may prove palatable to certain palates, it is easy to believe; but whether persons with sufficient maturity of mind to consider psychological questions at all should not be at once placed on more strenuous diet, is a question upon which teachers of psychology are likely to hold diverse opinions. Yet with whatever training they may desire their pupils to approach the study of mental phenomena, it would be mere perversity to fail to recognize that there is in this country a large class of persons who do 'study' psychology, are genuinely interested, and are likely to be approachable only by ap-

propriate popularizations. For these this volume has the promise of proving serviceable, and to others and more serious students it may not be without suggestive value. It is fortunate, at all events, that the psychology thus presented draws its inspiration from worthy and scholarly sources, and is presented in a way calculated to make the student think and observe, not merely read and repeat. We may question whether good wine should be so much diluted; but however thin, it retains a flavor which wine of lesser quality never bears.

SCIENTIFIC JOURNALS AND ARTICLES.

NUMBER LI. of the *Journal of American Folklore*, which is late in appearing, and concludes the year 1900, contains as the first article a Hawaiian legend entitled 'Laieikawai,' from the memoranda of Dr. John Rae, by whom the story was taken down and translated, probably about 1860. Of this narrative a variant appears in the book of King Kalakaua, published in 1888. Both versions are abstracts, but the account of Rae, which is only a fragment, is so far as it goes much fuller, and gives a much better idea of the literary character of Hawaiian myth than any other accessible source of information. The story seems to have been a prose epic narration of great length, ornamented with occasional pieces of verse and provided with a very complicated plot. The state of society, and the conceptions as well as modes of expression, frequently remind the reader of the Homeric poems. The heroine from whom the tale is named was worshipped by certain Hawaiian gentes under the title of the Lady of the Twilight, and the sun-hero became her husband. The story of Rae recites the manner in which the girl, as born before the coming of a brother, is sentenced to be put to death, her concealment by her grandmother, education in a cave below a waterfall, growth to maturity, and great beauty, the fame of which got abroad, and caused a quest after her place of hiding, which was indicated by the presence of a rainbow, attendant on the maiden as of divine race. The narration is full of information concerning Hawaiian cult and superstition, and makes a valuable addition to the existing stock of knowledge. It is to be hoped that the publication may lead to a determined attempt to preserve Hawaiian legendary lore, and to procure full and correct texts in the original language. Miss A. C. Fletcher describes a Pawnee ceremony of thanksgiving, at which she had the good fortune to be present. In this rite a buffalo skull was worshipped as representative of an ancient divine buffalo established by the supreme deity Tirawa as mediator and teacher of men. Dr. A. F. Chamberlain contributes a discussion on 'Algonkian Terms connected with Religion and Mythology.' Among the items of belief may be noted evidence that sacrifices were made to the war-god by the suspension to trees of human victims; one is reminded of the similar Norse offerings to Odin. Rev. W. M. Beauchamp supplies an Onondaga tale of the Pleiades, in which these stars are represented as merry children who have danced themselves into the sky. The excellent record of 'American Folk-Lore' is continued by Dr. A. F. Chamberlain (Clark University, Worcester, Mass.). With the present year Dr. Chamberlain will assume the general management of the journal, Mr. W. W. Newell, who has hitherto

fulfilled that function, remaining as associate editor.

In a reprint of articles on early American ballads, contained in Nos. 47 and 49 of the same *Journal*, Mr. W. W. Newell traces the history of certain ballads produced in Massachusetts. One of these, called 'Isaac Orcutt,' and belonging to the end of the eighteenth century, recited the manner in which that youth met his death from a falling tree; the piece was sung as a dirge at the funeral, being chanted by six young women dressed in white. Similar was the origin of 'Springfield Mountain,' produced in 1761, in memory of the son of a Lieutenant Merrick, of Wilbraham. The ballad attained extraordinary popularity in the United States, being sung with numerous variations; it abdicated its local character, took on a love situation, and survives as a comic song. These examples are the more curious inasmuch as the custom of chanting dirges over the dead seems not to be recorded in English folk-lore.

The Popular Science Monthly for April opens with a sketch of the work of 'Malpighi, Swammerdam, and Leeuwenhoek,' by William A. Locy. Paul H. Hanus discusses 'Two Contemporary Problems in Education,' What shall we do about the elective system of studies and how shall we bridge the gap between the high school and the lower grade? Incidentally Professor Hanus advocates studying some modern language for two or three years before commencing Latin. Havelock Ellis continues 'A Study of British Genius,' this instalment being devoted to heredity and parentage, and the favorite topic of 'Suicide and the Weather,' is treated in some detail by Edwin G. Dexter. Charles H. Cochrane gives a résumé of 'Recent Progress in Aërial Navigation,' and 'The Foreign Trade of the United States,' is treated at some length by Frederic Emory, who, while noting its recent great increase, calls attention to the fact that in the near future we may be obliged to struggle to retain it. Finally Solon I. Bailey tells of 'The Planet Eros,' which for various reasons, among them its importance for determining the solar parallax, is for the moment of more interest to the astronomical world than the greatest planet. The various departments contain articles of interest and the number contains the index for Vol. LVIII.

SOCIETIES AND ACADEMIES.

SECTION OF BIOLOGY OF THE NEW YORK ACADEMY OF SCIENCES.

At a regular meeting of the section held on March 11, 1901, the following program was offered:

H. F. Osborn: 'Systematic Revision of the American Eocene Primates and of the Rodent Family *Mixodectidæ*.'

O. P. Hay: 'The Composition of the Shell of Turtles.'

M. A. Bigelow: 'Some Comparisons of the Germ-Layers in Entomostraca Crustacea.'

Professor Osborn stated that the only fossil primates at present known are those in the Eocene. The supposed Oligocene genera described by Marsh and Cope have proved to belong to the Artiodactyla. Associated throughout with the discovery and literature of the primates is the family Mixodectidæ, including *Mixodectes* of the basal Eocene or Torrejon beds; Mathews has suggested that this animal is a rodent. Careful comparison of this type with the supposed primates *Cynodontomys* of the middle Eocene and *Microcyops* of the upper Eocene proves that these animals also belong probably with the rodentia; they represent a primitive stock with strong affinities to the Tillodontia, which are thus brought nearer to the ancestral rodents. This conclusion removes all these animals from the primates where they have hitherto been placed. This leaves three families of monkeys, as follows: Hypsodontidæ, including *Hypsodus* and *Sarcolemur*, animals of medium size, retaining the typical series of 44 teeth; a second family, the Notharctidæ, including *Pelycodus* and *Notharctus*, animals of larger size, with teeth reduced to 40 by the loss of 4 incisors, and like the foregoing comprising long-jawed types; and a third family, the famous Anaptomorphidæ of Cope, short-jawed, very progressive types, with 36 to 32 teeth, the premolar series being reduced. The identification of these families with the Eocene *Adapidis* or with *Necrolemur* of Europe is not sustained. The Hypsodontidæ and Notharctidæ are well

distinguished by sexituberculate superior molars.

Dr. Hay called attention to the fact that for a long time there has been much discussion regarding the origin of the elements entering into the shell of turtles. As to the bones known as costal plates, the great majority of anatomists have held that they have resulted from the union of dermal bones with underlying ribs: the neural plates from the union of dermal bones with the neural arches. Recently Goette has studied the development of the costals and neurals in the young of *Chelone squamata*. He finds that the whole costal plate develops continuously from bone which appears beneath the perichondrium of the cartilaginous ribs. No part of either the costal or neural plates arises in the skin. While accepting Goette's results as established, the speaker did not accept his conclusion. Neither did he accept the other view that the costals and neurals are composed of dermal bones united with those of the internal skeleton. The speaker held that there were originally three strata of bones on the dorsal surface of turtles. One of these was in the skin, and is represented by the mosaic found in the skin of *Dermochelys*. Another layer was sub-dermal, and this united with elements of the third stratum, namely the ribs and neural arches. This union has become so complete that the bones arise from the same centers. These three strata of bones on the dorsal surface correspond to those which are found in the ventral wall of the caiman, viz: true ribs, 'abdominal ribs,' and bony dermal scutes.

Mr. Bigelow compared the germ-layers of various Crustacea with special reference to the Cirriped *Lepas*. It was pointed out that in the cleavage leading to the segregation of the germ-layers there are very many resemblances between *Lepas* and other Entomostraca. *Lepas* resembles most other Crustacea in respect to the position of the blastopore, and the extension of the entoblast and mesoblast from that region as a starting point. In *Lepas* also the mesoblast and entoblast originate from cells which, speaking in general terms, lie at first in the blastoderm and later migrate into the cleavage cavity. But among these immigrating mesentoblastic cells one can distinguish the individual cells of entoblast and two varieties of mesoblast, entomesoblast and ectomesoblast. There are observations indicating that similar conditions exist in other Crustacea.

HENRY E. CRAMPTON,
Secretary.

SECTION OF ASTRONOMY, PHYSICS AND CHEMISTRY OF THE NEW YORK ACADEMY OF SCIENCES.

A REGULAR meeting of the section was held on April 1, 1901. The first paper was by Mr. H. C. Parker, on some 'Experiments on Standards of High Electrical Resistances.' The author briefly described the usual methods employed in the measurement of high resistances and then gave an outline of Professor Rood's electrometer method (*American Journal of Sciences*, Vol. X., October, 1900, pp. 285–294). By this method it seems possible to measure resistances as great as 1,000,000,000 megohms, while by the direct deflection method the practical limit was stated to be about 100,000 megohms.

The author gave the results of a series of measurements made on a new form of standard high resistance, devised by Professor Rood. This form of standard consists of oxide of manganese on cobalt glass. It gives a convenient means for obtaining resistances of from one to ten thousand megohms. Most of the measurements were for the purpose of determining the best protective insulating material with which to coat the above resistances. The author stated that the work was still in progress.

Professor J. K. Rees then presented a paper on 'Temporary Stars, with Especial Reference to the New Star in Perseus.' Professor Rees explained the present classification of variable stars and gave illustrations of each of the six classes. A history of the discovery of the new star in Perseus was given and photographs of its spectrum were exhibited. Brief mention was made of the various collision theories proposed to account for the evidence of two light sources which appear involved. The light curve of the new star was referred to, showing how rapidly the star increased to the 0 magnitude,

from which it has slowly decreased to, at present (April 1st), the 5th magnitude.

The paper was discussed by Professors Hallock and Herring, Dr. Day, Mr. C. A. Post and others.

Professor Rees then gave 'An Exhibition of some of the Photographs of Nebulæ taken with the Crossley Reflector of the Lick Observatory,' by the late director, J. E. Keeler. Professor Rees remarked that Columbia University had lately received a series of beautiful photographs of nebulæ from the director of the Lick Observatory. After a brief description of the Crossley reflector, and of the remarkably successful work of Dr. J. E. Keeler in the photographic study of nebulæ, the illustrations named below were thrown upon the screen.

Orion nebula, taken November 16, 1898; exposure, forty minutes.

51, M. Canum Venaticorum, taken May 10, 1899.

Dumbbell nebula in Vulpecula, taken July 31st, 1899; exposure, 3 hours.

Trifid nebula in Sagittarius; exposure, 3 hours.

The Pleiades, showing nebulosity.

Ring nebula in the Lyra.

Crab nebula in Taurus.

Small nebula in Andromeda.

Spiral nebula M. 74, in Pisces.

Spiral nebula in Pegasus.

Spiral nebula in Triangulum.

Spiral nebula in Ursa Major.

Net work nebula in Cygnus.

M. 13, in Herculis, star cluster.

Reference was made to Keeler's determination of radial velocities of nebulæ and to the distances of these masses. In conclusion an enthusiastic tribute was paid to the late Director Keeler.

F. L. TUFTS,
Secretary.

THE ONONDAGA ACADEMY OF SCIENCE.

At the regular monthly meeting held at the Medical College, Syracuse, N. Y., on February 15th, Dr. L. M. Underwood, of Columbia University, New York, addressed the Academy on the subject of 'Botanical Gardens.' His paper was a history of the great Botanical Gardens at Kew, Java, Berlin, etc., together with a description of the Gardens planned for New York in connection with the University. The address was very fully illustrated with a fine collection of slides.

The following officers were chosen for the ensuing year: *President*, Dr. W. M. Beauchamp; *Vice-President*, Dr. C. W. Hargitt; *Corresponding Secretary*, Philip F. Schneider; *Recording Secretary*, Horace W. Britcher; *Treasurer*, Miss L. W. Roberts; *Librarian*, Mrs. L. L. Goodrich.

On March 15th, the meeting was held at the Historical Rooms. The program consisted of the reports of the officers and sections for the year.

Mr. C. E. Wheelock read the report of the Geologic Section giving a detailed account of the various meetings and conferences. Two new cephalopods, undescribed as yet, were reported from the Goniatite Limestone, making seventeen organisms discovered in this formation.

Mrs. L. L. Goodrich read the report of the Botanical Section. Monthly meetings and weekly classes are held. At one of these meetings on the grounds of the Hon. C. E. Smith, Syracuse, a hybrid chestnut tree, which he had raised, was seen, upon which over a hundred humming birds had congregated to gather honey, a truly remarkable sight. Three new plants, one a fern, have been added to the list from this county. The ferns now number 41.

Dr. C. W. Hargitt gave the report of the Zoological Section. During the past year they have been working largely upon the lower forms, especially the bacteria, of local streams. Variations in local shells have also been recorded. Three new batrachians and 25 spiders have been added to lists from the county, and cyclops and branchippus described and identified.

The annual report of Secretary E. M. Pattee showed 40 active, 17 associate and 3 corresponding members. It also recorded the loss by death of Professor J. A. Dakin, the noted ornithologist, during the year. Miss L. W. Roberts, treasurer, reported a balance of $87. Dr. Wm. M. Beauchamp, president-elect, then read his inaugural address. It was a clear and scholarly address, carefully defining his posi-

tion, and teeming with helpful suggestions and plans for the year.

Philip F. Schneider,
Corresponding Secretary.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

At the meeting of the Academy of Science of March 18, 1901, forty-three persons present, Professor E. H. Keiser delivered an address showing the progress made in the science of chemistry during the nineteenth century. This address will be published in a subsequent number of Science.

Professor F. E. Nipher exhibited pieces of pine board a foot square, showing the tracks of ball lightning discharges upon them like those formerly described by him in No. 6, Volume X., of the *Transactions* of the Academy. The discharges formerly described had been formed on a photographic film. The balls were very small, and wandered over the plate, leaving a track of metallic silver in their wake. In the present instance the balls were much larger, and they burned a deep channel in the wood. They are formed at the secondary spark gap of a coil. The terminals are pointed and are under control, so that the gap may be changed in length. To start the balls, the pointed terminals are put upon the wood surface, so near that the spark carbonizes somewhat, after which the gap is made longer. These balls travel in either direction, when a direct current is used, with a Wehnelt interrupter. This differs from the results reached on the photographic film with the Holtz machine. There the balls came from the cathode. Even when they originated at isolated points on the film, they traveled away from the cathode.

In the present results, the balls have been caused to originate at isolated points, and two balls have started in opposite directions. Wood which gives little flame shows the phenomenon to best advantage, but the balls preserve their identity and travel slowly along even when completely surrounded by flames of the burning wood.

Three persons were elected to active membership in the Academy.

William Trelease,
Recording Secretary.

DISCUSSION AND CORRESPONDENCE.

RESIGNATIONS FROM THE SCHOOL OF PEDAGOGY, NEW YORK UNIVERSITY.

Owing to long-continued dissatisfaction with the administration of the Department, the following professors of the faculty of the School of Pedagogy of New York University announce their resignation from the University:

Samuel Weir,
Professor of History of Education and Ethics.

Edward F. Buchner,
Professor of Analytical Psychology, and Secretary of the Faculty.

Charles H. Judd,
Professor of Experimental Psychology.

THE PROPER NAME OF THE ALPINE CHOUGH.

To the Editor of Science: I should like to state the reasons why I cannot agree with Mr. W. J. Fox's proposal made in Science for February 8 (N. S., Vol. XIII., p. 232) to adopt the name '*Monedula pyrrhocorax*' for the Alpine chough. In the first place, as Mr. Fox allows, Hasselquist's '*Iter Palastium*,' being dated 1757, has no claim to recognition, even by those who take Linnæus's tenth edition (1758) as the commencement of zoological nomenclature. It seems to me, therefore, that the mere republication of his names in a German translation of that work in 1762 is not sufficient to give them validity. But what is still more important is that, as Mr. Fox will find, I think, on reading the original description carefully, it is by no means certain that Hasselquist's *Monedula pyrrhocorax* was based on a specimen of the Alpine chough, though it was referred to that species by Linnæus in his edition of 1758. Hasselquist gives 'Lower Egypt' as the place where his *Monedula pyrrhocorax* was discovered, but, according to the best authorities (see Schelley's 'Birds of Egypt,' p. 161), no such bird as the Alpine chough is known in Egypt, and it is indeed a very unlikely species to occur there, though it is found in the high rocky mountains of Algeria. Under these circumstances I maintain that we should not be justified in changing the familiar name *Pyrrhocorax alpinus* to *Monedula pyrrhocorax*.

P. S. Sclater.

3 Hanover Square, London, W.,
March 15, 1901.

NOTES ON INORGANIC CHEMISTRY.

ATOMIC WEIGHT STANDARD.

In spite of the all but unanimous decision of the International Committee on Atomic Weights, that the standard should be Oxygen = 16, the question seems not yet to have been finally settled. At the December meeting of the American Chemical Society, a report was presented by the section of the International Committee appointed by the Society, in which it is shown that opinion is still somewhat divided, and an expression of views is called for from the members of the Society. For the guidance of the members a very fair statement is made in brief of the principal arguments for both standards. According to the report, Professor Erdmann writes that out of 143 replies to the teachers' circular, 118 favor the retention of the old standard, Hydrogen = 1. It will be remembered that after the report of the International Committee, six German chemists sent out a circular to the teachers of chemistry in German universities and technical schools, advocating the old standard, and calling for expressions of opinion. It is natural that replies to this *ex parte* circular should have been chiefly received from those who agreed with its views, but the number of favorable replies indicates that there is an element, by no means small, who are opposed to the majority. It is, however, not the teachers alone who are to be considered in this matter; the selection of the standard of atomic weights is of at least as much importance to the practical chemists, who vastly outnumber the teachers.

In the opening number of the *Berichte* for the year, the section of the International Committee representing the German Chemical Society publish the annual table, headed 'Internationale Atomgewichte. O = 16.00,' but they also print a second table with the heading 'Didaktische Atomgewichte. H = 1.00,' with the comment that it is done for those teachers who cannot reconcile their teaching to a standard which is anything other than unity. It is interesting to note that in this table appear for the first time gadolinium, krypton, neon, thulium and xenon, which are thus given a final standing as elements.

In reviewing these tables in the *Zeitschrift für anorganische Chemie*, F. W. Küster reproduces the report in full, except that he omits the second didactic table, as unnecessary for the readers of the *Zeitschrift*. He says the only end gained by printing it would be to keep up the discussion, which should now be looked upon as finally settled. On the other hand, it would seem that in the end unanimity is far more likely to be obtained by still allowing the freest discussion, rather than by suppressing it, while any considerable number of chemists, including some of the most eminent, refuse to acquiesce in the decision.

ACTION OF ALCOHOL UPON METALS.

Some time since, a note was made in these columns of a specimen of alcohol contaminated with zinc, which could only have come from its being kept, as is so often the case, in a galvanized iron container. The subject has been more recently investigated by Dr. Malméjac, and his results published in the *Journal de Pharmacie et de Chimie*. In his experiments he used ninety-five-per-cent. alcohol which left no residue on evaporation. The metals, copper, iron, tin, lead, zinc and galvanized iron, were corked up with the alcohol in glass flasks, and kept at ordinary temperature for six months. The copper was entirely unacted upon, but in all the other flasks there was a deposit at the bottom, and the metal was covered with a similar deposit. In the case of tin, lead, zinc and galvanized iron, the deposit was white; that from the iron was red, resembling iron rust. All the liquids, except that in which the lead had been placed, filtered clear; the latter retained its milky appearance after repeated filterings through double filters. The clear filtrates from iron, lead, zinc and galvanized iron gave much residue on evaporation, while the residue from tin was hardly appreciable. In the former cases it is clear that not only had the metal been oxidized, but a considerable quantity had entered into solution. These experiments have an important bearing on the preserving and shipping of alcohol, especially in view of the fact that absolute alcohol is very generally purchased in galvanized iron cans. In such a case redistillation is imperative.

J. L. H.

CURRENT NOTES ON PHYSIOGRAPHY.

THE ILLINOIS GLACIAL LOBE.

THE elaborate monograph by Leverett on 'The Illinois Glacial Lobe' (Monogr. XXXVIII., U. S. Geol. Surv., 1899, xxi + 817 p., 18 maps, 6 pl. 9 figs.) has, apart from its high worth as the most detailed study of its kind yet published, a great value to the physiographer in warranting a generic treatment of the class of forms that it describes. It is not merely that one may find, in this or that part of Illinois, till plains, moraines, loess beds, gravel trains and the like, but that these several parts have a form and distribution characteristic of their class. Since Chamberlin's recognition of the lobate margin of the glacial sheet indicated by the peculiar arrangement of its terminal moraines, evidence in great variety and quantity has been discovered to confirm his generalization; and we have now come to possess good ground for regarding the moraines and the associated deposits and erosion forms of lobate ice sheets as characteristic elements of our topography, on a large scale horizontally, although of small vertical relief. The type form is relatively simple; it consists of many parts, but they are systematically and genetically related in a highly specialized unit; a unit whose empirical description is as baffling as would be the mention of an oak tree in terms of its items in arbitrary order instead of by its generic or specific name, but whose explanatory description is as easily apprehended as is that of a mature river-and-valley system. The association of several units by repetition of process provides something of the variety of nature; special features due to local conditions require an elastic instead of a rigid conception of the type; and the detection of the changes suffered by the initial forms with the passage of time affords a pleasing exercise for observation and understanding. An abstract of the facts thus understood, with Illinois as the field of their typical occurrence, should enter the high schools of this generation. Room may possibly be provided for them (by the exclusion of less worthy matter) in the grammar schools of the next generation. A closer study of the facts affords good exercise for collegiate students who have previously learned an outline of them in school. The details yet to be discovered in the field will tax the patience and ingenuity of the investigator for years to come. The monograph is a worthy monument to the skill of the observer who executed it, to the insight of the leader who planned it, and to the broad policy of the organization that supported its preparation and publication.

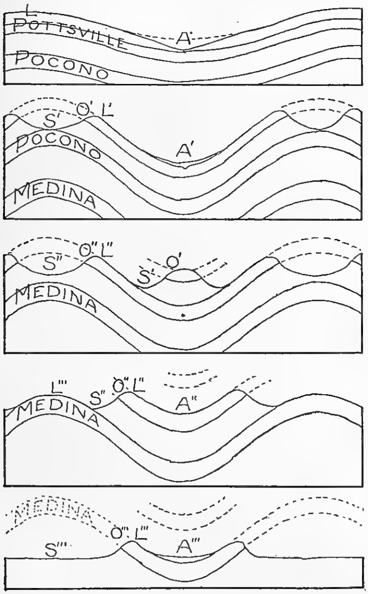
THE ALBAN MOUNTAINS.

THE group of extinct volcanoes southeast of Rome, sometimes known as the Alban mountains among English writers, but called *Vulcano Laziale* by the Italians, is elaborately described by Sabatini (Mem. descr. Carta geol. ital. X, I Vulcani del l'Italia centrale e i loro prodotti. Parte I., Vulcano Laziale. Roma, 1900, pp. xv + 392, 9 pl., 2 maps). The mountain group is the complex product of successive constructive and destructive actions. A large volcano of about 20 kil. diameter lost its upper portion and then remained as a horseshoe mountain (caldera) now somewhat dissected and open to the southwest. Its central floor had an altitude of 400 or 500 met., and its rim, of 600 to 800 met. This structure is called *Cratere Tuscolano*. A second volcano, called Monte Albano or Laziale, was built on the same axis as the first; its basal diameter being 4.5 or 5 kil., and its altitude 956 met. It has a crater 200 met. deep, open to the northwest. At a still later time, three more or less complex basins or calderas were formed on the south and southwest of the central axis; they now contain lakes Nemi and Albano, of which some admirable views are given, and the plain of Ariccia. Lavas seem to constitute only a small portion of the volcanic mass. Its chief constituent is tufa, which Sabatini explains as successive deposits of volcanic ashes washed by rains, disregarding their suggested origin in torrents of mud ejected from the craters. Engulfment is not accepted as a satisfactory explanation either of the great *Cratere Tuscolano* or of the lake basins, but the argument for the exclusion of this process does not seem demonstrative. The volume of ejected materials is estimated to be about 200 cubic kilometers. More than half of the memoir is given to local and petrographic details. A bibliography occupies 22 pages. The colored geo-

logical map might well serve as a guide to the observant traveler in this most picturesque district.

REVERSION IN RIVER DEVELOPMENT.

In the Seven-mountain district of Pennsylvania, the anticlines and synclines of the corrugated Medina sandstone, pitching gently eastward, form an extraordinary series of zigzag ridges. Streams rise in the apex of the synclinical reentrants and flow eastward with the pitch of each synclinical axis toward the Susquehanna; and these axial streams receive branches that descend the dip-slope of the linear monoclinal



ridges which diverge from each synclinal apex. Such a scheme of drainage has usually been called consequent; yet when it is remembered that the present relief has been developed by the removal of a great series of strong and weak strata it appears that the existing streams are not the persistent successors of the original consequents, but that they have reverted to ancestral conditions after having passed through a systematic series of metamorphoses, as indicated in the accompanying diagrams. The first section represents initial conditions. An original consequent stream (A') flows along the pitch of a synclinical axis of Pottsville conglomerate and is fed by lateral consequents ($L'A'$) from the slopes of the enclosing anticlines. Section 2 represents a later time when longitudinal subsequents have been developed along the anticlinal axes of the weak Mauch Chunk shales, thus shortening the laterals of the original system ($L'A'$) by favoring the growth of obsequents ($O'S'$). In section 3 the new subsequents have shifted down the dip of their determining formation, thereby developing a new lot of apparently consequent laterals ($L''S'$), and the initial trough has been reversed into a narrow synclinal ridge, crowned by a remnant of Pottsville conglomerate. The original axial consequent (A') has vanished and an anticlinal subsequent of the second order (S'') has appeared. With still further erosion, as permitted by successive uplifts, the two first-order longitudinal subsequents (S', sect. 3) coalesce by continued monoclinal shifting, and thus form a new axial stream (A'', sect. 4) with appropriate laterals ($L''A''$) in the trough of the Pocono syncline. By yet another series of analogous changes ending in the fifth section, a third-order axial stream will be developed (A''') fed by a series of third-order laterals ($L'''A'''$) on the Medina syncline, such as at present exist. Although these streams closely imitate the ancestral consequents of the first section (A',$L'A'$), it is evident that the imitation is due to reversion and not to the persistence of a fixed type. Streams of this kind might be called reversional consequents, renewed consequents, reconsequents, or simply resequents.

W. M. Davis.

CURRENT NOTES ON METEOROLOGY.

QUARTERLY JOURNAL OF THE ROYAL METEOROLOGICAL SOCIETY.

The January *Quarterly Journal of the Royal Meteorological Society* contains several articles of general interest. Dr. Nils Ekholm contributes a paper 'On the Variations of the Climate of the Geological and Historical Past and their

Causes,' which was presented at the recent Jubilee meeting of the Society. The subject is treated at considerable length under the following heads: (1) The general causes of changes of temperature. (2) Geological chronology. The probable age of the earth. (3) The radiation of the sun nearly constant during geological ages. The temperature of the earth's surface explained by the equilibrium between insolation and radiation from the earth into space. (4) Variations in the quantity of carbonic acid of the atmosphere the principal cause of the great climatic variations during geological ages. (5) The secular cooling of the earth is the principal cause of the variations of the quantity of carbonic acid in the atmosphere. Modifying influences. (6) Variations of the obliquity of the ecliptic and their influence on the climate. (7) Climatic variations during historical times, particularly in northwestern Europe. Conclusions. Probable variations of climate in the future. R. H. Curtis considers 'An Improved Mounting for the Lens and Bowl of the Campbell-Stokes Sunshine Recorder,' by means of which the glass ball can be quickly and accurately placed centrally in the bowl, where it is secured by clamping screws. W. H. Dines contributes a paper on the 'Weekly Death Rate and Temperature Curves, 1890–1899,' which contains diagrams showing the death rate of the thirty-three great towns of England, and also curves of the temperature at Greenwich. The author is of opinion that from the health point of view the English climate is one of the best in the world. A pleasanter climate may easily be found, but the majority of health resorts to which Englishmen go in the winter have a higher death rate than London has at the same season, and a far higher rate than any of the country districts of the British Isles. A paper by H. Mellish discusses 'The Seasonal Rainfall of the British Isles.' The rainfall returns from 210 stations are analyzed for the twenty-five years, 1866–1890, and the percentage of the mean annual rainfall for each season is determined.

THE OLD YUMA TRAIL.

A STRIKING account of the history of 'The Old Yuma Trail' is given by McGee in the *National Geographic Magazine* for March. The part played by the arid climate of the region is touched upon here and there, and the terrible loss of life along the Trail during the 'gold-fever renaissance' is thus described: "Many of the travelers were fresh from humid lands, knew naught of the deceptive mirage or the ever-hovering thirst-craze of the desert, and pressed out on the sand wastes without needful preparation. The roll will never be written in full, since most of the unfortunates left no records, scores leaving no sign save some bleaching bones; but observers estimate that there were 400 victims of thirst between Altar and Yuma within eight years, an estimate which so conservative a traveler as Capt. Gaillard thought fair, after he had 'counted sixty-five graves in a single day's ride of a little over 30 miles.'"

HANN'S LEHRBUCH DER METEOROLOGIE.

PUBLIC announcement is made of Dr. Hann's forthcoming 'Lehrbuch der Meteorologie,' a book upon which, as was known to his friends, the eminent meteorologist has been at work for some time. The volume is to be published by Tauchnitz, of Leipzig, and may now be subscribed for. It is to come out in eight successive instalments, costing 3 Marks each. Dr. Hann is so well known to scientific men the world over, through his admirable 'Handbuch der Klimatologie' and his many other shorter publications, that his new book, which is already assured a hearty welcome and a large sale, will be awaited with the greatest interest.

NOTES.

THE *National Geographic Magazine* for March contains a paper on 'The Sea Fogs of San Francisco,' which is an abstract of an article by A. G. McAdie in the *Monthly Weather Review* for last November. Five excellent half-tones accompany the paper.

THE *Bulletin of the American Geographical Society*, No. I., 1901, pp. 42–46, contains a paper by W. H. Alexander, Observer of the Weather Bureau, on 'St. Christopher, West Indies,' in which there are some statements concerning the climate.

THE full discussion of 'The Eclipse Cyclone and the Diurnal Cyclone,' by H. H. Clayton,

to which reference was made in these notes in SCIENCE for March 1, has appeared in Part I., Vol. XLIII., of the Annals of the Harvard College Observatory (pp. 33, pls. IV.).

R. DEC. WARD.

SCIENCE AND INDUSTRIAL COMPETITION.

Two small but very significant publications, recently issued from the press, will interest every intelligent citizen, and should particularly interest the man of science, the practitioner in applied science and, perhaps most of all, the always rare but always influential statesman.* The one is a reprint of letters to the London *Times*, the 'Thunderer,' from an able and distinguished British engineer traveling in the United States and reporting to that paper upon the aspects of 'American Engineering Competition'; the other is a series of addresses and magazine articles by Professor John Perry, the able and original electrician and engineer, upon methods of teaching the sciences. There is possibly an important connection between the two seemingly diverse subjects.

The one describes the latest and best, as well as the most important, of American methods and apparatus of industrial production. The universal adoption of scientific methods; the extensive employment of the product of inventive genius; the utilization of applied science in any and every possible way in the promotion of the arts; the adoption of scientific methods of organization, of administration and of maintenance of the great systems of industry, of production, transportation and distribution; the universal faith in and practice of systematic and scientific processes of ore-production and transportation, of trans-shipment, of reduction; the manufacture of iron and steel, 'manufacturing' all articles made of iron or steel rather than simply 'making' in older way; the part taken by automatic machines in the rapid transformation of the older into the newer system, with resulting increase of product per man, and of wages, and yet with decreasing costs and prices: all these elements of industrial progress are discussed. The other sharply arraigns the English educator for his utter neglect of the applied sciences and for his indifference to their utilization in the life and work of the English people, and attributes the later relative retrograde movement of Great Britain in part, at least, to this neglect of science and to the greater activity and the statesmanlike policies and methods of education of Germany and the United States.

The one traces in a most admirably complete, yet condensed and succinct, way the great movements in the fundamental industries of the United States during the past decades and up to its recent astounding development of a foreign trade. It closes a most intensely interesting and instructive and suggestive discussion by two chapters on the labor question, which this author seems to think a much more important element in the relative decadence of Great Britain as a manufacturing nation than even that neglect of science which has awakened Professor Perry's most serious apprehensions. In the other book, that distinguished electrician criticises, not the science-teacher so much, nor even the leaders in the industrial systems of his country, but the members of his own profession who, as he thinks, are themselves indifferent to the progress of science and to its utilization for the benefit of their country and profession. He criticises the methods usual in teaching mathematics, that ultimate basis of all engineering, and discusses in his characteristically original and forceful manner the defect of technical education in England and the defects of such as is attempted. Outside the work of the Science and Art Department at Kensington, he finds apparently little to approve. For that department he has cordial words of praise. His discussion may be taken as an important supplement to John Scott Russell's famous work.*

After reading these two little volumes one can hardly fail, however, to come to the conclusion that, while it is true that the American producer just now bursting into the field of

* 'American Engineering Competition,' being a series of articles resulting from the investigations made by the *Times*, London; N. Y. and Lond. Harper & Brothers, MDCCCCI. 8vo., p. 139. $1.00. 'England's Neglect of Science,' by Professor John Perry, M. E., etc., London. T. Fisher Unwin, 1900. 8vo., p. 113. $1.00.

* 'Systematic Technical Education,' London, 1869.

foreign consumption with his cheap but well-made 'interchangeable' wares, owes his seemingly meteoric success to applied science and in large part, in these later years, to the introduction into his manufacturing and transportation organizations of scientifically trained men, and while it is unquestionably the fact that Great Britain is suffering from neglect of science, and from the barbarous spirit and ignorance of her trades-unions, the real, the fundamental, element of difference probably lies behind all this. The ultimate cause of these developments of the United States which have so astonished the world is that perfect freedom, political and conventional, that freedom of the individual to mark out his own life and strive for his own highest goals, unhampered by governmental dictation or by bonds of caste, which has given the American citizen hope, ambition, purpose and effective energy. It is this which gave him invention, power of achievement, his patent laws, his legislation in behalf of essential industries, even his alert mind and his patriotism and love of country. It is this which has given us our common schools, which has promoted the organization of schools of the arts and trades and productive professions and the whole system of technical education and of industrially applied science. This has given our capitalist a new use for accumulated wealth in the endowment of schools of science and the promotion of education generally, has induced the adoption of organized industrial systems on such an enormous scale and has permitted the introduction of labor-assisting machinery without serious opposition on the part of those certain to be ultimately most benefited by the resultant increase of wages and decreased costs of product. Great Britain is still under the enslaving influences, in large degree, of convention and caste, and it is mainly this which lies at the bottom of her slow progress in the adoption of modern scientific methods, of improved systems and of extensive and intensive technical education.

Meantime, these two books will serve for the present as admirable summaries of progress to date and, later, will have great value historically.

R. H. THURSTON.

*THE MALARIA EXPEDITION TO NIGERIA.**

THE detailed report of the expedition sent out to West Africa last year by the committee of the Liverpool School of Tropical Medicine has not yet been completed, but its main conclusions can now be given. The expedition was under the direction of Dr. H. E. Annett, demonstrator at the Liverpool School of Medicine. Its main objects were: (1) the exploration and investigation of the conditions under which malarial fever occurs and is conveyed to Europeans, (2) the possibility of adopting any preventive measures against the disease, and (3) the corroboration and extension of recent discoveries and researches on the subject. In Nigeria there are no large communities of Europeans such as at Lagos, Accra, Cape Coast and Sierra Leone, but there were from three to ten white men at each of the stations, with the exception of Old Calabar and Lokoja, where they number a hundred or more. The observations of the members of the expedition confirm the recent discoveries regarding the cause of malarial fever and more especially the part played by mosquitoes of the genus *Anopheles* as the carrier of the disease from an infected to a non-infected person. The examination of the blood of the natives themselves corroborated the work of Professor Koch in the East Indies, and of the members of the Royal Society's Commission on Malaria in West Africa, that the blood parasite which gives rise to malarial fever in man is carried by the mosquito from the native to the European—and more especially from the native children. The examination of the blood of hundreds of native children revealed the interesting fact that between 50 and 80 per cent. of those under five years, between 20 and 30 per cent. of ages between five and ten years, and a small percentage over ten years contained malarial parasites, often in very large numbers. The breeding places of the *Anopheles* were found to be chiefly the dug-out native canoes in the regions of the mangrove swamps, claypits and puddles in the forested district, and at Lokoja puddles and ditches on and alongside the roads and footpaths. It was particularly noticed everywhere how carelessness in the construction of roads and footpaths, and more es-

* From the London *Times*.

pecially in the laying out of the areas surrounding the factories of the European traders was accountable for the production of a large number of breeding places for mosquitoes, which could easily have been avoided. In fact, it is certain that in West Africa such conditions are far more dangerous and more common than the proximity of a marsh or swamp, which is often noted as a cause of fever. Indeed, the mangrove swamp of West Africa has no direct relation to malarial fever, its presence only tending to predispose to a condition of general health rendering the subject more likely to the attack of disease in general. The observations of the members of the expedition lead them to very definite conclusions as to the methods to be adopted for the prevention of malarial fever among Europeans in West Africa. They consider that many of the methods which have been suggested are absolutely impracticable in West Africa—such as the universal dosing of infected persons with quinine for a period, the use of mosquito-proof houses, and of mosquito curtains, and the planting of trees of various kinds; although they are of opinion that such measures among an intelligent and obedient community may be of some efficiency. The two methods upon which alone any reliance can be placed as measures for prevention are (1) segregation of Europeans from natives of all sorts, at a distance of about half a mile; and (2) complete and efficient surface drainage of the whole district in the immediate neighborhood of European quarters. The adoption of these methods in many of the places visited by the expedition would be, even now, easy; in others, especially in the larger towns, it would involve considerable difficulty; but in the stations likely to be made in Nigeria in the near future their adoption would lead to the formation of malaria-free habitations.

---

*CONCILIUM BIBLIOGRAPHICUM.**

THE beginning of the twentieth century marks a new period in the history of the Concilium Bibliographicum. It is now just ten years since the origin of the movement which led in 1895 to the official foundation of the institution by the vote of the Third International Congress of Zoology.

Means were provided for carrying on the work for a preliminary period of five years, in order to determine whether the project could be made a success. The experimental stage is now passed and the verdict of all those who know the work well is that the high hopes entertained for the undertaking have been completely justified.

A recent report of the Swiss Society of Naturalists endeavors to estimate in a specific case the saving of time afforded by the card catalogue in obtaining references to recent publications in regard to the trout. The saving is estimated at half a day. But in regard to other cases the saving is far greater. Let any zoologist familiar with past bibliographical resources consider how he would go to work to ascertain what has been published in the past five years in regard to some minute question, such as the fauna of Sumatra. A moment's reflection will suffice to show that it would be a task of many weeks to obtain an answer to such a question. Yet a subscriber to the faunistic part of the bibliography of the *Concilium* would only require a few seconds to find 62 publications dealing with the question. The titles of ten of these publications would, it is true, bear no mention of Sumatra; they are classed here because on perusing the text important references to Sumatra were found. Some, indeed, bear titles that would seem absolutely to preclude any notes on the fauna of Sumatra, as, for example, a work on 'The Insects of Germany.' Subscribers to any considerable portion of the bibliography would have received these references for 80 centimes (8d. or 16 cents), and any per-

* From the general statement for 1900.

* An error was made in this item in our last annual statement, which we now correct.

son, whether a subscriber or not, could receive the information for 3 fr. 10 (2s. 6d. or 62 cents). Surely no comment is necessary to prove the value of the work nor the extreme cheapness of the service.

The gradual success of the work from a scientific standpoint has led to a corresponding improvement of the financial status of the work. For the first three experimental years there was an average annual deficit uncovered by the subsidies of Frs. 5625, while for the last year this deficit had fallen to Frs. 224.

All this has now induced the Swiss Government to take a step which decided the entire future of the enterprise. By a recent vote of parliament its subsidy isi ncreased fivefold, and arrangements are being made to give the work permanence by making it independent of the person of the present director.

In the past year great progress has been made towards bringing the bibliography up to date. For certain departments it is already the most complete bibliography in existence. At present the malacological department, which had been far behind, is being brought up to the standard of excellence maintained by the whole. Later, attention will be given to protozoa and worms, especially as regards notes contained in medical journals, and finally ornithology will follow.

The anatomical bibliography has recently received renewed attention. Indeed the number of titles is more than double that issued in the previous year and yet they form but a small part of the extensive manuscript now ready for publication. The publication of the physiological bibliography, on the other hand, has been suspended and can not be resumed for two or three months, in consequence of technical difficulties which can only be overcome by the purchase of new machinery. This unfortunately can not yet be obtained from the factory. In the meantime a complete set of guide-cards has been published.

The Concilium owns a manuscript card catalogue of new genera and species (including new names) which are recorded as soon as published. From 1901 on, copies of any part of this catalogue may be obtained at the uniform charge of 10 centimes per entry (minimum 50 centimes). Since the cards are arranged faunistically as well as systematically, most diversified orders can now be received, *e. g.:* New genera and species of trichoptera, of bombycids, etc., new genera and species described from the Cape Colony, from the Philippines, from Texas, from Perthshire, etc., new reptiles from Japan, or simply new species of Carabus or any other genus.

The usefulness of a card catalogue depends largely on its being properly mounted and supplied with guide-cards. The sets of guide-cards issued in previous years are described in a special circular. A description of the new card cabinets of the Concilium is also the object of a special pamphlet. American subscribers would find it, however, more profitable to turn to the well-known Library Bureau.

The cards thus far published have been taken from no less than 1,576 periodicals. A list of journals showing precisely what volumes and numbers have been excerpted is in preparation and will, it is hoped, soon be issued. Experiments are being tried with a view to opening new facilities of subscription in regard to the great faunistic areas. But above all, our program for 1901 is to render the references more complete and to approach more nearly our final aim, which is to *remove the entire burden of bibliographical research from the shoulders of the working biologist.*

In closing, we wish to thank especially the Swiss Government and the Elizabeth Thompson Science Fund for their generous support in the past, without which none of this work could have been carried on.

SCIENTIFIC NOTES AND NEWS.

Dr. H. A. Rowland, professor of physics in the Johns Hopkins University, died suddenly on April 16th.

Professor J. Willard Gibbs, of Yale University, has been elected an honorary member of the London Physical Society.

The University of St. Andrews conferred its LL.D. on Mr. Alexander Agassiz, of Harvard University, in April. Mr. Agassiz returned from his visit abroad last week.

The Board of Visitors to the U. S. Naval Observatory held its first meeting at Washing-

ton last week, with all the members in attendance. Professor Young, of Princeton University, was elected Chairman and Professor Stone, of the University of Virginia, Secretary. The members of the Board were received by President McKinley. They visited the observatory, and held a number of sessions, but the proceedings have not been made public.

AT the last meeting of the Rumford Committee of the American Academy of Arts and Sciences a grant of $300 was awarded to Professor Arthur A. Noyes in aid of a research on the effect of high temperatures upon the relative conductivity of aqueous salt solutions.

DR. W. KARAWAIEW has been appointed director of the zoological station at Sebastapol.

THE Washington Academy of Sciences has announced for Wednesday, April 17th, at 8:15 P. M., a lecture in honor of the National Academy of Sciences by Professor Alpheus Hyatt on 'A New Law of Evolution.'

THE spring lectures before the Royal Institute, London, include: Dr. Allen Macfadyen, six lectures on 'Cellular Physiology,' with special reference to the enzymes and ferments; Professor Dewar, three lectures on the 'Chemistry of Carbon'; Professor J. B. Farmer, two lectures on the 'Biological Characters of Epiphytic Plants,' and Mr. J. Y. Buchanan, three lectures on 'Climate, its Causes and Effects.' The Friday evening meetings will be resumed on April 19th, when a discourse will be delivered by Professor J. J. Thomson, on the 'Existence of Bodies Smaller than Atoms.'

AS we have already announced, Mr. J. H. H. Teall has succeeded Sir Archibald Geikie as director-general of the British Geological Survey. *Nature* now announces the following further changes in the staff: Mr. H. B. Woodward to be assistant director (for England and Wales), and Mr. John Horne to be assistant director (for Scotland); Mr. C. Fox Strangways, Mr. Clement Reid and Mr. Aubrey Strahan to be district geologists for England and Wales; Mr. B. N. Peach and Mr. W. Gunn to be district geologists for Scotland, and Mr. G. W. Lamplugh to be district geologist for Ireland.

PROFESSOR RUDOLPH VIRCHOW will be eighty years old on the 13th of October. When he celebrated his seventieth birthday, a fund was collected in his honor for the endowment of scientific research, and a committee has now been appointed to increase this fund as a further testimonial to Germany's greatest living man of science. It is intended that the testimonial shall be international, and a committee has been appointed in America consisting of Charles A. L. Reed, President of the American Medical Association; Henry P. Bowditch, President of the Congress of American Physicians and Surgeons; William H. Welch, Johns Hopkins University; Robert F. Weir, President of the New York Academy of Medicine; A. Jacobi, 110 West 34th Street. To Dr. Jacobi, who is secretary of the committee, subscriptions may be sent.

THE Geographical Society of Leipzig has made the first award of its Edward Vogel gold medal to Professor Schweinfurth, of Berlin. The Society has elected as honorary members: Professor Penck, of Vienna; Professor von den Steiner, of Berlin, and Dr. Alph-Stuebel, of Dresden.

KING EDWARD has consented to become patron of the Royal Institution, London.

PROFESSOR BRANNER, of the University of California, has sent us an extract from the *Southern Cross*, a newspaper published at Buenos Ayres, which gives a description of the unveiling of a monument in honor of the geologist, Burmeister, lately director of the National Museum in Calle, Peru. The monument is the work of the German sculptor, Aigner, and was erected by public subscription at a cost of $12,000. The statue, which is of marble on a large pedestal, represents Burmeister seated, holding a mineralogical specimen in his right hand. Commemorative addresses were made by the minister of public instruction and others.

WE record with much regret the death of Dr. William Jay Youmans, which occurred on April 10th, at Mt. Vernon, at the age of sixty-two years. Dr. Youmans, after a thorough education in science and medicine, joined his brother in the establishment of the *Popular Science Monthly* in 1872, and was editor-in-chief

of that journal after the death of his brother in 1887, until last year. In the editorship of the *Monthly* and in many other directions Dr. Youmans did much for the diffusion and advancement of science in America.

WE also regret to record the death of Professor John Thomas Duffield, for more than forty years professor of mathematics in Princeton University. He was born in Pennsylvania in 1823, and graduated from Princeton College in 1841, where he was first appointed tutor in Greek and in 1847 adjunct professor of mathematics. Dr. Duffield was the author of various publications on religious and mathematical subjects.

MR. ARTHUR COPPEN JONES died, at Davos, on March 8th, at the age of thirty-five years. Mr. Jones studied under Huxley at the Royal School of Mines, but was compelled to go to the Engadine when only 20 years old, owing to an attack of tuberculosis. When his health improved, he studied bacteriology and was the author of a paper advocating the view that the tubercle bacillus is a fungus. He translated Fischer's 'Structure and Function of Bacteria,' recently issued from the Clarendon Press.

DR. FRANZ MELDE, professor of physics in the University at Marburg, died on March 16th at the age of sixty-eight years.

MRS. EMMA FLOWER TAYLOR, daughter of the late Roswell P. Flower, has given $60,000 to Watertown, N. Y., for a public library in memory of her father.

THE committee, appointed by the International Congress of Geologists on the 25th, of August last, has announced as the subject proposed for the Spendiaroff prize for 1903 'A Critical Review of the Methods of Classification of Rocks' (Revue critique des mèthodes de classification des roches). The value of the prize is 456 roubles or about $240. Manuscripts should be addressed to M. Charles Barrois, secrétaire général du Congrés Gèologique International, 62, boulevard Saint Michel, Paris. At least two copies of papers submitted in competition are required, and they should be sent, at the latest, a year before the next session of the Congress in 1903.

PROFESSOR TODD writes from Port Said on March 25th, stating that the expedition sent from Amherst College under his direction to observe the eclipse of the sun in the Dutch East Indies, has reached that point two days ahead of his ephemeris and should be in Singapore on or before April 15th. The station for this observation of the eclipse is likely to be the little island of Sinkop, one of the lesser dependencies of the Sultan of Rhiow, about a day's journey southeast of Singapore. In addition to Professor Todd's apparatus for photographing the corona, which is partly automatic, Dr. Wright, of Yale, has provided an equipment of apparatus for determining the photographic polarization of the corona.

AN expedition to Samoa and the Pacific Islands for the study of mosquitoes in relation to the diseases which they bear has been planned at the instance of Dr. Patrick Manson. The sum of $5,000 has been subscribed anonymously and it is hoped that the British Government will assist. The *Lancet* states that here the investigators would set themselves to study the local mosquito, and, having obtained full knowledge of its habits, they would proceed to investigate the mosquitoes of an island in which malaria is endemic. They are then to convey the *anopheles* from the malarial to the non-malarial island and to endeavor there to breed the *anopheles* under laboratory conditions. In the aquarium thus formed there would be introduced certain plants and animals which are apparently peculiar to Samoa with the view to discover, in one or another of these, something antagonistic to the *anopheles*. The experiment would then be repeated under conditions as nearly natural as might be possible. Dr. Manson hopes that by this means there may be discovered a something which is hostile to the *anopheles*, and which may be subsequently turned to good account by being introduced into islands and localities where malaria is epidemic. The Pacific islands are suggested by Dr. Manson from the fact that they also afford unique opportunities for the study of filariasis and elephantiasis. In many of the islands this latter disease attacks from 20 to 50 per cent. of the population, and in others filariasis attacks from 30 to 60 per cent. But there are also small islands with populations of

from 200 to 300 in which elephantiasis is alleged not to exist, while there are other islands, equally small in population, where almost every individual is affected.

THE *Princeton Alumni Weekly* states that another geological expedition to the far West is projected for next summer, for the purpose of adding to the very valuable collections already in the university museums, a large part of which have been gathered by this means during the last twenty-five years. Ten or a dozen upper classmen are expected to compose the party, besides Dr. M. S. Farr, '92, the new curator of vertebrate paleontology, who will be in command, since Professor W. B. Scott, '77, who has led so many of these expeditions, expects to be in South America next summer. Southern Montana will be the principal field of exploration, though, after two months of research, the party will have a pleasure trip of two or three weeks in the Yellowstone National Park. Dr. Farr expects to go out to Montana about the middle of May to make the arrangements, the other members of the party following after commencement.

THE American Physical Society will hold its next meeting in New York City, on April 27th. The program committee is Professors J. S. Ames, M. I. Pupin and Ernest Merritt.

THE Secretary of the National Educational Association, Mr. Erwin Shepard, has sent out a notice stating that the arrangements for the fortieth annual convention at Detroit next July are progressing satisfactorily. The hotels have agreed not to advance their rates and accommodations for ten thousand teachers are being secured in private houses. The official program will be issued on May 1st.

THE eighteenth annual meeting of the American Climatological Association will be held at Niagara Falls on May 30th and 31st and June 1st. The program includes a special discussion on the home treatment of tuberculosis.

THE Congrès des Sociétés Savantes held last week its annual conference at Nancy. Various geological and archeological explorations have been arranged to follow the Congress.

THE inaugural meeting of a society for the study of psychology by experimental methods was held in London on April 16th.

THE Anatomical Society of Great Britain and Ireland will hold its summer meeting at Leeds on July 5th and 6th.

THE spring meeting of the Iron and Steel Institute of Great Britain will be held on Wednesday and Thursday, May 8th and 9th, at the Institution of Civil Engineers, London. The retiring president, Sir William Roberts-Austen, will introduce the president-elect, Mr. William Whitwell, who will deliver an inaugural address. The Bessemer Gold Medal for 1901 will be presented to Mr. J. E. Stead. The autumn meeting of the Institute will be held in Glasgow on September 3d and following days.

THE U. S. Fish Commission will make an elaborate exhibit at the Buffalo Exposition, and this is now being arranged by Mr. W. de C. Ravenel, assistant in charge of the division of Fish Culture. There are to be fifty tanks containing fresh and salt water fishes shown as nearly as possible in their natural surroundings. Hatcheries will be in operation throughout the entire summer. There will also be a full exhibit of methods of fishing and of the products of fisheries, including the secondary products, such as oil, shells, skins, etc.

WE learn from the British *Medical Journal* that the Institute of Tropical Medicine established by the Senate of Hamburg, with the support of the German Empire, will shortly be in working order. It is housed in the Old Seamen's Hospital, Hamburg. The director of the Institute is Dr. Nocht, formerly port medical officer of Hamburg. He did admirable service to Hamburg in the cholera epidemic of 1892. He was formerly a surgeon in the German army, and afterwards worked under Professor Koch in the Institute of Hygiene at Berlin. Dr. Nocht has made original researches on the parasitology of malaria. He will have as his assistant in his new office Dr. Ollwig, who accompanied Professor Koch in his tropical expedition.

A MUSEUM of ethnology has been established at the University at Breslau, through the efforts of Dr. Thilénius, professor of anthropology and ethnology.

IN connection with the Munich veterinary school, a station has been established for the study of the diseases of fishes.

PLANS for the lion house of the New York Zoological Park have been approved by the executive committee of the Zoological Society.

SIR JOHN MURRAY, who has just returned from a six months' expedition to Christmas Island, during which he crossed the island from end to end—the first occasion on which it has been traversed—has made a statement with reference to his travels to a representative of Reuter's Agency. Christmas Island, which is situated in the Indian Ocean, is 220 miles from the nearest land, and is some 12 miles long by seven broad. It is covered with dense forest, having an area of nearly 50 miles, and the sea depth around its shores is between three and four miles. There is no good anchorage, but only an open roadstead. When Sir John Murray was on the island there were 13 whites, including a doctor, chemist and engineer, living there with their families, together with 720 Indian coolies engaged in working the rich phosphate deposits. The animals and plants on the island are of extreme interest. The whole place is overrun with curious red crabs as much as 18 inches across. They are excellent tree climbers, and once a year there is a regular migration of these crustaceans, who travel in bodies like ants, taking 15 days on the journey, and returning inland after hatching their eggs. There are only five mammals on the island, including two species of rat not known elsewhere. They are of two colors, those on the plateau being brown, while those nearer the coast are black, and in order to keep them down a number of terriers have been imported. On the island are also to be found a toothless snake and a blind snake much like a worm. In exploring the island Sir John Murray had to cut a track through the dense forest until he reached the central plateau at an altitude of 1,000 feet, where traveling was not so difficult. One night he got lost in the forest, and had to subsist on the tops of sago palms, which he cut down. The island is under the Straits Settlements Government, and a resident magistrate has just been despatched thither from Singapore, together with an official of the Public Works Department, a scientific commission, and a force of police, 35 in all. They will select sites for the administrative buildings to be erected on the island. The climate is perfect, like a hot English summer, and prior to the British annexation no human being is supposed to have lived on the island.

THE annual general meeting of the Chemical Society was held at Burlington House, London, on March 28th. Professor T. E. Thorpe, the president, made an address in the course of which he said according to the London *Times*, that they were proud to think that the Society, in so far as it had administered to the progress of chemistry, might have contributed in some measure to the luster of the reign which had been eminently associated with the spread of science. They had never been unmindful of what their science owed to the royal family, and in particular to the late Prince Consort. They entered on the 20th century mustering 2,368 members, including 33 foreign members. Since the last anniversary 182 communications had been made to the Society, a number greater than that of any preceding year. The volumes published in 1900 by the Society contained 3,758 abstracts of papers, which had appeared mainly in continental journals. For some time past their sister society in Berlin had had under consideration the desirability of establishing, with the cooperation of the various chemical societies in Europe and America, a uniform system of atomic weights. The committee appointed by the Society had decided to recommend that $O=16$ be taken as the basis of calculation of atomic weights, and that in assigning a number as the atomic weight of any element only so many figures should be employed that the weight might be regarded as accurately known to one unit in that figure. Some discussion had taken place with regard to the time of the Society's meetings, and the council had decided provisionally to hold the meetings during the coming session at 5:30 P. M. on the first and third Wednesdays of the month. Professor Reynolds J. Emerson was elected president for the ensuing year.

A DESPATCH from New Orleans to the daily papers states that the investigation made by Professor Beyer for the American Ornithologi-

cal Association of the Louisiana Gulf Coast for the purpose of stationing wardens to protect the sea birds shows that action was not taken a moment too soon. Professor Beyer found that nearly all the breeding places of the birds had been destroyed by killing the birds themselves and taking their eggs. Not a trace of birds was found on either Brush or Caillou islands, at one time the home of millions of seafowl. The same was true of Calumet and Castelle islands, on which every living thing had been killed. A few gulls and hens were found left on Timbalier Island, and there are said to be a few on Last Island which, however, could not be visited on account of the severe weather. Wardens were appointed wherever birds were found and the fishermen of the neighborhood promised to cooperate with the wardens in preventing the killing of the birds in the breeding season and the stealing of eggs.

THE report of the British Consul at Naples for the past year, as summarized in the London *Times*, describes the recent progress of the Marine Zoological Station in that city, 'the mother of all similar scientific establishments in the world.' Its progress has continued with undiminished activity, and the number of biologists of all nationalities who have carried out their investigations there has largely increased. During the past two years 63 and 71 scientists respectively have availed themselves of the opportunities of research afforded by it. Among other students at the station there has been a regular succession of naval officers sent by the Italian, Russian, German and Spanish governments for the purpose of undergoing a course of training in the commoner methods employed in capturing, investigating and preserving marine organisms. The work done at the station is for the most part of purely scientific interest, but a great many of the contributions to science are of great and immediate practical value. A report of great scientific and economic value has been prepared by the Cavaliere Lo Bianco, the permanent naturalist attached to the station. It contains the results of many years' assiduous study of the seasons of the year at which the animals, as distinguished from the plants, which inhabit the Bay of Naples, breed.

THE Royal Irish Academy has this year taken a step, says *Nature*, which will, it is hoped, still further establish its position in Ireland, and in the world of sciences and letters in general. It has adopted the principle of the byelaws of the Royal Society of London, respecting the mode of election of members; the council is now empowered to select a number of persons, not exceeding twelve, in each year, from the list of candidates for membership proposed, and to recommend these to the body of members for election. The members may, at the single annual meeting at which elections now take place, substitute the name of any candidate already proposed for that of any candidate selected by the council; but the number of candidates elected must not be greater than that fixed by the council for that particular year. Changes have been also made in the byelaws so as to provide for the more frequent introduction of new blood into the council. The position of the Royal Irish Academy becomes at the same time defined in relation to the other great medium of scientific publication and intercourse in Dublin, the Royal Dublin Society. While the latter, by its objects and foundation, must be to a large extent a popular institution, performing its important public functions and scientific work by the support of an extensive body of members, the Royal Irish Academy is able, on the other hand, to maintain its membership as a distinction, and to attract to itself, by this circumstance, those who are mainly concerned with the furtherance of research.

PARTICULARS in regard to the research scholarship founded by Mr. Andrew Carnegie in connection with the Iron and steel Institute of Great Britain, of which association Mr. Carnegie is a vice-president are given in the London *Times*. For this scholarship Mr. Carnegie presented to the institute twenty two $1,000 Pittsburg, Bessemer and Lake Erie Railroad Company 5-per-cent. debenture bonds, the income derived from which will be applied to awarding annually one or more scholarships of such value as may appear expedient to the council of the institute. The awards will be made on the recommendation of the council irrespectively of sex or nationality. Candidates, however, must be under 35 years

of age, and application must be made on a special form to the secretary of the institute before the end of April in every year. The scholarships will be tenable for one year, but the council will be at liberty to renew them for a further period if thought desirable instead of proceeding to new elections. The object of this scheme of scholarships is not to facilitate ordinary collegiate studies, but to enable students who have passed through a college curriculum, or have been trained in industrial establishments, to conduct researches in the metallurgy of iron and steel and allied subjects, with the view of aiding its advance or its application to industry. It is suggested that the National Physical Laboratory—on the governing body of which the Iron and Steel Institute is represented—would for many reasons be a very suitable establishment in which such a research could be carried out. There is, however, no restriction as to the place of research that may be selected, whether university, technical school, or works, the only absolute condition being that it shall be properly equipped for the prosecution of metallurgical investigations. The results of the researchs are to be communicated to the Iron and Steel Institute in the form of a paper to be submitted to the annual general meeting of members. If the paper appears to the council to be sufficiently meritorious the author will be awarded the Andrew Carnegie gold medal. The awarding of the medal in any year, however, will not be obligatory, but will depend upon a paper of sufficient merit being communicated.

In reply to those who have signed a petition objecting to the opening of the Edinburgh Museum of Science and Art on Sunday afternoons, Lord Balfour has written: "In point of principle I am unable to agree that a visit to a museum is a contravention of any divine law. If a citizen of Edinburgh may not go to a museum, by what right does any one of us enjoy a walk in our own or somebody else's garden? In deciding the practical question, I think we must keep in view the extent of the innocent gratification as well as improvement offered to those whose opportunities for both are otherwise limited. I believe that in these respects the advantages will be very great as compared with the amount of labor involved. Having regard to this, and bearing in mind the resolution of the House of Commons, I had but little difficulty in coming to the conclusion that it was my duty to decide the question of Sunday opening in the case of the Edinburgh Museum in the way I have done. I did not arrive at that conclusion without careful and anxious consideration, and I cannot hold out any hope that it will be reconsidered unless and until experience of its working in Edinburgh supplies proof that slight use is made of the opportunity offered or that its consequences are in some way detrimental to the public interests."

UNIVERSITY AND EDUCATIONAL NEWS.

By the will of the late Mrs. Josephine L. Newcomb, Tulane University will receive a large sum, said to be $2,000,000, for the Sophie Newcomb College for Women.

Mrs. P. D. Armour and her son Mr. J. Ogden Armour have given $1,000,000 to the Armour Institute, Chicago. This endowment will be used, it is said, to extend the work of the Institute in the direction of electrical engineering and chemistry.

The daily papers report that the endowment fund of $1,000,000 for the Johns Hopkins University has been practically collected and that the donors will be announced on May 1st. It is also said that President Gilman's successor will be announced at that time.

Mr. John B. Gilfellan, of Minneapolis, has given the University $50,000 for the assistance of poor students.

Creighton University at Omaha, Nebr., has received $75,000 from Mr. John A. Creighton for a new building.

The Board of Regents of the University of Minnesota has approved the recommendation of the faculties abolishing the degrees of bachelor of philosophy and bachelor of science, the degree of bachelor of arts being hereafter given for all liberal studies.

Miss Laura D. Gill will be installed as Dean of Barnard College on May 1st. A gift of $5,000 to the College from Mr. Jefferson Seligman has been announced.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, APRIL 26, 1901.

CONTENTS:

Convocation Week 641
The National Academy of Sciences 643
The Social Service of Science: PROFESSOR WILLIAM HARMON NORTON 644
The Gravity Measures of Europe and of the United States: DR. JOHN F. HAYFORD 654
The American Institute of Electrical Engineers: W. C. ANDREWS 655

University and Educational News 680

CONVOCATION WEEK.

THE action of the Association of American Universities recommending the adoption of a 'convocation week' to permit learned societies to hold their meetings at some other period than during the summer vacation has already been reported in these columns. The action was taken in consequence of the request made officially to the Association by the committee appointed by the American Association for the Advancement of Science. The vote determining the recommendation was unanimous, and has now been reported formally to the fourteen universities which are members of the Association making the recommendation. The next step must be the adoption of the plan by our higher educational institutions. It is therefore desirable that all scientific men should understand the project, which may properly claim universal support.

The week proposed is that in which January 1st falls. In some universities, as for example Yale, this week is already included in the regular vacation, so that for them no change is involved. Many universities have already a vacation beginning just before Christmas and extend-

ing to the second or third of the following January. For them the changes will be slight. In those cases in which the two or three days involved cannot, in the opinion of those deciding, be spared, it will probably be practicable to shorten correspondingly one or more of the vacations at other periods of the year. As regards the few colleges and technical schools which do not have the usual Christmas vacation, it may be suggested that it will suffice to vote to grant leave of absence during convocation week to those who desire to attend the society meetings, and perhaps later, when the 'week' has an assured and clearly permanent place these institutions, will conform to what will then be a recognized as a prevailing custom.

Columbia University has the honorable distinction of being the first to adopt the important innovation, and has already changed its calendar for 1901–1902, setting free the week of January first for convocation purposes. It is expected that several other universities also will soon announce their adherence to the plan, and it is hoped that in a short time the majority of American and Canadian universities will adopt the recommendation under consideration.

The reasons for asking for the establishment of a convocation week are obvious, since they are the direct outcome of conditions and experiences which are distinctively American and are familiar to all.

The general proposition that annual meetings of scientific men are desirable requires no demonstration. Every one realizes that, after remaining a long time within the circle of his own university, it is immensely stimulating to meet with a number of other men, pursuing the same branch of science. Moreover, the oral presentation of the results of investigation has certain real advantages over the written form, while the informal discussions at meetings are frequently worth more than the whole cost and trouble of attendance. The gain in these ways and many others is so great for the professors that it must be considered an important part of sound university policy to encourage and promote attendance at scientific meetings, since thereby a university can easily, and often greatly, increase the value of its teaching staff.

It is to be recalled next that attempts to hold meetings in summer time encounter difficulties so serious that such attempts are and can be only partially successful. It is the conviction that this difficulty is great and without remedy which has led the American Association for the Advancement of Science to wish to change its time of meeting to the winter season. It accordingly appointed a committee to take necessary action for this purpose. The committee, of which Dr. Minot is chairman and Professor Cattell secretary, is constituted by Charles S. Minot, President-Elect; R. S. Woodward, President; L. O. Howard, Permanent Secretary; E. L. Nichols and J. McK. Cattell.

The tropical character of the American summer has led to the gradual extension of the national custom of scattering to mountain, seashore and country, and those connected with universities utilize the long vacation to settle down in a summer home, from which it is more than difficult to en-

tice them. It must be further remembered that all those whose studies are with nature—the geologists, botanists, zoologists, anthropologists and others—use the summer for their expeditions, so that for many of them attendance at summer meetings is impossible.

On the other hand, there has grown up within the last dozen or fifteen years the custom of holding meetings of learned societies during the brief Christmas holidays. The first society to adopt this time for its gathering was the American Society of Naturalists, which held its first December meeting in New York, in 1883. Since then a number of other societies, more or less national in scope, have been formed and hold their meetings during the same period. We may mention among scientific societies the following:

The American Society of Naturalists.
The American Morphological Society.
The Association of American Anatomists.
The American Bacteriological Society.
The American Physiological Society.
The American Psychological Association.
The American Folklore Society.
The American Society of Plant Morphology and Physiology.
The Anthropological Section of the American Association.
The Geological Society of America.
The American Chemical Society.
The American Mathematical Society.
The American Physical Society.

All these societies, we think, without exception, have found from experience that the Christmas holidays are a convenient time for their meetings, except in one respect—that the time is too short, especially when Christmas day falls on a Wednesday or Thursday, for then Sunday falling half way between Christmas and New Year, it is impracticable to get more than two days for a meeting, and two days, as we have all learned, is far too brief a time for our needs.

These circumstances point obviously to the lengthening of the Christmas vacation past New Year as the remedy, hence the selection of the week in which the first of January falls as 'convocation week.'

Should the proposition be carried out, it will afford an opportunity for the elevation of science in America of inestimable value and will be a contribution to the advancement of learning in all its branches, well worthy to initiate the progress of the new century.

THE NATIONAL ACADEMY OF SCIENCES.

THE annual stated session of the National Academy of Sciences was held in Washington, April 16 to 18 inclusive. The following papers were read:

'The Climatology of the Isthmus of Panama': HENRY L. ABBOT.

'The Effects of Secular Cooling and Meteoric Dust on the Length of the Terrestial Day': R. S. WOODWARD.

'The Use of Formulæ in demonstrating the Relations of the Life History of an Individual to the Evolution of its Group': ALPHEUS HYATT.

'Artificial Parthenogenesis and its Relation to Normal Fertilization': E. B. WILSON.

'Simultaneous Volumetric and Electric Graduation of the Condensation Tube': CARL BARUS.

'Table of Results of an Experimental Enquiry regarding the Nutritive Action of Alcohol, prepared by Professor W. O. Atwater, of Middletown, Conn.': Presented by J. S. BILLINGS.

'The Significance of the Dissimilar Limbs of the Ornithopodous Dinosaurs': THEO. GILL.

'The Place of Mind in Nature': J. W. POWELL.

'The Foundation of Mind': J. W. POWELL.

'Conditions Affecting the Fertility of Sheep and the Sex of their Offspring': ALEXANDER GRAHAM BELL.

'The New Spectrum': S. P. LANGLEY.

Mr. Alexander Agassiz, of Cambridge, Mass., was elected president of the Acad-

emy; Professer Ira Remsen, Baltimore, Md., foreign secretary; Mr. Arnold Hague, Washington, D. C., home secretary—each for a term of six years. The following were elected additional members of the council for the ensuing year: J. S. Billings, G. J. Brush, H. P. Bowditch, Arnold Hague, Simon Newcomb, L. P. Langley.

Five new members were elected as follows:

George F. Becker, U. S. Geological Survey, Washington, D. C.

J. McKeen Cattell, Professor of Psychology, Columbia University, New York City.

Eliakim H. Moore, Professor of Mathematics, University of Chicago, Chicago, Ill.

Edward L. Nichols, Professor of Physics, Cornell University, Ithaca, N. Y.

T. Mitchell Prudden, Professor of Pathology, College of Physicians and Surgeons, Columbia University.

The following were elected foreign associates:

J. Janssen, Director of the Observatoire d'Astronomie Physique, Meudon, France.

Mr. Loewy, Director of the Observatoire de Paris, Paris.

E. Bornet, of the Section of Botany of the Paris Academy of Sciences.

Hugo Kronecker, Professor of Physiology in the University of Bern.

A. Cornu, Professor of Physics, École polytechnique, Paris.

F. Kohlrausch, Professor of Physics at the University of Berlin.

Sir Archibald Geikie, recently Director of the Geological Survey of Great Britain.

J. H. van't Hoff, Professor of Chemistry in the University of Berlin.

The Henry Draper medal was awarded to Sir William Huggins, of London, for his investigations in astronomical physics.

---

*THE SOCIAL SERVICE OF SCIENCE.**

The extent to which society may be considered as an organism is still, I understand, a matter of controversy with sociologists, but without awaiting its adjudication, we may surely make use of a simile as ancient as that of the Apostle who spoke of individual Christians as members of one body, or as that of the wise old Roman who taught the mutinous plebs the parable of the body politic, all of whose members were nourished by the well-fed patrician belly, and consider together this evening the special function of science in the body social.

It may at least supply a convenient means of classifying the various services of science to the common weal, if we consider it not as a distinct corporal member, but rather as a growth force, ever accelerating the evolution of society, providing it with organs of defense, increasing its muscular energy, and perfecting its systems of circulation and communication. And if to these services we add the reaction upon the social mind of the physical environment which science has provided, and the direct influence of scientific truth, we shall then have sketched at least the main functions of science in social evolution.

Among the first services to society which our biologic analogues suggest is that of defense. Under the growth force of science the body social has accomplished an evolution similar to that which brought the vertebrates, assumed to have been at first naked and defenseless, to the stage of the armored fishes of the Devonian, and which in the Tertiary changed tooth to tusk, nail to claw, and frontal boss to horn and antler.

Prescientific society was destroyed largely because it had attained no adequate means of defense. It is safe to say that had the Roman legionaries been equipped with Maxims and Mausers, the episode of the Hun and Vandal invasions of Southern Europe would have been indefinitely postponed.

Modern society, which science has armed with the most terrible of death-dealing weapons, whose explosives are brought from the laboratory of the chemist, whose im-

*Address of the retiring President, Iowa Academy of Science. Des Moines, December 26, 1900.

mense guns are fired at ranges which require the rotation of the earth to be taken into account, and with a precision which considers the difference in density of the air at the top and at the bottom of the bore, whose war ships are armored with the latest discoveries of metallurgy, their turrets turned and their guns loaded and trained by the electric current, and their evolutions directed by invisible vibrations of ether—surely a society thus armed has nothing to fear from any barbarian peril, be it yellow or be it black.

Civilization is safeguarded by science not only from the irruption of savage hordes, but also from the invasion of disease, from such epidemics as that which in the middle of the 14th century swept away more than half the population of England, and twenty-five millions of people in Europe. To-day when the plague appears in San Francisco or in London, it excites little more alarm than Gibraltar would feel at the assault of the Moor. By the simple remedy of vaccination science has saved in each generation of the century more lives, it is said, than were lost in all the wars of Napoleon. Among civilized nations within the last five centuries the death rate has been so lowered that the average duration of human life has nearly doubled. Medicine no longer attacks disease with charm, exorcism and nostrum; she obtains her weapons from the armory of science. From chemistry she brings a pure materia medica, new compounds, new processes, new methods of diagnosis, and anesthetics which have made surgery painless. From physics she obtains the appliances of electro-therapeutics, a delicate cautery, and the Röntgen ray, used by physicians in almost every town of size in Iowa within less than half a decade of its discovery.

The debt of the healing art to the sciences of the biologic group is so vast that I will select but one, bacteriology, for illustration. It is to no lucky chance that the discovery is due of man's most subtle and deadly foes, the bacteria. The work of Pasteur, the pioneer, and of his illustrious followers, is marked by the most thorough and painstaking investigation, and the most searching and rigid tests. It is by the application of the scientific method that the enemy has been unmasked, his ambuscades and chosen places for assault discovered and rational methods for his destruction demonstrated. It is men of science who have organized the victory of medicine today over diphtheria, rabies and the plague, over the venom of the snake and all the diseases to which serum therapathy is successfully applied. And where the bacteriologist cannot as yet supply a specific for disease, he can often point the way to its prevention. When the access to the human system of the germs of typhoid and cholera by drinking water is demonstrated, Hamburg builds its filter beds at a cost of $2,280,000 and Chicago expends $33,000,000 upon the drainage canal. And so with the great white plague, tubercular consumption. Science has proved the lurking places of the contagium in the sputum, and its carriage in the air we breathe, and reinforced by the high moral sense of our people, she is fast making it as impossible for the consumptive to spit on the pavement unhindered as for the smallpox patient to walk unarrested down our streets.

And who can estimate the number of lives now saved in each generation by aseptic surgery? So long as putrefaction was held, as by Liebig, to be due to the action of the oxygen of the air, no remedy for it could be suggested; but when once its bacterial origin was proved, the step was inevitable to those precautions which have rendered safe and successful the marvelous operations of modern surgery.

Micro-biology extends her ægis also over

the herds and crops of man. She destroys the insect enemies of our grain fields and protects vine and fruit tree from blight and mildew. She saves the silk-worms of Europe from the plague threatening their destruction, and the flocks and herds of America from some of their most destructive diseases.

Thus science performs a service to society incalculable in its value. It defends it from foes both within and without the gates. It prolongs life, assuages pain, lessens disease and makes death a euthanasy. So notable have been its victories during the century that we may almost prophesy the coming of the time when the only deadly bacillus remaining will be that as yet undescribed species, *bacillus senectutis*, or at least when only sufficient disease will be left on earth to provide for a speedy and beneficent extirpation of the unfit.

Viewing organic evolution from the angle of the physicist and considering the animal body simply as a machine for the transformation of potential into kinetic energy, the secular process sums itself up in the production of better and better machines. From the fish of the early Paleozoic, on to the amphibians of the Carboniferous, the reptiles of the Mesozoic, and the mammals of the Tertiary and of the present, we have a series of higher and higher organisms, each capable of doing more work and better work than its predecessors.

It is possible to construe social evolution in the same terms. Primitive society was weak. The energy at its disposal was that only of the human body, the beast of burden, and, to a limited extent, of wind, water and flame. So feeble was the ancient state in what may be termed its musculature, so little could it utilize the forces of nature, that it may be compared with a stage of organic evolution preceding that of the vertebrata, that, let us say, of the turbellarian worm, 'whose arrangement of muscles,' biologists tell us, 'is far from economical or effective.'*

In comparison modern society may be likened to one of the higher mammalia, such as the tiger or the elephant, which can not only take up from nature the maximum of energy, but can also apply it in varied movements and a highly complicated conduct.

Consider the vast stores of energy which society has to-day at its disposal. The steam power of the United States alone equals the day labor of one hundred million men. Behind each man, woman and child of the nation stands more than one automaton of steel, with the strength of a man but with manifold his capacity for productive labor. In carding, for example, fingers of steel do in half an hour what the unaided workman of a century ago could not have accomplished in less than eight months. Society finds in machinery a tireless hand capable of performing the mightiest and the most delicate of tasks with equal ease. It strikes with the steam hammer a blow of 2,000 tons, and it rules the Rowland grating with its 48,000 parallel lines to the inch.

Consider also the new induement of energy which science has bestowed upon society in the gift of electricity, a power capable of the swiftest and most ready transmission, of infinite subdivision, and of the greatest known intensity of concentration. And how varied is its functioning. In mine and quarry it picks and drills and fires the blast. At the wharf it lifts and loads and carries. In the factory it forges, casts, welds and rivets. In the home it shines in the most healthful light yet made by man. In electrolysis it produces a hundred substances of value, such as the caustic alkalies, bleaching powder, chloroform, the chlorates, and aluminium, the metal perhaps to give name to the new

* J. M. Taylor, 'Whence and Whither of Man,' Morse Lectures, 1895, N. Y., 1896, p. 47.

century. From the refuse of the mine it extracts millions of dollars worth of the precious metals. It surfaces the common metals with those more beautiful and precious, and copies infallibly the engraved plate of the map and the type-set page. In the electric furnace it creates new compounds, calcium carbide the source of acetylene gas, carborundum the abrasive of the future, and calcium nitrate, which promises a new source of nitrogen to fertilize and renew exhausted soils everywhere. It aids in the synthesis by which the chemist builds out of the inorganic the dye, the perfume, the essence, and soon perhaps the food, which nature builds only by the processes of life. Such are some of the functions of the new muscular system with which electrical science has equipped the body social.

It is not claimed that pure science is the only factor in industrial progress. Invention, business sagacity, and many other causes cooperate. But the work of science is essential, fundamental, creative. How far unaided invention can go may be seen in China. Here is a people once pliant of intellect and inventive. As artificers they still are given high praise. But Chinese invention, destitute of all scientific foundation, stopped with the fire cracker, the movable type and the directive loadstone. It could not possibly go on to the Lyddite shell, the Hoe printing press, and the compass of Lord Kelvin. Invention is applied science, and as has been well said, science must first exist before it can be applied. Between the scientific investigator, the discoverer of principles, and the inventor who applies them, there need be no jealousy. If the last has the popular fame and the financial reward of the present, it is often to the first that the future belongs, and, in any event, in the words of the generous Schley at Santiago 'There is glory enough for all.' And after all why should the name of science be refused to that vast body of knowledge, classified and tested, which is in daily use in the laboratories of the industries of the world.

But to science even in its most restricted sense the debt of society is incalculable. It has evoked those good genii, steam and electricity. Watt was led to the invention of the steam engine, not by a boy's glance at his mother's tea kettle, but through the discovery by Black of latent heat and after two years of profound study of such abstruse problems as the specific volume of steam and its law of tension under varying temperatures. And the improvements in the steam engine, which since the fifties have more than doubled the speed of the piston, while saving at least one-fourth of the fuel, have been made under the guidance of Joule and the mechanical theory of heat. In the matter of the advantage of superheated steam and high pressure, theory still seems to outrun practice.

In electricity the mechanic can take no important step beyond the scientific discoverer. How happy was the thought which designates the various units of electricity by the illustrious names of the masters of research: volt, in honor of the professor in the University of Pavia, who, one hundred years ago, gave the world in his crown of cups its first effective reservoir of the new power; ampère, the name of the professor of physics in the College of France, founder of the science of electro-dynamics; ohm, in memory of the professor of experimental physics in the University of Munich, discoverer of the law of the strength of the electric current; and farad, in honor of the greatest of them all, Michael Faraday, professor of chemistry in the Institution of England, the prince of experimenters, whose researches, resulting in the dynamo, connected the industries of the world with the first economical source of electrical energy.

Illustrations of the dependence of industry on pure science are everywhere at hand. When, as an amateur in photography, I take up a package of eikonogen or hydroquinon, the label with the name of one of the great aniline factories of Germany, at Elberfield, Mannheim or Berlin, reminds me of the debt of the *Farbenfabriken* to men of research. To the chemist is not only due the discovery of my developers, and of such other by-products as antipyrine, cocaine, saccharine and vanilline; it was he who first found in the black amorphous coal tar, the former refuse of the gas works, those brilliant crystalline dyes which have so largely replaced other colors in the dye vats of the world. So far as I am aware, no monument has been raised to these discoverers, to Hoffman, Graebe and Liebermann. In a more telling way industry acknowledges her debt to pure science when a great aniline factory such as that at Elberfield employs sixty professional chemists, and turns the attention of twenty-six of them to pure research in discovery of new compounds.

Science has thus given society command of energies of the highest efficiency. It has made the comforts of life common and cheap, it has lifted from the shoulders of labor its heaviest burdens and set free for higher social services all who are capable of their performance. It is the undiminishing fountain whence flows the world's material wealth.

The evolution of the circulatory system in the body physiologic suggests a similar development in the body social. The process which during the geologic ages slowly changed the primitive gastro-vascular cavity to the perfected circulation of the higher animals to-day, which evolved from a simple pulsating tube the powerful four-chambered heart, may at least serve as a simile to the evolution of the distributory or transportative system of modern society. So obvious is the analogy that the arteries of commerce is a phrase of common parlance. But for our purpose it will not be necessary to carry the likeness into details, to discriminate, as some ingenious sociologists have done, the various organs, such as the capillaries of the body social, or to liken the red corpuscles of the blood to the golden discs of the circulating medium. Let it suffice to show that by the application of the discoveries of science society has obtained a system incomparably rapid and effective for the distribution of power, of food and of all the products of labor.

The world is enmeshed by lines of railway and steamship. They carry the products of our Iowa farms to western Europe, to South Africa and to China. To our dinner tables they bring in return linen from Ireland, porcelain from France, cutlery from old England and silverware from New England, meats and fruits from States as distant as Texas, California and Florida, spices from the East Indies, and beverages from Japan and Java and the valley of the Amazon. In the United States alone there are now in operation nearly 200,000 miles of railway carrying each year a billion tons of freight and five hundred and fifty millions of passengers.

The carriage of power is accomplished at present almost wholly by the transportation of fuel. The value of this service may be seen by contrast with some railroadless country such as China, where, according to Colquhon, coal selling at the mine at fifteen cents per ton costs as many dollars ten miles away. But the future doubtless has in store the distribution of power as an article of merchandise. The possibility of long-distance transmission of electricity has already been demonstrated at Niagara, and the time may be near when in our cities power from coalfield or waterfall may be purchased for use in factory and home as readily as water or gas to-day.

What has been said already of the debt of industry to science in the development of its motive powers applies here equally in transportation. Permit a single illustration further of the value of pure science in the evolution of the circulatory system. Every engineer is aware of the large contribution which the steel rail has made to the success of the railway. Durable, strong and cheap, it has displaced on all our railways the weak and short-lived rail of iron. It has made possible heavier trains and higher speeds. Together with other factors it has so cheapened traction that, according to Professor J. J. Stevenson, the coal of West Virginia is now sold at New York City for less than one-fourth the railway freight charges of a quarter of a century ago. But it is no belittlement of the laurels of Sir Henry Bessemer, the inventor who has made all this possible, to point to the fact that the success of his process, which, by ushering out the Age of Iron, and ushering in the Age of Steel, has revolutionized industry and touched every home with its beneficence, is due not only to his use of a great body of facts in the chemistry of the metals, but in especial to the utilization by Mushet of the facts regarding the influence of manganese and its relation to carbon, facts ascertained in the laboratories of science and left on record to await their use by invention at the proper time.

The mobility in the social organism so largely due to science has had far-reaching effects. It stimulates production to the utmost. It opens the markets of the world to the products of every worker. Labor has itself become mobile, and in the factory raw material from distant lands meets operatives from across the seas. It is the cause of vast migrations, such as that which has brought to the United States more than nineteen and a quarter million people since the opening of steamship routes across the Atlantic. It makes impossible in civilized lands such famines as that which in 1878 in two of the northern provinces of China destroyed more than nine millions of men. It opens to the occupation of a single homogeneous civilized commonwealth such vast areas as the Mississippi valley. To any such it would be as fatal to stop the social circulation made possible by science, as in a limb of the body to ligate the main artery. Dense populations can indeed exist wherever food can be raised in abundance, as on the river plains of China, but without the modes of distribution introduced by the science of the nineteenth century, they neither can be unified into a homogeneous community nor can they be lifted to the levels of modern civilization.

By its systems of circulation which break down all barriers, science has brought about the supreme crisis in social and political evolution. Like the epeirogenic movements which mark the crises in geologic history, which united continents and precipitated alien upon indigenous fauna, science has brought civilization and barbarism the world over in all their stages to meet in a life and death struggle, and offers to the fittest the prize of a world-encircling empire.

The fact that in order to operate the railway it is necessary to send signals at greater speeds than those of moving trains, suggests another service of science—the highest material service which it renders the common weal. In the telegraph and telephone a system is supplied for the almost instantaneous transmission of motor and sensory impulses throughout the body politic. In general terms we may compare the growth of the communicating system of society to the development of the nervous system in the history of animal life, where the scattered central cells of nature's first sketch of such a system are later gathered into ganglia, and ganglia massed into a brain connected with every part of the body by ramifying nerve filaments. Of all social

organs this seems the most retarded in its evolution. In primitive society it is only the smallest groups, such as the family and the village community, which have a facility of communication comparable with that of the lowest of the metazoa. In the larger groups of the tribe and nation we find a stage more advanced than that of the hydra only after science has made possible the railway post and the telegraph and telephone.

That Morse is the inventor of the electric telegraph is a statement more veracious than that of the Vermont farmer who said that everybody knew that Edison invented electricity. But the name of the inventor of every tool of society is legion. Morse set the keystone of the arch, but its voussoirs had been built by investigators unknown to popular fame in many lands, and even the keystone was almost placed in the hands of the distinguished inventor by Henry, the great physicist. And Oersted, who in 1819 deflected the magnetic compass by a voltaic current in a neighboring wire; Arago, whose experiments with iron filings proved that this current would generate magnetism; Ampère with his suggestion of the possibility of signaling at a distance by the deflection of needles; Sweiger, who took up Oersted's experiment, and discovered that the deflecting force of the current was increased when the wire was coiled about the magnet; Sturgeon, who, making use of Arago's discovery, replaced Sweiger's magnetic needle with soft iron and thus constructed the first temporary or soft magnet; Henry, who strengthened the electro-magnet and used it with over a mile of wire to give signals by tapping a bell—all of these men, devoted solely to knowledge for knowledge's sake, are sharers with Morse and Vail in the glory of the invention of the telegraph.

And so with wireless telegraphy. In Marconi's hand this invention blazes with a sudden brilliance which attracts the attention of the world, but the torch has been conveyed to him along the line of many runners in the torch race of scientific discovery. From Clerk Maxwell, who showed the analogy between electricity and light; from Hertz, with his demonstration of electromagnetic waves; from Onesti of Fermo, and Branly of Paris, and Lodge of London, whose researches produced in the coherer an instrument capable of seeing such waves; from these and others the torch was passed on to the great inventor whose improvements in apparatus made effective the discoveries of science.

In the telephone at least four scientific principles are involved—the voltaic current, the interaction of magnetism and electricity, the temporary magnet and the microphonic action of carbon. Through this marvelous invention each master in electrical science from the time of Galvani who has aided in the elucidation of these principles, though dead, yet speaketh.

Thus we may fairly claim that to science is due in large measure the plexus of post, telegraph and telephone, by which intelligence is flashed throughout the body social even more swiftly than along the nerves of the body physiologic. And how incalulable is the service which science thus renders! Consider the extent of the channels of communication. The domestic mail service of the United States requires each year twenty-one million miles of travel. Sixty-four years ago the first commercial telegraph was built with a length of forty miles. At the close of the century there are not less than one million miles of telegraph in the United States, over which duplex and multiplex messages are carried at the same time, and the rate of transmission has risen to six thousand signals per minute. One hundred and seventy thousand miles of submarine cables moor coasts, islands and continents together. Over one million

miles of telephone wires have already been strung in our own country. Boston, a typical city, measures its electric nerves at a total of one hundred and seventy million feet, and the radius of audible speech from it reached a year since, according to Iles, to Duluth, Omaha, Kansas City, Little Rock and Montgomery.

Note the saving of time and energy thus accomplished. Without leaving his desk the manager of a business is in instant communication with all his employees, and with the business enterprises in his own and other cities. The captains of industry are thus able to command armies of a size unthought of a few decades since. So accurate and instant are the new motor and sensory nerves that the oil refineries, the copper mines, the steel mills, almost any industry that may be mentioned, can be regimented under one control, and an industrial revolution is accomplishing before our eyes.

The electric wire with the fast mail and the newspaper flash the news of the world throughout all civilized countries. When our army attacks Santiago or marches on Pekin, the public becomes impatient of even the interval between the morning and the afternoon paper. On the night of a national election the American public listens to the count of votes in every city and in every State. The new discovery of science, the new mechanical process, the new remedy for disease, are communicated without delay to the entire world. In commerce local prices seek the level of the world market, and the entire distributing system is as effectively controlled as are the capillaries of the animal body by the clutches of the nerves. In a theater vast as the whole earth we look down on the stage upon which is played the never-ending drama of current history.

In a still larger sphere the new organ of communication has a reflex on civilization. It makes possible self-governing communities stretching from the Atlantic to the Pacific and even the federation of the world. Bringing Washington face to face with London, Paris and Berlin, and the other capitals of Europe, it enables the great powers of two continents to arrange without delay a concert of action whose message flashes round the planet and is carried into effect at Tien Tsin and Pekin. In direct contrast unscientific China outspreads her bulk like some vast insensate vegetal growth. Under attack, even at a vital point, she can neither mobilize her armies nor even disseminate a knowledge of the danger before it is too late.

It has been said by Giddings that objectively viewed progress is an increasing intercourse, a multiplication of relationships, an advance in material well-being, a growth of population, and an evolution of rational conduct. Subjectively it is the expansion of the consciousness of kind.*

In all these respects science has been an accelerating force in the evolution of society. Increasing food supply by means of scientific agriculture, lengthening life by the repression of diseases, and introducing a thousand new means of livelihood, it has made possible the extraordinary recent growth of civilized nations. It permits the population of Europe to more than double since 1800, and enables England, which in the seventeenth century men thought too small for its scanty population, to support more than 38,000,000 people in comparative comfort. It lends some encouragement to the sanguine prophecy of Albert Bushnell Hart that the Mississippi valley will sooner or later contain a population of 350,000,000.†

At the same time science has produced a heterogeneity of structure. The scientific principle discovered to-day flowers to-morrow in invention and produces the seeds of

* 'Principles of Sociology,' New York, 1896, p. 359.

† 'The Future of the Mississippi Valley,' Harper's Mag., Vol. 100, p. 419.

special arts and crafts. To Volta's researches in his villa on Lake Como five million men now employed in the many various arts connected with electricity owe in a measure their livelihood. In promoting the development of the complex organs of society for the handling of energy, for distribution, and for communication, science has constantly been a differentiating force.

By the same means it is accomplishing a more and more complete integration. The separate life of primitive society, the old personal independence, is gone. In the new order all social units and aggregations are interdependent. We are all members of one body. We must not ignore the purely psychic factors of social progress, but these alone could not maintain the new order apart from the physical basis built by science, itself a psychic factor. Were this support withdrawn, it would seem that over large areas now occupied by civilization, society must lapse and break into fragments fast degenerating into the state of the villages of the Russian plain, the scattered communities of the southern Appalachians or even to the pueblos of Arizona.

As we have spoken of the service of science in promoting the physical well-being of society, there remain of Professor Giddings's notes of social progress only the evolution of rational conduct and the consciousness of kind. These phenomena are involved in the evolution of the social mind. Here science acts directly and also by the reflex of the social organism. The organic unity of society is the ground for the expansion of the consciousness of kind. The social ties woven by science help to produce a wider social sympathy. Under the régime of science the barriers of the mark break down everywhere to make way for the market, and with their downfall the provincialism, indifference and hate of once separated peoples pass away. Science has created, as we have seen, a new physical environment which reacts constantly on the social mind, awakening from torpor, stimulating to greater activity, demanding a more alert attention, and a precision and swiftness of movement before unknown.

Still more directly is science creating an intellectual milieu whose influence on the social mind is as inescapable as is that of climate on the physical life. The world of our forefathers, how close its confines, how dark and shadowy, how uncertain and untrue, compared with the illimitable sphere which science now fills with her clear light. It is a universe, not a multiverse, the new world which science apperceives. It is a world of law, in which each event has adequate cause; the expression of one immanent energy operating across all widths of space and throughout all lengths of time, without loss or increment, and without variableness or shadow of turning; an eternal becoming an evolving order which comprehends the growth and decay alike of solar systems and of the humblest of living creatures. It is of this new world that the two master Victorian poets, inspired by both the scientific and the religious spirit, have written:

> All's law, but all's love.

and,

> One God, one law, one element,
> And one far off divine event
> To which the whole creation moves.

The effect of these new cosmic conceptions of science penetrates every department of learning and every field of life. It revolutionizes society. It rationalizes the social mind. It has swept to the limbo of things that are not the sprites of evil which affrighted our forefathers. In this science has done a work which neither literature nor art nor religion nor ethical culture has proved itself able to accomplish. It was the pious Melancthon, the gentle scholar of the Reformation, who at Heidelburg saw in falling stars only the paths of

deceitful devils, and the mandarin to-day, learned in all the ethical wisdom of Confucius, a classical scholar of the finest literary taste, still burns his firecrackers at the funeral of a friend that he may frighten away the pestiferous spirits of evil which dog the steps of men through life even to the threshold of the world beyond.

The rationalizing influence of science upon civilization needs no illustration to one versed in the literatures of the prescientific ages, to one who has read Plato's 'Timæus' or Plutarch's description of the moon. And how preposterous were the theories current but a century since, such as those which saw in fossils the freak of some plastic power in nature or the remains of a catastrophe which swept away in a flood of waters the very foundations of the earth. To-day how rare and how interesting are such survivals of this almost forgotten time as the Atlantis of Ignatius Donnelly!

The theory of evolution furnishes one of the best examples of the replacement of the untruths of the past by truths discovered by science, and of their revolutionary effect. Since the discovery of the proofs of this process, man has come to know himself as never before. He understands at last the meaning of history and rewrites his texts on philology, literature and all social and political institutions. He sees, though as yet dimly, some solution to the ethical problems of sin and evil, and beholds as in a panorama the process of his creation.

It is as yet too soon to see the full effect of these new conceptions upon the social mind. Science has not yet come to its own in education, and the irrational and the unreal are far from being wholly banished from society. But more and more the care of the young is entrusted to science to train, as none other can, to be quick of eye, true of speech, and rational in thought, to bring them face to face with reality and to open to their view the widest and most inspiring vistas. Common knowledge is one of the strongest social bonds. We meet and touch in what we know. The time has been when educated men drew together in a common knowledge of phrases written in extinct languages. To-day they find this rapprochement, this consciousness of kind, more and more in a common training in science. In the laboratory they have measured the energy of the falling body and studied its transformation into sound, heat, light, chemism and electricity; they have tested the ray from the hydrogen atom and found its vibration the same from the flame on the table and in the light of Sirius. They have dissected the tissues of life, and have read in Nature's book the life histories of mountain, river and planet. And thus to-day they have attained to that cosmic conception, overwhelming in its sublimity, which is the best gift of science to man.

The reward which science asks for this service is the wages of going on; she asks for well-equipped laboratories, for longer courses of scientific study in schools, for the endowment of scientific instruction and research. Such foundations as the Lawrence Scientific School, the Field Columbian Museum, and the Smithsonian Institution are examples of appreciation as yet as rare as munificent. I am not aware of any such in Iowa. When wealth builds the spacious laboratory or endows a chair in science in any college of the commonwealth, it is but rendering to science her own. Each dollar earned by railway, telegraph and telephone, mine and quarry, mill and factory, farm and store, may well pay tithe to science which has made these industries possible. The gratitude for a life saved by the applications of science in modern medicine might well be generous. And yet the total gifts to scientific instruction in Iowa by men of wealth do not exceed $50,000. I am aware of the State appropriations to the

scientific departments in our State institutions, and I should be glad to call them generous. At least they have given Iowa the fame of men whose work in science has achieved national recognition. But these yearly appropriations, were they many times as great, could not supply the place of the great gifts, endowments to be for all time reservoirs of power transmuted constantly into the highest social service. It is the boast of American democracy that by such votive offerings it shows appreciation of education, charity and scientific research.

As members of a guild of workers in science, let us be thankful for even the humblest place. To discover any fact, however trivial, to add anything, however slight, to the sum of human knowledge, this is to shape and dress some stone for the building of science, the home and shelter of the race. Our contribution may go to chink some crevice, or at least some master builder may find in it the keystone of an arch or the cap stone of a column. But whatever its place, if our work was well and truly done it abides as a permanent service to society.

William Harmon Norton.
Cornell College, Mt. Vernon, Ia.

A NEW CONNECTION BETWEEN THE GRAVITY MEASURES OF EUROPE AND OF THE UNITED STATES.

Absolute measures of gravity, repeated by different observers using different instruments at identical stations, have shown comparatively large disagreements. The general experience has been that differential measures of gravity are much more accurate than absolute measures, and there has, therefore, been a growing tendency to use the differential method rather than the absolute method. The results of such differential measures may be reduced to absolute units either by connecting by the relative measures many stations at which absolute measures have been made and then making an adjustment to get a mean value, or a single determination of the absolute value of gravity, which is believed to be of a much higher degree of accuracy than any other, may be used in reduction to absolute units.

These general conditions, especially with respect to gravity stations in Europe and the United States, led naturally to the campaign of differential gravity measures carried out by Assistant G. R. Putnam, of the Coast and Geodetic Survey, in the summer of 1900, under the direction of the International Geodetic Association.

The compact and portable half-second differential pendulums known as A4, A5 and A6, and of the type developed under the direction of Dr. T. C. Mendenhall while he was superintendent of the Coast and Geodetic Survey, were swung at Washington in May and again in October, 1900. Between these dates they were also swung at the Kew University, Greenwich Observatory, London Polytechnic Institute, Paris Observatory and at Potsdam, Germany, and thus served to determine with considerable accuracy the relative values of gravity at these points. Some of the principal previous determinations of gravity which have been made at or near these stations, and are therefore connected by the observations of 1900, are at Washington, by Preston in 1889–90, and Defforges in 1893; at the Kew Observatory, by Heaviside in 1873–74, by Herschel in 1881–82, by Walker in 1888, by Von Sterneck in 1893; at Greenwich Observatory, by Von Sterneck in 1893; at the London Polytechnic Institute, by Sabine, Kater and Herschel; at the Paris Observatory, by Defforges in 1892, and Von Sterneck in 1893. At Potsdam the observations connect with a most elaborate and painstaking determination of the absolute value of gravity which is now in

progress under the direction of the International Geodetic Association, and which is expected to yield the most reliable value ever yet determined in absolute units.

Other connections of varying degrees of accuracy had previously existed between these six stations. The new measures furnish direct connections of a very high degree of accuracy. These six stations have directly or indirectly been connected by various observations with nearly all the gravity stations of the world.

The work of deducing from the numerous connections between the gravity measures of various countries the best absolute values of gravity at the many points of observation scattered over the whole globe is peculiarly the duty of the International Geodetic Association, and is being performed systematically by that organization. In this investigation the gravity observations of 1900 furnish important new evidence.

The special value of these gravity measures of 1900 to the Coast and Geodetic Survey lies in the fact that they furnish the means of reducing accurately to absolute units all the relative measures made in the United States with the half-second pendulums during recent years. These values have up to the present time been reduced approximately to absolute units by assuming that the value of gravity at the Coast and Geodetic Survey Office is 980.098 dynes. This approximate value was adopted in 1892 and depends upon an absolute determination of gravity at Hoboken, N. J., and three comparisons of Hoboken with Washington by relative measures with three different sets of pendulums, and finally an absolute determination at Washington in 1889–90. In 1894 Mr. Putnam derived twenty-nine different values for gravity at Washington by utilizing all the connections available at that time between Washington and various stations at which absolute measures had been made by various observers from 1792 to date. The mean of these values was 980.107. As the individual determinations showed a wide range, 0.147, the value 980.098 cited above was retained. From the relative observations of 1900, combined with the preliminary published absolute value of gravity at Potsdam from the observations which are still in progress, the value of gravity at Washington is 980.111. This differs by one part in 77,000 from the approximate value adopted in 1892, and by only one part in 250,000 from the mean of the 29 values deduced in 1894.

JOHN F. HAYFORD.

THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

THE first conversazione of the Institute was held at Columbia University on the evening of April 12th. About 1,500 ladies and gentlemen attended and enjoyed a most pleasing entertainment. Through the courtesy of the University authorities every facility in the way of space, current supply and assistance in preparing exhibits was placed at the disposal of the exhibitors, so that the many new devices, etc., were shown in actual operation. The list of exhibitors was long and the character of the apparatus extremely varied, as might be expected from a function held under the auspices of a society which represents the connecting link between pure science and commercial engineering. Many of the names included are well known in scientific circles, but the exhibits were in every case novel and have created a standard which will tax the energies of the Institute to the utmost to repeat in future conversaziones. Many notable persons were present as guests of the Institute, among them President Low and numerous professors of Columbia. President Low was accompanied by Baron von Holleben the German Ambassador to this

country. Mr. Thomas A. Edison was among the distinguished electricians present, while a great number of colleges were represented by exhibitors and guests, Vassar sending a contingent of a dozen students interested in natural science.

Dr. Michael I. Pupin exhibited the original apparatus used in developing the recent invention for the improvement of long-distance land and ocean telephony which has recently been bought by the American Telephone Company. Mr. Peter Cooper Hewitt showed numerous samples of his recently invented high efficiency lamps. In these lamps mercury vapor is used instead of a filament, the lamp consisting of a long, cylindrical glass tube. At the bottom of each is some mercury, from which, when the current of electricity has passed through it, issues the vapor and a most peculiar colored light is emitted. It is half purple, half green. This is a disadvantage, but it can be obviated by the use of counteracting colored shades. In a room near the Hewitt lights were the akouphone and akoulalion invented by Mr. M. R. Hutchison. They are microtelephonic instruments, so constructed as to reproduce and intensify sounds and still preserve their quality, and many successful experiments were made upon deaf mutes, in which they were taught many new words during the evening. One of the largest lecture rooms of the university had been set aside for the use of Mr. Nicola Tesla, where he showed numerous interesting experiments with high-frequency currents.

Much interest was shown in the exhibit of European Nernst lamps, made by Mr. William J. Hammer, who also showed Weldemar Paulsen's new telephonograph and telegraphone, loaned by Lemvig Fog and Emil S. Hagemann of Copenhagen, Denmark.

These instruments receive telephone messages in the absence of the recipient and record them on a kind of magnetic phonograph, which repeats them when the one for whom they are intended returns.

Another exhibit of Mr. Hammer's was a collection of aëronautical pictures, comprising photographs of Professor S. P. Langley's aërodrome, Sir Hiram S. Maxim's flying machine, Santos-Dumont's dirigible airship, and Count Zeppelin's balloon; together with the balloon tests made during the Aëronautical Congress, at the Paris Exposition of 1900, and by the Aëro Club of France. Most of these photographs were taken by the exhibitor. Prof. S. P. Langley exhibited his latest form of bolometer for spectrum analysis and showed many drawings and diagrams of the principles and results obtained.

Professor W. S. Franklin exhibited a magnesia arc lamp, an electrolytic lamp on the Nernst principle, operating on 1,000 volts.

Professor Francis C. Crocker showed magnetic liquids, with apparatus in operation for showing the magnetic properties of liquids and for measuring their permeability, and Mr. Martin P. Rice, a new X-ray apparatus employing a modified form of Wehnelt interrupter. Radiographing of alternating currents was shown in a large room which could be darkened at will. The exhibitors were Professor Harris J. Ryan and Professor J. O. Phelon, and their method secured stationary and continuous diagrams of alternating current values by records made from the radiographs of a rapidly rotating cathode ray, the rotation being caused by the action of the current.

Professor Elihu Thomson had a most interesting exhibit consisting of a dynamo static machine and a new rotary electrical apparatus. The former contained a small direct-current motor, the windings of which were tapped and connected to two rings, giving a primary alternating current for the operation of a step-up transformer which gave a secondary current of about 20,000

volts, being capable, however, of regulation through a wide range. The tops of the alternating current waves of high potential obtained from this secondary transformer were used to charge a number of glass plate condensers in parallel. The rotating frame synchronously driven with the motor made the connection to the condensers periodically and in synchronism with the alternating current. The connection by the rotating frame is alternately in parallel and in series, the condenser plates being charged to 15,000 volts with ten in parallel, giving 150,000 volts when connected in series. The machine therefore furnishes from low pressure direct current, high potential discharges of definite polarity at the discharged terminals. The new rotary electrical apparatus consisted of an iron sphere heavily electroplated with copper and mounted so that it may revolve on any axis or in any plane. Surrounding this sphere were three coils in planes at right angles to each other. By suitably energizing these coils with polyphase current the sphere was made to revolve on any axis or in any direction, thus illustrating a three dimension polyphase system. This apparatus shows in a very satisfactory manner the principles of the gyroscope and Bohnenberger sphere.

Professor Thomson also exhibited an aluminum disc mounted on a shaft free to rotate, and having applied to it in special ways alternating current magnetic fields, the rotations of the disc involving interesting paradoxes which the visitors were asked to explain.

Mr. E. V. Baillard showed the Parker-Baillard bridge for measuring low electrical resistances for general work and standardization and an ingenious faradmeter for the direct measurement of capacity. Some interesting spark experiments, showing oscillating discharges occurring rapidly during the same half wave, and proving that a short circuit in a high potential current containing inductances and capacity ruptures itself instantly, were shown by Mr. W. S. Andrews who also exhibited a luminous aluminum cell giving beautiful effects.

Among the many other exhibits were various forms of storage batteries by Mr. Elmer A. Sperry, Mr. Herbert Lloyd, Mr. A. S. Hubbard and Messrs. Frank Perret, J. A. Barrett, and W. H. Meadowcroft. Mr. H. R. Palmer showed a fac-simile picture telegraph in operation, Mr. Otto T. Louis an electric furnace and an ohmmeter. A specimen of the standard United States Army field telephone and telegraph kit used in the Cuban and Philippine campaigns, and wireless telegraphy as improved by the Government, were in charge of Col. Samuel Reber, U. S. A.

W. C. ANDREWS.

SCIENTIFIC BOOKS.

Erinnerungen aus meinem Leben. Von A. KÖLLIKER. Leipzig. 1899. 8vo. Pp. x + 399.

This work of the veteran celebrated histologist is much more than an autobiography, since it includes a number of original contributions to science, with which the anatomist and embryologist must necessarily acquaint themselves.

The first part is strictly biographical, giving a general account of the author's life, which passed without exciting elements along academic paths. Kölliker was born at Zürich, in Switzerland, on July 6, 1817, the elder of two children. He dwells somewhat upon the recollections of his boyhood, recalling with pleasure a few boyish escapades. He early displayed great fondness for nature; he loved the mountains and made collections of plants and minerals, and therefore was led naturally to the study of medicine. But practice had no allurements for him, especially since he soon fell under the spell of the microscope, as a revealing instrument, in the employment of which he has spent his long life. In the summer of 1839 he went to Bonn, hearing there medical lectures in Latin, and the autumn of the same year he passed to Berlin and came under the

direct influence of Germany's greatest morphologist, Johannes Müller, and of Jacob Henle. The latter brought him to the study of the microscopic anatomy of the human body, and so started him upon the career of investigations, which, sixty-two years later, he is still pursuing. It is an interesting coincidence that Kölliker's career began in 1839, the very year in which Schwann established the cell doctrine for animals, so that he has lived through the whole period of the application of that doctrine to the problems of morphology, physiology and pathology, and has, during this epoch, achieved the remarkable distinction of having contributed more than any other single investigator to our knowledge of the cellular structure of animals. It is difficult to realize how many of the fundamental facts of microscopic anatomy, even of those which have been taught in elementary text-books for forty or fifty years, we owe to the discoveries of Kölliker.

In 1841, he became assistant to Henle, who was then at Zürich. In 1844 he was promoted to be professor extraordinarius of physiology. The conditions at Zürich were unsatisfactory, so that in 1847 he accepted a call to Würzburg, where he has since remained, for over half a century. In 1848 he married Maria Schwarz, of Mellingen, in Switzerland.

The volume gives a list of the celebrations in which the author took part, and a list also of all the medals, prizes and other honors which have been bestowed upon him. There are also accounts of his journeys, several of which took him to the sea-shore for purposes of research. The accounts are chiefly in the form of letters, written at the time, and they include a great number of interesting impressions of famous scientific men which offer valuable material for the history of science during the century.

There are three portraits of the author—that which forms the frontispiece is an admirable likeness of the handsome and intellectual face. Another full-page illustration is a photograph of the carved box which was made for the congratulatory address presented to Kölliker on his eightieth birthday.

The second part of the work enumerates his activities as a university teacher and administrator, including the various courses of lectures he has delivered. Next follows the annotated catalogue of his publications, classified with considerable care. The annotations are often explanatory of the origin and purposes of the separate publications and of the standpoint of the author at the time. Other notes define the share of an essay in developing and fixing scientific conclusions. Finally one encounters, apropos of several articles in the catalogue, additional new observations recorded, which serve to correct and amplify the original record. Some of these observations are illustrated by new figures also. In brief, there is scientific matter included, which is here published for the first time.

Kölliker's 'Erinnerungen' is different in many respects from the usual autobiography, but is certainly a remarkable contribution to the record of the general condition and progress of science during the second half of last century.

CHARLES S. MINOT.

The Bird Book. By FANNIE HARDY ECKSTORM. Boston: D. C. Heath & Co. 1901. 12mo. Pp. xii + 276; 24 pls., map, and 31 figs. in text.

The Woodpeckers. By FANNIE HARDY ECKSTORM. With Illustrations. Boston and New York: Houghton, Mifflin & Co. 1901. 12mo., pp. viii + 132; 5 col. pls., 21 figs. in text.

The time was, not many decades ago, when the young student of ornithology was, of necessity, self-taught, learning almost wholly by his own unaided observation in the field. Nowadays the demands of a multitude of would-be learners for short and easy paths to knowledge have led to the making of many books, that serve, at least, to show how hard it is for books alone to give the beginner the training he needs. How to observe carefully and thoroughly, and how to interpret what one sees, are not readily learned, except by the hard school of experience.

In these two volumes Mrs. Eckstorm has to a remarkable degree succeeded, where some of her predecessors have failed, and surely has gone far toward accomplishing the seemingly impossible. Even abstruse technicalities and fundamental biological principles are stated so clearly and simply that a child easily may com-

prehend them; and the details of bird life are so told that the reader cannot fail to gain an idea of what things the experienced naturalist looks for, and what he sees.

'The Bird Book' is divided into four parts. A dozen or so descriptive sketches under the title 'Water-birds in their Homes,' are followed by explanations of such matters as the structure, mechanism and use of birds' feet, wings and bills, and the adaptation of their different forms to habits. Then other, more philosophical subjects are unfolded, and made surprisingly plain, such as the principles of classification, the conditions of the struggle for existence, distribution and migration; and the concluding chapters are devoted to detailed accounts of some habits of birds, as 'How the Hawk Eats his Food,' 'The Cave Swallow's Changes in Nest-building,' 'How the Shrike Hunts.'

'The Woodpeckers' is, in form, more a popular monograph of that group of birds. After several chapters on the habits of woodpeckers in general, five widely distributed and representative North American species are taken up in turn, and the characteristics of each discussed. Following this, the peculiarities and uses of the woodpecker's bill, foot, tail and tongue are studied, and then attention is drawn to the modifications of these organs in different genera and to their remarkable adaptation to the specialized habits of each. The volume is concluded by a key for the identification of all the North American woodpeckers.

The books are well written. The style is never dull, and often brilliant. They are abundantly and, on the whole, well, illustrated; and 'The Woodpeckers,' in addition to various figures in the text, contains five colored plates.

It should be added that throughout both volumes the author is remarkably successful in carrying out their evident underlying purpose —not merely to convey information and inspire interest, but to cultivate in the beginner, by example rather than precept, a truly scientific spirit, both in his observations and in his deductions.

C. F. B.

Engineering Chemistry, a Manual of Quantitative Chemical Analysis for the Use of Students, Chemists and Engineers. By THOMAS B. STILLMAN. Second edition. Easton, Pa., The Chemical Publishing Co. Pp. 22 + 503. Price, $4.50.

The first edition of this book appeared in 1897. Its usefulness is indicated by the fact that a second edition is required so soon. The work seems to be designed to serve several purposes. The first portion, especially, appears to be intended for the use of students beginning the subject of quantitative analysis. The exercises selected in this portion are satisfactory, but the directions lack that careful detail in regard to methods of manipulation and in regard to the properties of the compounds used in analysis, which are so necessary for the student who is to acquire any adequate knowledge of the subject. It may be objected, of course, that room could not be found in this book for such details. It would seem, however, that these exercises at the beginning should have been omitted altogether or they should have been properly given.

The chemist or student who has already acquired a knowledge of analytical methods will find very much throughout the book that will prove very useful. The subjects discussed cover a wide range, the more important being the analysis and filtration of water, the analysis of coal, gas and other fuels, calorimetry, iron and steel analysis, blast furnace charges, analysis and tests of cements, analysis of clay, alloys, paper, soap, oils, paints and asphalt, pyrometry, electrical units and energy equivalents.

The writer is well aware of the large amount of labor which an author must give to the study of the literature of each topic in writing a book of this kind, in order to determine what is the best present analytical practice, and some mistakes are to be expected. In several cases, however, it would seem that better methods or more accurate directions might have been easily found. Thus, under coal analysis, in giving Eschka's method for sulphur, nothing is said about the danger of absorption of sulphur from an ordinary gas flame; for phosphorus in steel the method of Dudley and Pease is given, although that method has since been modified in several important particulars, and made more accurate without increasing the time required for its execution; for total carbon in iron, solu-

tion with the use of neutral copper sulphate is recommended instead of the acid solution of the double chloride of potassium and copper, which has been shown to be more exact by the American Committee on Standard Methods.

With revised tables of atomic weights, published annually by both the American and German Chemical Societies, it seems hard to find an excuse for a list which includes such values as Al, 27.5; Mg, 24.0; Si, 28.0; Cr, 52.5; Zn, 65.0. Antiquated values are also given for the specific gravity and weight of one liter of hydrogen.

While defects in the book have been pointed out at some length, it would be unfair not to refer to the large amount of valuable material to be found in its pages.

The frequent tables of analysis for commercial products give, in concise form, directions which will be very useful to the working chemist. The specifications for many substances used by railroad companies form a unique and excellent feature. And, while pyrometry, electrical units and energy equivalents do not properly belong in the domain of chemistry, many chemists will find them useful.

W. A. NOYES.

Ausgewählte Methoden der analytischen Chemie. Von PROFESSOR DR. A. CLASSEN. Erster Band unter Mitwirkung von H. Cloeren. Braunschweig, Friedrich Vieweg und Sohn. 1900. 18mo. Pp. xx + 940. Figs. 78. Price, M. 20.

Notwithstanding the astonishing number of books bearing upon analytical chemistry which appear yearly, it is probably within bounds to say that, until recently, only those of Fresenius, Böckmann, Bolley, Post, and possibly that of Crookes, have generally been regarded as fulfilling the requirements as to scope and reliability of a satisfactory book of general reference. In the last few months, however, three works of wide range and excellent promise have appeared—namely, those of Carnot ('Traité d'analyse des substances minerales'), Lunge ('Chemisch-technische Untersuchungs-methode') and this work of Classen. Classen's work differs, however, from those of Lunge (a continuation of that of Böckmann), Bolley, and Post, in that he presents his subject matter in such a way as to emphasize rather the general usefulness of the methods described than to present schemes for the analysis of particular bodies, although the application of the methods to special cases is adequately treated. On the other hand, Classen's work differs from those of Fresenius and Carnot, in that he has prepared the book for the use of technical chemists and advanced students to whom the general operations of analytical chemistry, such as weighing, filtering, and the like, are known. These are, therefore, omitted, and he proceeds at once to the description of particular methods.

The present volume includes only the metals and metalloids. Methods suitable for the qualitative detection of each are described, followed by procedures for their quantitative determination by volumetric, gravimetric, colorimetric or electrolytic methods, the selection having been determined upon, he states, only after tests made by him, his assistants or pupils, or, in some instances, after he had become convinced of the accuracy of the processes through published criticism. The descriptions of the procedures for the determination of the metals are, in turn, followed by those of methods for such separations from other elements as occur in ordinary analytical practice, and, in addition to the foregoing, special schemes are given for the analysis of bodies of technical importance, such as irons and steels, aluminum and its alloys, cements, clays, glasses, zinc ores and zinc dust, chrome iron ore and chrome steel, uranium ores, platinum ores and residues, 'osmiridium,' 'platiniridium,' fertilizers, liquid ammonia, ammoniacal liquors, and a scheme for rock analysis.

The value of this book as a work of reference is also much enhanced by the introduction of matter relating to the rarer elements. The methods described for the separation of the rare earths by fractional precipitation and the analysis of monazite sand, as well as of the materials employed in the manufacture of mantles for incandescent lamps, appear to be specially complete.

The author deplores the general absence in text-books and journals of statements indicating the basis of the stoichiometrical calcula-

tions often required in connection with the analytical operations described, and has, wherever these calculations are at all complicated, indicated the method of procedure. Tables to assist in the calculation of analyses are also appended.

References to the original sources of information are uniformly and freely given. Many of these refer to articles published in 1900, indicating that the book has been brought well up to date. The book closes with an excellent subject and author index, and the typography throughout is very satisfactory.

Professor Classen presents, as a product of thirty years of analytical practice in connection with technical chemistry, a work which bears evidence of a high degree of trustworthiness and is, to the extent to which it has been finished, of an unusual degree of completeness. As would have been expected, considerable stress is placed upon electrolytic methods and their advantages, and the omission of certain methods which are known to be reliable may cause some surprise; but there can be no doubt that the work is a distinctly valuable addition to the literature of analytical chemistry, and is sure to be of great service. Its early completion is much to be desired.

H. P. TALBOT.

SCIENTIFIC JOURNALS AND ARTICLES.

IN the February–March number of the *Journal of Geology* Thomas L. Watson discusses 'The Origin of the Phenocrysts in the Porphyritic Granites of Georgia.' Detailed descriptions of the rocks of various districts are given. The criteria for distinguishing phenocrysts formed *in place* from those of intratelluric origin are stated and the conclusion is drawn that these were undoubtedly formed in place. Under the title of 'Certain Peculiar Eskers and Esker Lakes of Northeastern Indiana,' Charles R. Dryer describes some interesting results of deposition by glaciers or glacial waters which he does not attempt to fully explain. Good contour maps are given which, with the data furnished, will bear study. 'Correlation of the Kinderhook Formations of Southwest Missouri' is discussed by Stuart Weller. A recent State report makes a part of these rocks Devonian and supposes the section to be poor in fossils. Mr. Weller has collected many fossils from the area and gives in detail the evidence upon which he definitely correlates all the beds with the Chouteau limestone of central Missouri which is Upper Kinderhook. F. W. Sardeson concludes the discussion of 'The Problem of the Monticuliporoidea' begun in the last number. O. C. Farrington contributes a second article on 'The Structure of Meteorites,' giving a detailed description of the chondritic structure. An interesting conclusion gives an account of the synthetic experiments by which it has been attempted to reproduce the structural details of meteorites. Success in this line has not been marked, and it may be necessary to fall back upon extra-terrestrial conditions. The intense cold of space is suggested.

IN *The Auk* for April P. B. Peabody describes the 'Nesting Habits of Leconte's Sparrow,' and William Brewster notes 'The Occurrence, in Massachusetts, of Certain Rare or Interesting Birds,' and Frank Coates Kirkwood tells of 'The Cerulean Warbler (*Dendroica cœrulescens*) as a Summer Resident in Baltimore County, Maryland.' Joseph Grinnell describes 'Two Races of the Varied Thrush' and J. Lewis Bonhote has some notes 'On a Collection of Birds made by Mr. T. R. Thompson at the Cay Lobos Lighthouse, Bahamas'; and Otto Widmann contributes an article on 'A Visit to Audubon's Birthplace,' Fontainbleau Plantation, near Mandeville, La.; the house is now in ruins. Reginald Heber Howe, Jr., has 'A Study of the Genus *Macrorhampus*' deciding that *M. scolopaceus* is but a subspecies of *M. griseus*. H. W. Henshaw notices 'Birds of Prey as Ocean Waifs,' and Francis J. Birtwell gives 'A Description of a Supposed New Subspecies of *Parus* from Mexico.' Hubert Lyman Clark discusses 'The Pterylosis of *Podargus*, with Notes on the Pterylography of the Caprimulgi,' concluding that the nearest relatives of this group of birds are to be sought for among the nocturnal birds of prey. There is a 'Republication of Descriptions of New Species and Subspecies of North American Birds, No. II.' by J. A. Allen, Wilfred H. Osgood describes

'New Subspecies of North American Birds,' and Leonhard Stejneger considers 'The Two Races of *Saxicola œnanthe*.' There is a large number of interesting General Notes, reviews of Recent Literature and Notes and News.

Bird Lore for March–April opens with an article by Frederic A. Lucas on 'Walrus Island, a Bird Metropolis of Bering Sea,' with some reproductions of fine photographs by H. D. Chichester. Mrs. Harriet Carpenter Thayer tells of 'Our Blue Jay Neighbors,' with illustrations from photographs by Thos. S. Roberts; F. A. Van Sant has a brief paper on 'Early Larks,' and P. B. Peabody another on 'Saw-whet Homes.' In the third series of 'Birds and Seasons' the theme is treated by various well-known ornithologists, the birds being those for April and May. Elizabeth Hoppin Lewis contributes for young observers an illustrated poetical 'A B C of Bird-Lore.' There are the usual reviews and the section devoted to the 'Audubon Societies.'

THE *Journal of the Boston Society of Medical Sciences* for February contains papers on 'The Relation Between Conductivity and the Inorganic Salts of the Nerve,' by Albert P. Mathews; 'Dermatomyosites, with Report of a Case which also presented a Rare Muscle Anomaly, but once described in Man,' by Walter R. Steiner, and 'The Effect of Carbon Dioxide and Oxygen on Smooth Muscle,' by Allen Cleghorn, assisted by H. D. Lloyd. The remainder of the number is devoted to abstracts of papers presented at the second annual meeting of the Association of American Bacteriologists, in December, 1900. Among these we note one on the possibility of infection from the use of modeling clay in school work.

SOCIETIES AND ACADEMIES.

SECTION OF ANTHROPOLOGY AND PSYCHOLOGY OF THE NEW YORK ACADEMY OF SCIENCES.

A REGULAR meeting of the section was held on March 25th, Professor Cattell presiding. The annual election of section officers was held, resulting in the choice of Professor Livingston Farrand as Chairman, and Dr. R. S. Woodworth as Secretary.

Professor F. H. Giddings presented a paper on the use of the term 'race.' He spoke in part as follows: "The term 'race' as used by many different groups of investigators—anthropologists, ethnologists, philologists and historians—long since ceased to have a definite meaning. Efforts to establish a technical and conventional use of the word have thus far been unsuccessful. As one more attempt I suggest a combination of the word 'race' with various descriptive adjectives, denoting successive degrees of kinship. The narrowest degree of relationship is consanguinity, or the relationship (physiological, psychological and sociological) of father, and mother and children, brothers and sisters, grandparents and grandchildren, uncles, aunts and cousins. Let us designate this degree of kinship by K_1. The next degree of kinship, or K_2 is propinquity. The primary meaning of this word is 'nearness in place' and the secondary meaning is 'nearness in blood.' The word is thus perfectly descriptive of a state of facts which we find when a number of families live in the same neighborhood and, through intermarriage and association, become related (but less closely than the consanguini of K_1) in blood, in type of mind, and in institutions. K_3 is nationality, that wide degree of kinship (physical, mental and social) which includes those who speak the same language, and, for many generations, have dwelt together under the same political organization. K_4 is potential nationality, or the degree of relationship (physical, mental and social) of a heterogeneous people composed of many nationalities, undergoing assimilation, or blending, into a new nationality, as in the United States. Potential nationality includes the familiar census divisions, 'native born of native parents,' 'native born of foreign parents,' and 'foreign born.' K_5 is ethnic-race, a group of closely related nationalities, speaking closely related languages, and having well-marked psychological characteristics in common. Examples are the Celtic ethnic-race, including the Welsh, the Irish, the Highland Scotch, some of the Cornish and the Bretons; the Teutonic ethnic-race, including Germans, Swedes, Norwegians, Danes and Dutch; and the Latin ethnic-race, including Italians, Spaniards and Greeks; K_6 is Glot-

tic race. This is that very broad relationship, to a slight extent physical, to a somewhat greater extent mental and social, of those related ethnic-races that speak languages derived from a common ancient tongue. Examples are, the Aryan glottic-race, including the Celtic, Teutonic, Latin and other ethnic-races; the Semitic glottic-race, and the Hamitic glottic-race. K_7 is chromatic race, that extremely wide and vague relationship, which includes related glottic-races marked by the same color. Examples are, the white chromatic-race, which includes the Aryan, Semitic and Hamitic glottic-races; the yellow chromatic-race, which includes the various glottic-races known as Mongolian or Turanian; the brown, the red and the black chromatic-races. K_8 is cephalic-race, or that widest relationship which includes chromatic-races of like cephalic index. The distinction about which I feel most doubt is this between chromatic and cephalic race. Remembering that, according to this scheme, variability and multiplicity of specific characteristics produced by differentiation should increase as we proceed backward from K_8 to K_1, I think that probably cephalic index is rightly placed as K_8 and color as K_7 because, in the organic world in general, coloring seems to be a less stable characteristic than anatomical structure. The compound terms which I have here introduced are admittedly clumsy, but they have the advantage of conveying precise meanings. If a writer speaks of 'race' without a qualifying word, his reader must guess at his meaning. If he says, 'cephalic-race,' 'chromatic-race,' 'glottic-race,' the meaning cannot be mistaken."

In reply to a question Professor Giddings said that the clan is developed between K_1 and K_2 and the tribe between K_2 and K_3.

The following paper was read by Mr. Stansbury Hagar, on the 'Wards of Cuzco.' The speaker presented a portion of the evidence collected by him which tends to show that the twelve so-called wards of Cuzco, the ancient capital of the Inca Empire, were the terrestrial representatives of the signs of the Peruvian zodiac. The evidence bearing on this hypothesis is divided into four main classes. In the first place, the system of 'mamas,' under which the Peruvians regarded every material object as merely a product of the real spiritual essence of which it was the expression, gave rise to an attempt to imitate on earth the features of the world above as observed in the heavens. This system, in turn, resulted in the production of an elaborate ritual, the features of which, each month, corresponded with the supposed attributes of the 'mama' which governed the corresponding sign through which the sun was passing during that month. The ideas associated with the 'mamas' are shown to correspond with the names of the Cuzco wards. Again, these names correspond very definitely with the names of the zodiacal signs upon the native star map of Salcamayhua. And finally the names of one or two of the wards can be identified directly with definitely known native constellations situated in the zodiac. The nature of the evidence thus adduced is such as to indicate that the native Peruvians had made remarkable advance in astronomical knowledge in times long anterior to the arrival of the earliest Europeans known to history.

R. S. WOODWORTH,
Secretary.

GEOLOGICAL SOCIETY OF WASHINGTON.

AT the 113th meeting, held at the Cosmos Club March 27, 1901, the discussion of geological units begun at the preceding meeting was continued by Professors H. S. Williams, C. R. Van Hise, T. C. Chamberlin, and others.

At the 114th meeting, held April 3d, the following communications were presented:

The Priceite of Lone Ranch, Curry Co., Oregon: J. S. DILLER.

This chalky borate of lime occurs rather irregularly upon and in a mass of serpentine, and is probably a hot-spring deposit.

The Problem of the Archæan: C. R. VAN HISE.

An historical review of the progress made in differentiating pre-Cambrian rocks, and a statement of the present basis of distinction between Archæan and Algonkian.

At the 115th meeting, held April 10, 1901, the program was as follows:

The Philadelphia Gneisses: F. BASCOM.

A study of the petrography, structure, age and genesis of the gneisses in the vicinity of Philadelphia.

Possible Pre-Wisconsin Tills of Massachusetts: MYRON L. FULLER.

In the central portion of this country, the deposits of till have been differentiated into sheets of different ages, but in New England the severe glaciation of the Wisconsin Period removed, as a rule, all traces of earlier tills. Recently, however, a number of exposures have been discovered in the region south of Boston in which highly oxidized or disintegrated tills are found to underlie the ordinary light buff till of the Wisconsin ice invasion.

This lower till contains from two to four times the amount of clay contained by the Wisconsin till, is composed almost entirely of deeply decayed or disintegrated materials, is marked by the presence of the bright colors characteristic of advanced oxidation, lies upon deeply altered and practically unglaciated rock surfaces, has no far-traveled rock fragments, and is sharply separated from the overlying till both by its color and by its composition.

This older till is probably to be correlated with the Kansan or pre-Kansan till of the central portion of the United States.

The Waverly Group in Northeastern Ohio: GEORGE H. GIRTY.

In 1900 an effort was made to trace eastward into Pennsylvania the members of Newberry's Waverly section in northern Ohio. The Berea grit of the Waverly group was found to be the equivalent of the Cussewago sandstone of northwestern Pennsylvania. The Orangeville shale of that region is the basal third of the Cuyahoga shale, in part equivalent to Orton's Berea shale. The Sharpsville sandstone representing the middle portion of the Cuyahoga is probably the stratum producing the lower falls at the village of Cuyahoga Falls. The Meadville shale can with little doubt be correlated with the upper portion of the Cuyahoga, and it seems probable that the Shenango sandstone and shale are the equivalents of the Logan group. It is doubtful if the Corry sandstone is represented in Ohio, while the Bedford and Cleveland shales probably die out before reaching the Pennsylvania line.

F. L. RANSOME,
DAVID WHITE,
Secretaries.

CHEMICAL SOCIETY OF WASHINGTON.

THE 125th regular meeting of the Society was held March 14th. The following papers were presented:

'Notes on a New Indicator,' by E. G. Runyan. In this paper were presented results on the determination of total acidity in both white and colored wines, using as indicator an alcoholic solution of malachite green and commercial rosolic acid or corralin. For comparison, results obtained on the same samples with phenolphthalein and litmus were also presented. The data given seemed to be favorable to the use of the corralin-malachite indicator in titrating wines and similar colored products.

'The Action of Saccharin on Sugars and other Carbohydrates,' by L. M. Tolman. The author stated that saccharin was being sold as a substitute for sugar, and that it was sometimes found mixed with cane sugar. The best method of determining the saccharin present is the Reid method, by which the saccharin is hydrolized to the acid ammonium salt of sulfobenzoic acid, and the ammonia determined by distillation. The benzol-sulfimide was found to be a strong hydrolizing agent, readily inverting cane sugar. With cane sugar the inversion was as complete as by the official method, and upon heating for a long time there was no destruction of sugar. Lactose and dextrose were not affected by the sulfimide, a fact that may be used in the determination of cane sugar in the presence of milk sugar or dextrin, or both.

'The Nature and Function of Soil Solutions,' by F. K. Cameron.

'Permanganate of Potash as a Chemical Antidote,' by V. K. Chesnut. After a critical discussion of the work of La Cerda, Antal, Schlagdenhauffen and Reeb, Moor, Wood and others, who applied dilute solutions of the permanganate as an antidote in cases of human poisoning caused by snake bites, phosphorus, oxalic and hydrocyanic acids, coronillin, morphine and various plant alkaloids, the writer gave the

results of some experiments made with the salt by Dr. E. V. Wilcox and himself in cases of the poisoning of sheep from eating plants. These experiments were made in Montana where hundreds of sheep are killed by certain poisonous plants every year. Preliminary experiments indicate that a one-per-cent. solution of $KMnO_4$, to which one per cent. of the sulfate of aluminum is added, is a wholly satisfactory antidote for poisoning by two of the most poisonous groups of plants of that State, the species of death camas, *Zygadenus*, spp. and the larkspurs, providing, of course, that it be given in the earlier stages of the poisoning. The sulfate of aluminum was added because of the greater oxidizing value which it confers upon the permanganate. The use of the mixed salts in cases of poisoning by other plants is to be further investigated.

L. S. MUNSON,
Secretary.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

THE 533d meeting was held March 30, 1901. Mr. J. B. Baylor read a paper on the 'Magnetic Survey of North Carolina,' which had been carried on jointly by the State and the U. S. Coast and Geodetic Survey. The total cost was stated to have been $16.70 per county, including the establishment at each county seat of a meridian line. Charts of isogonic lines showed many local irregularities, and that the declination had changed several degrees within one hundred and fifty years.

Mr. J. E. Watkins, of the National Museum, gave a half-hour paper on 'A Century of Land Transportation by Steam,' narrating the development of rails, wheels and locomotives, with especial reference to early American practice.

An interesting sketch of Titian R. Peale, one of the founders of the Society, was then read by Mr. A. C. Peale. Mr. Peale was born in 1799 and died in Philadelphia, in 1885. He was assistant naturalist with Long's expedition in 1819, and naturalist to the Wilkes' expedition about 1840; he drew the illustrations for many works on natural history, and for twenty-five years was an examiner in the U. S. Patent Office.

C. K. WEAD,
Secretary.

THE 534th meeting was held April 13, 1901. The first paper upon the program was by Mr. Edwin Smith, on the 'International Goedetic Association Latitude Service.' It consisted of a short general statement of the history of the development of our knowledge of the variation of latitude up to 1898, of the plan of observations devised by the International Geodetic Association in 1898, and of the very satisfactory progress made in carrying out this program at six stations nearly upon the thirty-ninth parallel. Lantern slides were exhibited showing the distribution of the stations in longitude, various curves illustrating the latitude variation, a graphical representation of the program of observation, and the instrument and observatory at Gaithersburg, Md.

Mr. Artemas Martin read a paper on the 'Properties of Rational Plane Triangles.'

JOHN F. HAYFORD,
Secretary.

ANTHROPOLOGICAL SOCIETY OF WASHINGTON.

THE 315th regular meeting of the Anthropological Society was held March 26th.

Mr. William Palmer demonstrated the method of making a life-mask, occupying only fifteen minutes in the operation, and without the use of quills placed in the nostrils.

Dr. I. Casanowicz exhibited Babylonian, Assyrian and Persian seals and four magic bowls from Hilleh, the bowls having inscriptions on the inside in early Aramaic and Syriac character. They are in a fine state of preservation, and the inscriptions consist of formulas for exorcism, but so far there is no clue to the method of their use. The seals shown were lately acquired by the National Museum, and among them are some of the finest examples of ancient cutting.

President W. H. Holmes exhibited several fine obsidian knives from California. One of the blades was 20½ inches long and 5 inches wide, and with it was shown a mass of solid obsidian of the size from which such an implement could have been made. The work of manufacture must have been attended by enormous difficulties. Mr. Holmes explained briefly the process of manufacture of these remarkable specimens of stone-working.

The first stated paper was by Dr. W. W. Johnston on 'The Ill-health of Charles Darwin,' its nature, cause and its relation to his work. Dr. Johnston presented the results of an extended research into the life of Darwin, showing that up to the age of twenty-seven the philosopher was strong and vigorous; then followed thirty-six years of suffering, and eleven years of improvement to the date of his death. Dr. Johnston stated that the visible beginning of Darwin's intellectual life was during the voyage of the *Beagle.* These five years were characterized by constant strain of overwork, which was continued for several years after the voyage, though his nervous system was exhausted. The break-down of Darwin necessitated a strict regimen, the good results of which appeared in the last decade of his life. Dr. Johnston diagnoses the case as one of neurasthenia brought on by overwork, the symptoms appearing on the voyage of the *Beagle.* The prolongation of Darwin's life was due to the regimen adopted and the unremitting care given him by the members of his family. The paper was discussed by Dr. Frank Baker and Dr. Theo. N. Gill.

Dr. George M. Kober read a paper entitled 'The Progress of Charity Reform in the District of Columbia since 1896.' Dr. Kober's paper was more than locally interesting in showing what may be done by the application of rational methods to the charity problem. These are personal inspection as to the needs of applicants, stimulation to self-help by aid in securing employment, and the encouragement of small savings during times of production, to be drawn upon in times of stress. The progress noted under this system since 1896 is remarkable. Dr. Kober presented statistics showing a great diminution in applicants for aid, a heavy reduction of the expense of conducting the work, and a large increase in the number of those depositing savings.

WALTER HOUGH.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

At the meeting of the Academy of Science of St. Louis on April 1, 1901, thirty-three persons present, a memorial notice of the late Judge Nathaniel Holmes, a charter member of the Academy, was presented by a committee composed of Professor Nipher, Dr. Sander and Dr. Baumgarten.

Mr. John S. Thurman delivered an address on the many industrial uses now made of compressed air, illustrating his remarks by apparatus in operation, including electric motor air compressor, compressed air auger, drill, disinfecting atomizer, sculptors' and stone-cutters' tools, carpet renovators, etc., and a set of lantern slides showing the practical uses made of these and other implements and machines operated by means of compressed air.

Dr. Theodore Kodis exhibited, under the microscope, slides illustrating a new method of staining brain tissue, whereby, in four or five days, it has proved possible to prepare single or double stained preparations containing nerve cells with the dendrides of the latter brought out by a direct stain, instead of being differentiated merely as amorphous silhouettes, as is the case with the much slower Golgi process commonly employed. It was stated that the material is treated before sectioning, for about twenty-four hours, with cyanide of mercury, followed for approximately the same length of time by a formaldehyde solution, after which sections are cut, stained with phosphomolybdate hæmatoxylin and, if desired, a contrasting stain, such as one of the aniline greens, and mounted in the usual way.

WILLIAM TRELEASE,
Recording Secretary.

THE ELISHA MITCHELL SCIENTIFIC SOCIETY, UNIVERSITY OF NORTH CAROLINA.

The 134th meeting of the club was held on April 9th, when the following papers were read:

'First Aid to the Injured in the United States Army': Professor C. S. Mangum.

'The Work of the Commission for the Examination of the United States Mint': President F. P. Venable.

CHAS. BASKERVILLE,
Secretary.

DISCUSSION AND CORRESPONDENCE.

OIL IN TEXAS.

To the Editor of Science:—You doubtless have remarked that in various commercial journals the oil which flows in such

quantities from the Lucas and other wells near Beaumont, Texas, is said to come from Tertiary sands. As Geologist to the State of Louisiana I crossed over into Texas to examine the wells and their surroundings. I found them located on a slight rise of ground extending in a east-westerly direction. The length of this slight elevation is perhaps ¾ mile, width ½ mile, and height about 25 feet above the flat surrounding prairie region. Few or no mounds were observed immediately around this rise, but upon the same they are small, but great in numbers. At the time of my visit there was but one well flowing, others not having reached the oil-bearing bed. Strict secrecy was kept as to the depth of the well. I was requested to pick up no specimens and to leave the premises. However, the shells surreptitiously obtained were sufficient to convince me that the Tertiaries were not completely penetrated; and the 'cap rock of the oil' shown in Beaumont seemed to be of decidedly Cretaceous appearance. The conclusion to be drawn was therefore that the well penetrated possibly a thousand feet of rather recent or newer Tertiary strata and then came upon some portion of a Cretaceous anticlinal fold or ridge. A statement to this effect was given to the New Orleans *Picayune*, March 27, 1901 (which see). To-day we notice that the same paper published, on April 10, a log of the Higgins well. We notice in complete corroboration of our theory the following items:

"1030 ft.—Oil-bearing sand, pebbles and sulphur.

"1040 ft.—Sulphur rock; solid.

"1045 ft.—Oil."

The well is therefore, as supposed, *i. e.*, a repetition of the 'Sulphur Mine' condition of Southwestern Louisiana, buried about twice as deeply beneath the surface by recent formations.

Through the kindness of Mr. Pattillo Higgins, a large holder in this new oil territory, we are assured of a set of samples and shells obtained from the various depths of his well. This will enable us to see just how much of the Tertiaries are missing between the Quaternary and Cretaceous oil beds.

G. D. HARRIS.

DISCLAIMER NO. 2.

IT is necessary that the undersigned inform the general public that the use made of their names by the 'American College of Sciences,' doing business at Philadelphia, in advertising an 'advanced course in personal magnetism, hypnotism and suggestion by seven distinguished specialists,' is wholly unauthorized and unwarranted. The public is warned against the trick of being thus led to believe that we concur in the statements made in this advertising scheme concerning the scientific facts and the practical uses of hypnotic influences. The undersigned believe that the practice of hypnotism should be restricted to a most guarded application.

Our names and the 'courses' advertised in this 'advanced course' are derived from articles which each of the undersigned was requested, individually, by the 'New York State Publishing Company,' of Rochester, N. Y., to prepare for a scientific exposition of the facts and principles of hypnotism and allied phenomena. The compilation appeared from the press late in 1900. Had the undersigned had any intimation whatsoever that this second and unauthorized use of the articles was to be made, viz., as a part of a course of instruction in the general subject, they would have absolutely refused to contribute to the compilation in the first instance. The responsibility of each of the undersigned goes no farther than the contents of the original article he contributed to the compilation.

The disclaimer is to be taken in accord with the one appearing in SCIENCE, November 30, 1900, p. 850, and in *The Psychological Review*, January, 1901, p. 63. The names here undersigned appear in an advertising sheet circulated by the 'College' which omits the names appearing under the first disclaimer.

SHORTER ARTICLES.

NOTES ON THE DEVELOPMENT OF THE POLLEN TUBE AND FERTILIZATION IN SOME SPECIES OF PINES.

DURING the past three years, I have devoted considerable time, under the direction of Professor George F. Atkinson, to a study of fertilization and related phenomena in certain species of pines. A preliminary paper was read before the Botanical Society of America at its Boston meeting, August, 1898. In June, 1900, a more complete report of the work was given in two papers, one of which was presented before the society named above at its meeting in New York City, and the other before the American Association for the Advancement of Science, which Association also met in New York City.

It has been found that the generative cell appears, as a rule, during the first summer rather than shortly before fertilization, as described by other investigators. This cell does not divide while in its place within the pollen grain, as stated by previous writers, but passes into the pollen tube before the sperm cells are formed. In the division of the generative nucleus, the spindle is monopolar in origin; it arises some distance below the nucleus in a prominent cytoplasmic condensation. From this denser area the protoplasm extends in a radial manner towards the periphery of the cell. The sperm nuclei are never separated by a cell wall, but remain surrounded by a common mass of cytoplasm. The two nuclei are of unequal size from the first, and the larger one is always in advance of the smaller one, as regards the apex of the pollen tube.

Just prior to fertilization a cavity is formed in the upper part of the egg cytoplasm. It is believed that this cavity represents the final act of the egg in its preparation for the reception of the sperm cell and other contents of the pollen tube. There is no evidence that it results from the presence, within the egg, of the elements from the pollen tube, as reported by certain writers. The sperm nucleus does not increase in size after its entrance into the egg, but remains much smaller than the nucleus of oösphere. The sexual nuclei come to lie side by side but do not fuse; both nuclei can still be identified, even after the membrane of each has entirely disappeared. Two chromatic groups are clearly distinguished up to the nuclear plate stage.

In the division of the two segmentation nuclei, the chromatin of each nucleus forms two distinct spirems, which doubtless represent the separated-out paternal and maternal chromatic substance. At the time of this second division within the oösphere, the smaller sperm nucleus, which still lies in the upper part of the egg, frequently gives rise to a mitotic figure of more or less definiteness.

Only a few of the results which have been obtained are noted above. Papers giving the details of this research, with discussion and plates, have been sent to the publishers and will appear shortly.

BOTANICAL DEPT., CORNELL UNIVERSITY.

NOTES ON ENTOMOLOGY.

WITH the December (1900) number the *Entomologische Nachrichten*, long edited by Dr. F. Karsch, closes its career. In its place will be issued a monthly index of entomological publications, called *Entomologische Litteraturblätter.*

M. AUG. LAMEERE, in a recent proposed classification * of the Coleoptera, divides the order, according to the variation of the median vein of the hind wings, into three suborders; viz., Cantharidiformes, Staphyliniformes and Carabiformes; the last is equal to the Caraboidea of Ganglebauer. The second suborder equals the Staphylinoidea of that author with the important addition of the Pulicidæ.

M. Lameere's idea that the fleas are Coleopterous insects is certainly novel, and is based on a supposed affinity with *Platypsyllus*, the well-known parasite of the beaver. The Cantharidiformes contains all the other families.

M. Lameere makes a list of the characters that (according to him) must have been possessed by the ancestor of Coleoptera; these characters indicate a Neuropterous insect of the group of Plannipennia. The most primitive Coleoptera he finds in the family Lymexylidæ.

* Notes pour la classification des Coléoptères. *Ann. Soc. Ent. Belg.*, 1900, pp. 355–357.

In this family two genera are mentioned which possess prominent ancestral characters: *Atractocerus*, with eight visible ventral segments, and *Hylecœtes*, with a rudimentary median ocellus.

Professor I. Bolivar describes * and figures a remarkable Coleopterous larva belonging to the family Lampyridæ which he received from the Philippines. At a casual glance the figure looks much like that of some fossil trilobite. The thorax is extremely large and broad, the head apparently sunk in the prothorax; the abdominal segments are small and laterally produced. M. J. Bourgeois, who has examined the figure thinks that it may belong to the genus *Broxylus*, a genus close to our *Calopteron*.

A. Skorikow in an article on some Collembola from Spitzbergen † gives a résumé of the known distribution of Collembola on Arctic islands. Of the thirty-four species only fourteen have been recorded from more than one island. Six species are common to four different islands, five of these being well-known European forms. He also tabulates the percentage of species in the various families and compares it to the Russian Collembola. This shows that in the Arctic regions the Aphoruridæ, Poduridæ and Isotomini are the predominant types, while in Russia the Entomobryini and Smynthuridæ are the predominant forms.

Mr. F. O. P. Cambridge has begun ‡ a revision of the genera of spiders with reference to their type species. He differs considerably from both Simon and Thorell, who have previously investigated this subject. He makes several important changes in this part. The genus *Drassus* is held not to be a synonym of *Gnaphosa*; *Micromata* becomes transferred to the Clubionidæ, with *M. accentuata* Walck. as type; and *Salticus* has for its type *S. scenicus*, so that *Epiblemum* falls to the synonymy. It is doubtful, however, if Mr. Cambridge's work will lead to greater uniformity in the use of genera of spiders, as so much depends on the rules used in type-fixation. Few of the ancient authors had the slightest idea of a genotype, so that every attempt to read this modern idea in their writings will be largely influenced by opinion. In fact there is less uniformity in the use of genera of spiders than there was ten years ago.

* Dos formas larvarias de lampiridos. *Act. Soc. Española de Historia Natural*, Vol. XXVIII., 1899, p. 130–133.

† Annuaire du Musée Zoologique Acad. Imp. St. Petersburg, Vol. V. (1900), p. 190–209.

‡ *Ann. Mag. Nat. Hist.*, 1901, Jan., pp. 51–65.

S. Prowazek has studied * the development of a Collembolan, *Isotoma grisea*, and finds, among other interesting matters, that the antennæ are primitively post-oral, and attain their pre-oral position at a later stage.

MM. J. Danysz and K. Wize have published a little brochure † on the use of fungous diseases against *Cleonus punctiventris*, a weevil injurious to beets and mangel-wurzels in Central Europe. The value of this method had previously been shown by several Russian experimenters, notably by Professor Krassilstchik, of the University of Odessa. The work of the French writers has been principally on methods of inoculating the soil. They found that where the beet is cultivated by rotation every four or six years the fungus was apt to die out. Therefore, they have devised methods for inoculating the beet fields anew each year.

Nathan Banks.

WORKING OF PATENTS ACTS.

Probably no single influence has had more to do with the advancement of the industrial interests of the United States and with the resultant prosperity of the nation than the patent-acts. They were fundamental elements of primary legislation on the organization of the Government, and Hamilton and other of those early statesmen to whom so much is due initiated a patent system as a first and most effective instrument in the development of manufactures in a country previously deprived of those industries through the repressive legislation of the mother country. The patent system of the United States became a model for the world and, very slowly but none the less steadily, other nations, one by one, took up its most distinctive methods. The United States promptly

* *Arbeit Zool. Inst. Wien*, XII. (1900), pp. 335–370.

† De l'utilization des Muscardines dans la lutte avec le *Cleonus punctiventris*. Paris, 1901.

secured a lead, as great in its field as has become, meantime, that of Germany in industrial education. During late years, the patent system of Great Britain, formerly exceedingly crude, costly to the inventor and the nation, and in all ways unsatisfactory to those who were unselfishly and honestly interested in the advancement of British trade, has been greatly modernized and liberalized; but it has not, even yet, been made fairly comparable with that of the United States.

An important commission, appointed by the Board of Trade and composed of some of the ablest experts and best known men in the kingdom, has just reported upon its operation and it is perhaps possible to deduce from this report conclusions that may be useful in promoting the still further improvement of our own system, of late years reduced rather than improved in its efficiency by legislation and by official interpretations of doubtful provisions of law. After examining into the operation of the British patent laws and receiving the testimony of officials of the patent office, of referees, litigants, users of patented articles, patent agents and experts, the commission reported.

It was found that, of patents issued, only 57.6 per cent. were actually novel and unanticipated by previous invention. Nearly 7 per cent. had been fully anticipated in all details; 35 per cent. had been partially anticipated; a few were claims on old devices and others described no method of manufacture. Forty-two per cent. had thus been anticipated, in whole or in part.

The commission states its opinion that the granting of invalid patents is thus a very serious evil and one which should be at once abolished. A method of examination like that of the U. S. Patent Office is recommended, and a scrupulous system of detection and elimination of anticipated claims. It recommends, however, a curious limitation: That "the publication of an invention in specifications of letters patent granted in the United Kingdom dated fifty years or more previous to the date of the application, or in a provisional application, of any date, of the kind before mentioned, shall not in itself be deemed an anticipation of the invention."

It is recommended that time, not to exceed two *months* (two *years* time is given in the United States Patent Office) should be allowed for amendment of a claim, and that a system of appeal, very like that long in operation in the United States, be allowed in case of rejection. This provision, restricting amendment to a period of two months, if it had been adhered to in the United States, would have prevented the litigation now in progress over the Berliner and other patents in this country, and would have saved a vast amount of expense to the litigants and insured a larger employment of inventions in improvement of existing practice and would have saved enormous injury to patentees and to the nation.

This British commission also considers the matter of compulsory licenses. It often happens, in that country as in this, that valuable patents are purchased by wealthy and powerful interests and simply held, unused, to prevent their competition with the holders and to evade that serious difficulty often met with in the compulsory replacement of existing and fairly satisfactory apparatus by the improved device. Every great corporation and many smaller organizations hold patents thus concealed and out of use, until their own special interests make it desirable to put them into use; and the public is thus defrauded of all that advantage, meantime, which is its proper compensation for the establishment and maintenance of a patent system. The British patent laws have, for nearly twenty years, provided, as have *not* those of the United States, against this abuse. It is made the duty of the proper officials to grant an order compelling the holder of the patent to grant licenses on terms to be adjudged fair and equitable by the proper government officials. This provision has been subject to some criticism in its details, and the commission advises its amendment and improvement; adhering, however, to the underlying principle that the public should not lose its rights or the advantage assumed to be gained by it when providing the legal forms of a patent system and of protection to the inventor. It is recommended that the 'High Court' shall receive and consider complaints reciting the facts, if they so prove, that the applicant is in-

terested in the invention, that the reasonable requirements of the public have not been satisfied, by reason of the refusal or neglect of the patentee to work, or to grant licenses to work, the patent, and that the court, if the assertions of the claimant appear to be justified by the facts, shall make an order conferring a license upon the applicant on terms found by the court itself to be just and reasonable.

Reciprocity in patent matters is advised as between Great Britain and other countries prepared to offer similar facilities and protection for the foreign patentee. It would be an excellent reform could a real international reciprocity, based on the best practice of the United States, be arranged to include Germany; which country has illustrated some very objectionable and inequitable patent law methods.

Should the recommendations of the commission be accepted and the British Office be reconstructed as proposed, it will provide as practically satisfactory a system of protection as does that of the United States; changing thus from one of the most useless to one of the best of patent systems of the time. It will be interesting to note whether Great Britain, after all, will ultimately provide a more equitable system in regard to purposely delayed issues and unworked patents—the two main defects and abuses of the existing law of the United States—than our 'pioneer' code now offers. It will be most discreditable if our committees of Congress and our Commissioners of Patents do not initiate, and Congress perfect, remedies for these two radical and inexcusable defects in our own patent law.

R. H. THURSTON.

A MINERAL SURVEY IN TEXAS.

THE Legislature of the State of Texas has recently passed an act (House Bill 135), approved by the Governor, March 28, 1901, providing for "a mineral survey of the lands belonging to the public schools, university and asylum, or of the State, and to make appropriation therefor, and to provide a penalty for unlawfully disclosing information obtained by such survey; and to loan and authorize the removal to the University of the geological and scientific equipments, collections, specimens and publications now in charge of the Commissioner of Agriculture, Insurance, Statistics and History; and also declaring an emergency."

By Section 1 the "Board of Regents of the University of Texas are authorized and directed, as soon as practicable, to have made a mineral survey of all lands belonging to the public schools, university, asylums, or of the State."

Section 2 requires that "said Board shall employ for that purpose persons skilled, who have had at least five years' experience, in the science of mineralogy, geology and chemistry, who shall conduct said survey. * * *"

Section 3 relates to the publication annually 'for free distribution among the people of the State [of] all practical information collected in the prosecution of said survey as it progresses.' It provides, as a penalty, a fine 'not exceeding one thousand dollars or two years in jail' for divulging information concerning the public school, university, asylum or State lands in advance of publication.

In Section 4 provision is made 'for assays, analyses and other scientific examinations of specimens of mineral substances found in the State, and for the collection and distribution of statistics relating to the mineral production of the State. * * *' For the assays, etc., a 'uniform and reasonable charge shall be fixed,' except at the request of the Governor or Commissioner of the General Land Office the examination of specimens found upon any of the public lands shall be made free of charge.

Section 5 provides for instruction in the University of Texas 'in practical economic and field geology and mineralogy,' and for the distribution of duplicate specimens to the A. and M. College.

Section 6 authorizes the removal of the specimens, books, and equipment (brought together by the Dumble Survey) now in charge of the Commissioner of Agriculture, Insurance, Statistics and History, to the University. These materials are 'loaned to said board, until such time as the State may desire to otherwise use them.'

Section 7 reads as follows: "For the purpose of carrying out the provisions of this Act, the sum of ten thousand dollars per annum for two years, or so much thereof as may be necessary,

is hereby appropriated out of the general revenue of the State; provided that said mineral survey of the State shall be completed within two years."

Section 8 repeals all laws in conflict with the Act, and Section 9 declares an emergency.

It is the intention of the Board of Regents to immediately institute the work of the survey, which will probably be under the direction of Dr. William B. Phillips, who is in charge of economic and field geology in the University.

FREDERIC W. SIMONDS.

SCHOOL OF GEOLOGY,
UNIVERSITY OF TEXAS, April 6, 1901.

PROPOSED SURVEY OF THE ANTIQUITIES OF MICHIGAN.

THE following bill has been introduced in the Michigan Legislature, was reported favorably by the Committee on State Affairs, and is at present referred to the Committee on Ways and Means. An amendment limiting the survey to two years has been made.

The people of the State of Michigan enact:

SECTION 1. That a survey of the antiquities of Michigan be, and the same is hereby established.

SECTION 2. That the survey shall be in charge of a commission comprising the Governor of the State *ex-officio*, the President of the University of Michigan, the President of the Michigan Academy of Sciences, the President of the Pioneer and Historical Society and the President of the Detroit Archeological Society; this commission to serve without compensation, but to be reimbursed for their actual and necessary expenses.

The commission shall have the power to employ an archeologist and one or more assistants and to make such incidental expenditures as the nature of the work may require. The accounts for salaries and other expenses provided herein shall be paid upon the warrant of the Auditor-General monthly, upon the approval of the Governor. At the end of each fiscal year the commission shall cause to be made an annual report, the copy for which, as soon as completed, shall be forwarded to the clerk of the Board of State Auditors for publication by the State printer, the expense of such publication to be paid from the general fund of the State upon the allowance of the Board of State Auditors.

SECTION 3. For the purpose of carrying out the provisions of this act, exclusive of the cost of publishing the annual reports, there is hereby appropriated from the general fund of the State for the fiscal year ending June thirty, nineteen hundred and two, and each fiscal year thereafter, the sum of two thousand five hundred dollars.

THE DAVENPORT ACADEMY OF SCIENCE.

THE annual meeting of the Academy was held on January 25th in Davenport, Iowa. The reports for the year were most encouraging.

We learn from Mrs. Mary L. D. Putnam, President of the Academy, that the Academy has purchased the corner property adjoining its present building and converted the church into a most attractive lecture hall; the high basement makes a fine room to relieve the former crowded museum. The two buildings are connected by a spacious and well-lighted passageway which may also be utilized for museum purposes.

The scientific library of 10,800 bound volumes has been completely catalogued exclusive of a large collection of pamphlets. The library has been acquired by the exchange of the proceedings of the Academy with home and foreign scientific societies.

The Academy is one of the oldest of the scientific institutions in the West, and on December 14, 1900, celebrated the 33d anniversary of its founding by the dedication of Science Hall. President MacLean and Professor Nutting of the State University of Iowa made addresses, and Professor Starr, of the University of Chicago, gave a lecture 'Among Mexican Indians.'

It is planned to give free scientific lectures from time to time in this hall.

With its large museum, especially rich in archeology and enlarged by the recent gift of the rare Griswold College Collection, including 2,000 scientific books, and with its valuable property, the Academy is on a permanent basis, needing only an addition to its general endowment fund.

The publication is assured by the Putnam Memorial Fund. The income of this fund of

$10,000 has enabled the Academy this last year to bring out Volume VII., containing 316 pages and seventeen full-page plates.

PROPOSED JOURNAL FOR THE STATISTICAL STUDY OF BIOLOGICAL PROBLEMS.

IT is proposed to established a *Journal of Biological Statistics* which may serve as a means not only of collecting under one title biological data of a kind not systematically collected or published in any other periodical, but also of spreading a knowledge of such statistical theory as may be requisite for their scientific treatment. The following remarks are offered in justification of this proposal:

A very few years ago, all those problems which depend for their solution on a study of the differences between individual members of a race or species were neglected by most biologists. The complexity of organic structure is so great, and the number of distinguishable forms so enormous, that morphologists were obliged to simplify their conceptions by constructing for every species an ideal type, to which the individuals composing it conform with more or less exactness, and to neglect those deviations from the type which actually occur. Such simplificatian was not only justifiable, but absolutely necessary for many purposes; it has rendered enormous service to biology in the past, it does so still and will continue to do so; nevertheless, there are many problems which can not be dealt with by its aid.

The starting point of Darwin's theory of evolution is precisely the existence of those differences between individual members of a race or species which morphologists for the most part rightly neglect. The first condition necessary, in order that any process of natural selection may occur among a race or species, is the existence of differences among its members; and the first step in an enquiry into the possible effect of a selective process upon any character of a race must be an estimate of the frequency with which individuals, exhibiting any degree of abnormality in respect to that character, occur. The unit, with which such an enquiry must deal, is not an individual but a race, or a statistically respresentative sample of a race; the result must take the form of a numerical statement, showing the relative frequency with which the various kinds of individuals composing the race occur.

As it is with the fundamental phenomenon of variation, so it is with heredity and with selection. The statements that certain characters are selectively eliminated from a race can only be demonstrated by showing statistically that the individuals which exhibit that character die earlier, or produce fewer offspring, than their fellows: while the phenomena of inheritance are only by slow degrees being rendered capable of expression in an intelligible form as numerical statements of the relation between parent and offspring, based upon statistical examination of large series of cases, are gradually accumulated.

These, and many other problems, involve the collection of statistical data on a large scale. That such data may be rendered intelligible to the mind, it is necessary to find some way of expressing them by a formula, the meaning of which can be readily understood, while its simplicity makes it easy to remember. The recent development of statistical theory, dealing with biological data on the lines suggested by Mr. Francis Galton, has rendered it possible to deal with statistical data of very various kinds in a simple and intelligible way, and the results already achieved permit the hope that simple formulæ, capable of still wider application, may soon be found.

The number of biologists interested in these questions, and willing to undertake laborious statistical enquiries, is already considerable, and is increasing. It seems, therefore, that a useful purpose would be served by a journal especially devoted to the publication of statistical data, and of papers dealing with statistical theory. Many persons are deterred from the collection of such data, by the difficulty of finding such a means of publishing their results as this journal would afford, and those results which are published frequently lose much of their value because the data on which they are based are withheld, or because they are isolated in publications largely devoted to other forms of investigation.

It is suggested that '*Biometrika*, a Journal for

the Statistical Study of the Problems of Evolution,' should be published, in the first instance, quarterly, four numbers forming a volume. It is hoped that it will include (*a*) memoirs on variation, inheritance and selection in animals and plants, based upon the examination of statistically large numbers of specimens (this will of course include statistical investigations in anthropometry); (*b*) those developments of statistical theory which are applicable to biological problems; and (*c*) abstracts of memoirs, dealing with these subjects, which are published elsewhere. It is proposed to include memoirs written in English, German, French or Italian.

The expense of such a journal would be at first considerable, and it cannot be undertaken without some promise of support. Those willing to assist in supporting such a journal are requested to write either to Professor Karl Pearson, F.R.S., University College, London, or Professor W. F. R. Weldon, F.R.S., Merton Lea, Oxford, agreeing to purchase the first volume of *Biometrika* at the price of 30 shillings.

RESIGNATIONS FROM THE SCHOOL OF PEDAGOGY NEW YORK UNIVERSITY.

We published last week a letter from Professors Weir, Buchner and Judd announcing their resignation from the School of Pedagogy, New York University. In view of comments made by Chancellor MacCracken, we have been asked to publish the following statement signed by Professors Weir, Buchner and Judd:

There have been long-continued disagreements within the Faculty of Pedagogy on points of general policy. The advice of the Chancellor on these matters could not be obtained, as the Chancellor has declined to attend Faculty meetings for more than a year, and has not attended more than two or three times during the last three years. Appeals made to the authorities of the University on matters of general policy were not taken up for definite consideration until in February of this year when two long hearings were held before a Council Committee, consisting of Chancellor H. M. MacCracken, Dr. George Alexander, Chairman; Willis Fletcher Johnson, Secretary; Henry Van Schaick, and a number of ladies of the woman's advisory committee, including Mrs. Henry Draper, Miss Helen M. Gould, and Mrs. Eugene Smith. These hearings dealt with questions of administration and curriculum.

After these two hearings and after a meeting of the council of the University on March 4th, the Chancellor announced to the members of the faculty that he had accepted the resignation of the dean of the School of Pedagogy from the deanship. The Chancellor also sent word to one of the members of the faculty that the general theory of reconstruction would make it necessary to vacate his chair in order to make room for a new Dean. The member who was thus to be superseded made an effort to find out the grounds of this theory of reconstruction. He was informed that no criticisms of his academic work and conduct had been communicated to the Chancellor. The only semblance of a reason for the theory appeared in certain vague and indefinite impressions entertained by some of the members of the woman's advisory committee. The other two members of the faculty made an effort to find out the grounds of this theory of reconstruction. They were unable to find reasons other than those already stated, excepting the additional fact that the Chancellor had not in the beginning favored the appointment of this professor. They accordingly entered a vigorous protest, both in person and by correspondence, to the Chancellor and Dr. George Alexander, against what they regarded as an unwarranted and unjust line of action.

The committee of the council, including the members of the woman's advisory committee, then held on April 4th a meeting, and passed a resolution to recommend to the Council that the chairs of all professors of the Faculty of Pedagogy, not vacated by resignation, be declared vacant by the council at its May meeting. It should be noted that this resolution applies not merely to the three professors who have resigned, but to all professors in the School of Pedagogy.

On learning of this action on the part of the Council Committee, the members of the faculty made an effort to get into correspondence with the Chancellor and secure some statement of the grounds of this latest action. The Chancellor withheld the information requested; where-

upon, Professors Weir, Buchner, and Judd resigned from the University. The following is a copy of the resignation sent by each of the professors to the Chancellor:

April 12th.

To the Chancellor of New York University:

Because of long-continued dissatisfaction with the administration of the School of Pedagogy, and because I have learned that the repeated efforts of certain members of the faculty to improve this administration, while they have met with a sufficient degree of offical approval to mark these efforts as thoroughly justifiable, have, notwithstanding, resulted in a resolution on the part of a Committee of the University Council to recommend that the chairs of all Professors of the School of Pedagogy be vacated at the May meeting of the Council, I therefore resign my professorship in the University, this resignation to take effect at the close of this university year.

I respectfully request that an official statement of the fact, which has been at different times informally stated, that my academic work and conduct as a professor in the University have been satisfactory, be sent to me at once.

A MEETING of students and alumni of the School of Pedagogy was held in the University Building, Washington Square, on April 20th, and the following resolution was passed:

To the Council of the New York University:

We, the former and present students of the School of Pedagogy of New York University, having learned through the public press of the resignations of Professors Weir, Buchner and Judd from the Faculty of the School of Pedagogy:

Hereby beg leave to express our firm belief that the loss of these professors from the Faculty will greatly weaken public confidence in the institution, and will undoubtedly impair its usefulness in the future. These gentlemen are everywhere recognized as thorough scholars, inspiring instructors, and men of sound judgment and impressive personality.

We beg leave, therefore, to express our further conviction that the University will do itself and the educational public of this city a service by securing, if possible, a withdrawal of these resignations.

SCIENTIFIC NOTES AND NEWS.

MR. ALEXANDER AGASSIZ, of Cambridge, Mass., has been elected president of the National Academy of Sciences. The further transactions of the Academy are recorded in a special article published above.

PROFESSOR G. L. GOODALE, of Harvard University, has been appointed delegate from the National Academy of Sciences to the International Association of Academies meeting in Paris.

PROFESSOR E. B. WILSON, of Columbia University, has been invited to deliver the annual address before the Medical School of Yale University.

PRESIDENT ELIOT, of Harvard University, is expected to return to Cambridge this week. He has been for the past three months in Bermuda and the West Indies.

WE learn from the *Botanical Gazette* that a handsome silver loving cup was presented by a number of teachers to Mr. Thomas Meehan, the veteran horticulturist and botanist of Philadelphia, on the occasion of his seventy-fifth birthday.

DR. JAMES E. TALMAGE, professor of geology in the University of Utah, has been elected a life associate in the Philosophical Society of Great Britain, otherwise known as the Victoria Institute, and also a corresponding member of the Royal Scottish Geographical Society.

MR. L. DE NICÉVILLE has been appointed entomologist in the Indian Museum, Calcutta.

WE learn from *Nature* that Professor Eugen Warming and Dr. Victor Madsen have been appointed to the Danish Geological Survey, and that Dr. H. Topsöe has retired from the Survey.

THE Adams prize of Cambridge University for the present year has been awarded to Mr. H. M. MacDonald, of Clare College, for a paper on 'Electric Waves.'

MR. C. E. BORCHGREVINK, the Antarctic explorer, has been created a Knight of the Order of St. Olaf by King Oscar of Sweden and Norway.

DR. ROBERT E. MORITZ, of the University of Nebraska, has received leave of absence for next year which he will spend in study in Germany.

PROFESSOR WATASÉ informs us that at the meeting of the Zoological Society of Tokio, held at the Zoological Institute of the University of Tokio, March 15, 1901, Professor Bashford Dean, of Columbia University, gave an account of his trip to the Philippines. Among others,

he gave a very graphic account of the habits of *Nautilus* which he had observed during his stay at Negros.

Professor Frederick W. Starr, of the University of Chicago, has returned from a four months' expedition among the Mexican Indians. He has secured valuable busts, photographs and collections.

The section of vertebrate paleontology of the Carnegie Museum will have four field parties engaged during the coming summer in exploring the fossil-bearing horizons of the West. The work will be under the general direction of Mr. J. B. Hatcher, the Museum's curator of vertebrate paleontology. One party will operate near Cañon City, Colorado, where during the past winter a valuable deposit of Dinosaur bones has been unearthed by Mr. W. H. Utterback. A second party will be in charge of Mr. C. W. Gilmore, and will continue the work that has been so successful during the past two seasons in southern Wyoming. A third party will be in charge of Mr. O. A. Peterson, and will explore the Tertiary deposits of western Nebraska, while the fourth party will devote its attention to the Cretaceous and Tertiary deposits of southern Montana. Important results are expected from the various field parties.

Dr. Henry C. Cowles will conduct an expedition of students from the botanical department of the University of Chicago to the mountains of northwestern Montana and northern Idaho during August and a part of September. The purpose of this trip will be an ecological study of the various mountain conditions.

S. M. Tracy, of Biloxi, Miss., has chartered a schooner for the summer, and will spend the next six months in a botanical exploration of the islands along the coast of the Gulf of Mexico. May, June, September and October will be spent on the south Florida coast, and July and August on the Texas coast.

Professor Engler, director of the Botanical Garden at Berlin, is about to visit the Canary Islands, in order to study their flora; at the same time the botanist, Dr. Josef Bornmüller, will also make an expedition.

The funeral of the late Professor Henry A. Rowland took place during the recent meeting of the National Academy of Sciences, and Dr. S. P. Langley, Secretary of the Smithsonian Institution, and Dr. T. C. Mendenhall, President of the Worcester Polytechnic Institute, were appointed a committee to represent the Academy.

A portrait of the late Dr. William Pepper was presented to the American Philosophical Society on April 12th by a number of members of the Society. An address was made on the occasion by Dr. Horace Howard Furnace.

Dr. Frederick J. Brockway, assistant demonstrator in anatomy in the College of Physicians and Surgeons, Columbia University, died of meningitis at Brattleboro, Vt., on April 21st. He was born in 1860 and took his A.B. at Yale and his M.D. from the College of Physicians and Surgeons.

We regret also to record the death of Richard P. Rothwell, since 1873 editor of the *Engineering and Mining Journal*. He was born in Ontario, Can., in 1836, and studied at Trinity College, Toronto, the Rensselaer Polytechnic Institute and the Paris School of Mines. Mr. Rothwell made numerous inventions and had a large practice as consulting mining engineer. He was president of the American Institute of Civil Engineers in 1872, and was a member of numerous foreign and American Scientific Societies. In connection with the *Engineering and Mining Journal* he published annually 'The Mineral Industry, its Statistics, Technology and Trade,' and the company of which he was president, The Scientific Publishing Company, issued many books relating to industry and mining. His death, which was due to cancer, occurred on April 17th.

Professor Josef von Fedor, professor of hygiene in the University of Buda Pesth and the author of many works on this science, has died at the age of fifty-seven years.

The death is also announced of Dr. P. Kohlstock, lecturer on tropical hygiene at the University of Berlin, and known for his researches on cholera and other subjects. He died at Tien-Tsin, where he was engaged in research.

A PRESS cablegram from Berlin states that Dr. Menke, leader of a German scientific expedition in the South Sea Islands, has been murdered by natives of Macquarie Islands. Two other members of the expedition were wounded.

THE Legislature has not made an appropriation with which the New York Pathological Institute can pay rent for the laboratory it now occupies, and it will be necessary to remove the fine equipment to Manhattan State Hospital on Ward's Island. Dr. Ira Van Gieson will not be continued as director of the Institute after the first of May.

A CORRESPONDENT in San Francisco informs us that the bill making it a felony to publish that cholera or bubonic plague exists within the State of California, unless the fact has been entered on the minutes of the Board of Health, after having been passed by one branch of the Legislature was dropped. Dr. John J. Kinyoun, federal quarantine officer at San Francisco, to whom we understand the investigation of the plague in that city was due, has been transferred at the request of commercial organizations. The attitude of the San Francisco press towards the investigations of the plague by the federal authorities is shown by the following extract from the *Call* of April 16th.

> Dr. Kinyoun was the worst enemy the State had ever had. His circulation of bubonic plague reports inflicted incalculable injury upon the State in general and San Francisco in particular. The salient fact that a number of deaths in the Chinese quarter during the past twelve months, with Dr. Kinyoun's bubonic nightmare thrown in, was no greater than for any one of the preceding years, could not stay the damage done by Kinyoun's sensational declarations.

IN the London *Times* and in *Nature* we find some information regarding the inaugural meeting of the International Association of Academies which was called to meet in Paris on the 16th inst. The following delegates were expected to be in attendance: Amsterdam, Professor H. G. van de Sande Bakhuysen, president of the physico-mathematical section of the Academy; Professor H. Kern, president of the section of letters; Professor J. de Goeje. Berlin: Professor H. Diels and Professor W. Waldeyer, permanent secretaries of the Prussian Royal Academy of Sciences; Professor R. Helmert; Professor J. H. van't Hoff; Professor T. Mommsen; Professor E. Sachau. Brussels: Lieut.-General de Tilly; Professor P. Fredericq. Budapest: Professor C. Than; Professor I. Goldziher. Christiania, not yet announced. Göttingen: Dr. E. Ehlers and Dr. F. Leo, secretaries of the Society; Professor E. Riecke. Copenhagen: Professor J. L. Heiberg; General G. Zachariæ. Leipzig: Professor W. His; Professor A. Fischer; Professor H. Gelzer. London: Sir Michael Foster and Professor A. W. Rücker, secretaries of the Royal Society; Dr. T. E. Thorpe, foreign secretary of the Society; Sir Norman Lockyer; Sir Archibald Geikie; Professor A. R. Forsyth; Professor E. Ray Lankester; Professor A. Schuster. Munich: Professor W. Dyck; Professor F. Lindemann; Professor K. Krumbacher. Paris, Academy of Inscriptions and Belles Lettres: Count De Lasteyrie, president; MM. P. Berger, vice-president; H. Wallon, permanent secretary; L. Delisle; G. Boissier; Bréal; Barbier De Meynard; Senart; E. Müntz. Academy of Sciences: MM. Fouqué, president; Bouquet de la Grye, vice-president; Berthelot and Darboux, permanent secretaries; Marey; H. Poincaré; Moissan; Lannelongue. Academy of Moral and Political Sciences: Count de Franqueville, president; G. Picot, permanent secretary; Gréard; Glasson; Lachelier; Sorel; Boutroux. St. Petersburg: MM. Famintzin; Backlund: Oldenbourg; Kouliabko. Rome: Professor S. Cannizzaro; Professor A. Mosso; Professor I. Guidi. Stockholm: Professor G. Retzius, president of the Academy of Sciences. Washington: Professor G. L. Goodale. Vienna: Professor Victor von Lang, general secretary of the Academy of Sciences; Professor T. Gomperz; Professor Leopold von Schroeder; Professor J. Karabacek; Professor J. C. Zirecek; Professor A. Rollett; Professor G. Tschermak. The delegates were to be officially welcomed to Paris by the French Government and the Institute of France; and the arrangements for their pleasure included receptions at the Château de Chantilly, bequeathed to the Institute of France by the Duc d'Aumale, at the French Academy and elsewhere, a visit to the Bibliothèque Nationale under the conduct of its

accomplished director, M. Léopold Delisle, and a special representation at the Comèdie Française. On Thursday, the 18th, the Institute of France would give a dinner in honor of the assembly, and on Saturday the delegates were to be entertained at a banquet by the Paris Municipal Council. Regarding the scientific work of the Association, we find less information, but it is said that the Royal Society has on the agenda a proposal relating to the desirability of connecting the measurements of Struve upon the arc of meridian 30° E., with those of Gill on the same meridian in South Africa, and the Paris Academy raises the question of the standardization of the recording instruments used in physiology and increased uniformity in the methods of that science.

The American Metrological Society held its annual meeting at Washington on April 19th with the President, Dr. T. C. Mendenhall, in the chair. Dr. Mendenhall made an address on the recent progress of the metric system here and abroad. Among the other papers was one by Dr. S. W. Stratton, director of the newly established Bureau of Standards, on the plans for the Bureau.

The annual meeting of the Society for the Promotion of Engineering Education will be held at Buffalo, June 29, July 1 and 2, 1901. The sessions will be held in 933 Ellicott Square.

The Buffalo Society of Natural Sciences has announced a series of lectures to be given by Mr. Frederick Houghton of the Buffalo schools beginning April 25th. They are on physical geography and are designed specially for teachers. Each lecture will be followed by an excursion to study the local physical conditions described.

The subject for the Adams Prize at Cambridge University for 1903 is 'The bearing on mathematical physics of recent progress in the theory of the representation of discontinuous quantity by series, with special consideration of the logical limitations of the processes involved,' the value of the prize is about $1,100, and it is open to those who have taken a degree at Cambridge. The subject for the Sedgwick prize, 1903, is 'The Petrology of some Group of British Sedimentary Rocks.'

The Fossati Prize of the Lombard Academy of Sciences and Letters will be awarded in 1902 for an essay on the 'Minute or gross anatomy of the brain.' In 1903 the subject is 'The termination of the cranial nerves in the brain.' The prize is of the value of about $400 and is open only to Italians.

The *American Mathematical Journal* announces that the Naples Academy of Mathematical and Physical Science has awarded its mathematical prize of 100 lire for 1899 to Dr. G. Torrelli at Palermo for his work on the totality of prime numbers. The subject for the next award is the theory of invariants of the ternary biquadratic, considered preferably in relation to the condition for splitting into lower forms. The essays, which may be written in Italian, French or Latin, must be sent in before March 31, 1902. The next annual prize of the Madrid Academy of Sciences will be awarded for a historical memoir on the Spanish mathematicians of the 16th century.

The Peruvian Government has offered to give Harvard University additional land for its observatory at Arequipa.

Mayor Van Wyck has approved the bill passed by the Legislature enabling the city of New York to accept Mr. Andrew Carnegie's gift of $5,200,000 to erect sixty-five branch libraries.

Reuter's Agency is informed that the whaler *America* which has been bought by Mr. Evelyn B. Baldwin, the American explorer, for his forthcoming journey to the North Pole, will sail from Dundee on June 18th, by which date Mr. Baldwin expects to arrive from the United States. The *America* will proceed direct to Norway, where she will join the two other ships which are to form part of the expedition, and, after taking on board stores and equipment, will proceed North. Mr. Baldwin will, it is said, take with him 500 dogs and a number of mules. Work is now in progress for preparing the *America* for her voyage, the ship having been fitted with new masts and a new forecastle, and having been practically redecked. The vessel, formerly known as the *Esquimaux*, is an auxiliary steam whaler, and has been employed in the whaling industry for

nearly 30 years. Recently she was chartered as a private yacht, and, in addition to the accommodation usual on whalers, has had a suite of commodious cabins specially built in a deck-house aft. Her tonnage is 800, and her 100-horse-power engines give her a speed of seven knots. She is a good sea boat and well fitted to withstand Arctic ice pressure; last year while in Davis Straits she succeeded in getting out of the ice-pack from which a number of other whalers were unable to extricate themselves. Mr. Baldwin has himself left New York to join the *America*. We are unable to learn what scientific men are accompanying the expedition or what scientific work is proposed.

THE daily papers report that the department of physics of Cornell University has set up a camera with which to take each day one picture of the new anatomical laboratory in course of construction. The negatives will be taken on a long bioscopic film, and be used to produce a moving picture of the building from the beginning of its foundation to its completion.

THE *Experiment Station Record* states that the agricultural council of the Russian Ministry of Agricultural and Imperial Estates has taken steps in the direction of improving the character of the live stock and the live stock industry in general of that country. At present this industry is said to be far behind that of other countries, the animals kept being inferior and stock-raising receiving comparatively small attention from the farmers. The council has recommended the holding of live-stock shows, with prizes for excellence, the establisment of breeding farms and furnishing of expert assistance in purchasing good breeding animals, the maintenance of local breeding establishments where the service of pure-bred animals can be secured, and loans to municipalities and societies for the purpose of purchasing pure-bred animals and providing for their care. In order to carry out the above measures the Ministry of Agriculture, with the concurrence of the Minister of Finance, has recommended an appropriation of 5,000,000 rubles (about $2,000,000) to begin this work and a quadrennial appropriation of 1,125,000 rubles.

WE learn from the same source that at the third agricultural congress, held at Barbados, January 5th, Dr. D. Morris, commissioner of agriculture for the West Indies, described the progress which is being made under the Imperial Department of Agriculture in the direction of agricultural experimentation and investigation. During the year three new experiment stations have been established at Montserrat and one at Tortola for the Virgin Islands. At the present time there are 9 botanic stations maintained from imperial funds under the charge of the Imperial Department of Agriculture. In addition, there are 20 substations, or experiment plats, started at Grenada, St. Vincent, St. Lucia and Dominica to encourage the improved cultivation of cacao, coffee, limes and other crops. There are 12 central, manurial and local stations associated with the sugar-cane experiments at Barbados, 7 similar stations at Antigua and 3 at St. Kitts-Nevis. Experimental cultivation with food and other crops will be carried on in connection with all the agricultural schools. During the past year lectures to teachers in charge of elementary schools have been carried on in every part of the West Indies, and the belief is expressed that within a year or two, in the smaller islands at least, every teacher in charge of a school should be qualified, not only to give a certain amount of instruction in the principles of agriculture, but also to interest the children by simple experiments followed by practical demonstrations in the cultivation of plants suited to the district. The first agricultural school in the West Indies affording secondary education for boys was opened at St. Vincent in September, and a similar school was opened at Dominica in December, 1900. It is planned to establish two more agricultural schools during the present year, one at St. Lucia and another, combining the characters of an agricultural school and grammar school, at St. Kitts. Seven scholarships in agriculture at Harrison College, Barbados, have been established by the Imperial Department of Agriculture. Agricultural fairs have been successfully conducted, and have proved of value in stimulating effort toward better production. The Department of Agriculture has encouraged these by prizes amounting to £350 and the distribution of 100 diplomas.

UNIVERSITY AND EDUCATIONAL NEWS.

THE Minnesota Legislature has appropriated $60,000 for the College of Engineering of the State University.

THE University of Cambridge conferred last year degrees as follows: M.D., 13; Sc.D., one; Litt.D., one; Mus.D., one; B.D., three; M.A., 342; LL.M., 11; M.B., 49; B.Ch., 61; B.A., 668; LL.B., 44; Mus.B., two.

A PROPOSAL is before the German Federal Council to admit to the medical course in the University students who have certificates from the Realschule, instead of insisting as heretofore upon the classical training of the Gymnasia. The Berlin Medical Society, at a recent meeting, discussed, according to the *British Medical Journal*, this question, and passed a resolution affirming that the certificate of classical instruction should alone give the right of admission to the medical examinations, but on the proposition of Professor Virchow it was agreed to add the declaration that the admission of pupils from modern schools to the medical classes should be subject to the same rules as in the other faculties.

FOR some time there has been an agitation in Liverpool to have a university established in that city. We learn from the London *Times* that Mr. A. L. Jones, of Messrs. Elder, Dempster, and Co., has brought the subject under notice in a practical form. At a recent dinner in commemoration of the new steamer, *Sekondi*, just added to the West African fleet of Messrs. Elder, Dempster, and Co., being about to start on her maiden voyage, Mr. Jones, in proposing 'The African Trade,' said that they had a tropical school in Liverpool which had done a great deal to reduce mortality from tropical diseases, and they hoped to have a cathedral and a university. He would be delighted to see a university established, and would be pleased to give a contribution of £5,000 towards that purpose. That was not much, and he was glad to think that the contributions to follow would be much larger. Manchester men did not treat their native city as Liverpool men did. Liverpool must have a cathedral and a university, and not continue to shirk her responsibilities. Mr. A. F. Warr, M.P., in proposing 'The Liverpool School of Tropical Medicine,' said that they would not have discharged their duties until they had established a cathedral and university in the city. Professor Boyce responded, and referred to the loss sustained by the death of Dr. Myers, whose family had given £1,000 to the school, and his brother £500. They had established an absolutely international school, which had served as an example to others. Fellowships had been established at University College for the benefit of colonials and others, and the school has shown what a success a real university could be made in Liverpool.

MR. SAMUEL M. COULTER, fellow at Chicago University, has been appointed instructor in botany at Washington University.

AT Columbia University the John Tyndall Fellowship has been awarded to Mr. Berger Davis of New York and the Barnard Fellowship to Mr. J. A. Matthews of Columbia University, now carrying on chemical research in London. University fellowships in the sciences have been awarded as follows:

Robert Henry Bradford, Salt Lake City, Utah, metallurgy.

William Austin Cannon, Washington, Mich., botany.

Fellowship in chemistry to be awarded to an alternate.

William Jones, Sac and Fox Agency, Oklahoma, anthropology.

James Franklin Messenger, Cambridge, Mass., psychology.

Austin Flint Rogers, New York, mineralogy.

Walter Stanborough Sutton, Kansas City, Kansas, zoology.

Charles Partridge Weston, Orono, Me., mechanics.

James Mickel Williams, New York, sociology.

DR. E. OVERTON, docent in the University of Zurich, has been called to an associate professorship of physiology in the University at Würzburg.

DR. F. REINITZER has been promoted to a full professorship of botany in the Technical Institute at Graz.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, MAY 3, 1901.

CONTENTS:

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

HENRY AUGUSTUS ROWLAND.

IN the death of Professor Rowland, at the age of fifty-three, in the fulness of his activity and powers, the world has lost one of its foremost men of genius; America, its greatest scientist; Johns Hopkins University, the teacher and investigator who has brought it most renown.

Henry Augustus Rowland was born at Honesdale, Pennsylvania, Nov. 27, 1848; he entered the Rensselaer Polytechnic Institute, Troy, and received the degree of C.E. in 1870. After a brief experience in practical engineering on a railroad he accepted the position of teacher of science in Wooster College, where he taught physics, zoology and geology for the year 1871–2. He was then called to the Rensselaer Institute as instructor, and was soon promoted to assistant professor. He remained at Troy until he accepted a position at Johns Hopkins University in 1875. The attention of President Gilman of Johns Hopkins University was directed to Rowland by Professor Michie of West Point; and the first meeting of the two took place at the Academy on the Hudson. Before assuming the duties of his new office, at the suggestion of President Gilman, he spent a year in Europe purchasing apparatus for his laboratory, becoming acquainted with the prominent scientists of England and the Continent, and making a prolonged

stay in Berlin in order to carry out in Helmholtz's laboratory an investigation which he had long contemplated. He returned to America in 1876, was made professor of physics at Johns Hopkins, and at once began his work. His influence was immediately felt not alone in the University, but throughout the whole country; and students came from both North and South to receive inspiration and guidance. As research after research, discovery after discovery, was made, honors came from both home and abroad; his reputation and renown increased until in the whole country there was no one whose influence in all fields of scientific study or application was so great. It was in Baltimore that nearly all his great work was done, and it was here that he died on the 16th of April.

Professor Rowland was honored by being elected a member of many scientific bodies. He was Honorary Member of the Royal Society of London; Honorary Member of the Royal Society of Edinburgh; Honorary Member of the Royal Academy of Sciences, Berlin; Corresponding Member of the Royal Society of Göttingen; Corresponding Member of the Academy of Sciences of Paris; Honorary Member of the Cambridge Philosophical Society; Honorary Member of the Physical Society of London; Foreign Member of the Royal Swedish Academy of Stockholm; Associate Fellow of the American Academy of Arts and Sciences; Member of the National Academy of Sciences, and a member of nine other learned societies.

He was awarded the Rumford Medal by the American Academy in 1884, the Matteucci Medal in 1897, and received medals at the Exhibitions of Chicago and Paris. He received the honorary degrees of Ph.D. from Johns Hopkins in 1880 and of LL.D. from Yale in 1895 and Princeton in 1896. He was made an officer of the Legion of Honor in 1896.

Even as a young man, Rowland was occupied continually with problems and questions pertaining to chemical and physical science; he had his own laboratory and workshop in which he performed experiments and constructed apparatus. He read the works of Faraday and others and made their subject-matter thoroughly his own. His note-books kept when he was still a youth are full of most remarkable conjectures as to the undiscovered truths of nature, of proposed experiments, of most discriminating and accurate observations, and of many interesting theoretical discussions. It is to be earnestly hoped that the contents of these books will some day be published.

It is hardly necessary to give more than a summary of his most important researches. While at Troy he made those investigations on magnetic induction, permeability and distribution, which at once attracted the attention of Clerk-Maxwell. In Berlin he carried out his experiments on electric convection, which proved that an electrostatic charge carried at a high rate of speed has the same magnetic action as an electric current. (The results of this experiment have recently been called in question; but a repetition of the work during the past winter has confirmed them.) His first important piece of work in Baltimore was the determination of the mechanical equivalent of heat, which necessitated more careful thermometric and calorimetric methods than had ever been used before. He then became interested in questions dealing with electricity and, realizing the importance of accuracy in the measurement of electrical quantities, made a most careful determination of the ohm. This work was repeated and extended later, at the request of the United States Government.

The great problem of the connection between ether and matter was always before him, and in the desire of adding some-

thing to our knowledge he devised many experiments which were carried out by his students under his immediate direction; of these the most important were the one performed by Professor Hall, which led to the discovery of the 'Hall effect,' and those recently performed by Dr. Gilbert, which have led to purely negative results. Becoming interested in the study of spectrum analysis, largely through the influence of his colleague Professor Hastings, he realized the importance of securing as perfect gratings as possible. So he constructed a dividing engine for the ruling of gratings, the essential parts of which were a screw of nearly perfect uniformity of pitch and a most ingenious device for the correction of periodic errors. With this machine many gratings were ruled on both glass and speculum metal, the surfaces being plane. But the idea occurred to him to investigate the action of a grating ruled on a spherical concave surface; he discussed the question mathematically and thus discovered the great advantages of such 'concave gratings,' and proceeded at once to rule them. (It should be noted that all the gratings, both plane and concave, which have been ruled under Professor Rowland's direction and are now in use in all the physical laboratories of the world, have been sold at such prices as simply paid the wages of the laboratory mechanician who supervised their construction.) With these gratings the study of the solar spectrum was begun; and in order to supplement eye-observations, he made a careful study of photographic methods, and prepared his own photographic plates. Having mapped the whole solar spectrum from the extreme red to the limits in the ultra violet, he had enlarged maps prepared and offered to the world. Then he undertook the systematic study of the arc-spectra of all the elements, so far as possible; and the final results of this long research are now nearly ready for publication. Within recent years his attention had been called to the theory of alternating currents and to their application for practical purposes. He devised a system of multiplex telegraphy depending upon synchronous motors, which received a grand medal at the Paris Exposition of 1900.

These are but the most important of Rowland's contributions to science; a complete list would be even more striking. Far more important, however, than the results of the investigations themselves, is the spirit, the aim of the man as made manifest in them. His great purpose was to discover not simply the truth in nature, but the deeply hidden truth. Questions pertaining to the *fundamental* properties of electricity, magnetism, ether and matter were always in his mind; the exact measurement of spectrum lines was interesting to him only in so far as the results might lead to accurate knowledge of molecular constitution or of solar and stellar phenomena; all instruments or methods perfected by him were those which could be used to measure the *great* constants of nature.

To appreciate properly Rowland's greatness as an investigator one must have worked with him. He enjoyed to the utmost the rare gifts of intuitive knowledge and of self-confidence. His energy, his manual dexterity, his ingenuity, his keenness in perceiving and avoiding experimental errors, his skill in devising apparatus, were always evident. No scientist of this generation has had greater power than he of using his imagination under the restraints and guidance of scientific knowledge.

As the director of a great physical laboratory, Rowland was in some ways unique. His enthusiasm and the inspiration of his example were always of the greatest help; his suggestions were invaluable; but his critical powers, his deep insight into any

physical problem, his searching questions were the qualities of untold benefit. He rarely delivered a lecture without calling attention to some subject which needed experimental study; he was never present at a meeting where scientific papers were read or discussed without pointing out some error or possible improvement in the method of experimenting. He was rarely on intimate terms with his students; but no one came near him without recognizing his sweetness of character, his entire freedom from petty faults, his absolute unswerving devotion to the pursuit of truth.

J. S. Ames.
Johns Hopkins University.

*IMMUNITY AND PROTECTIVE INOCULATION.**

"When we search the history of the development of scientific truth we learn that no new fact or achievement ever stands by itself, no new discovery ever leaps forth in perfect panoply, as Minerva did from the brow of Jove.

"Absolute originality does not exist, and a new discovery is largely the product of what has gone before.

"We may be confident that each forward step is not ordered by one individual alone, but is also the outcome in a large measure of the labors of others. The history of scientific effort tells us that the past is not something to look back upon with regret—something lost, never to be recalled—but rather as an abiding influence helping us to accomplish yet greater successes."—Sir Michael Foster.

"Again and again we may read in the words of some half-forgotten worthy the outlines of an idea which has shone forth in later days as an acknowledged truth."—Sir William MacCormac.

The fact that persons once afflicted with smallpox rarely experienced a second attack of that disease when repeatedly exposed to it was not only early observed, but made a matter of record by the Chinese long before the beginning of the Christian era. That the disease was contagious had long been a matter of common experience, and the means of protection against its ravages early became an interesting subject for investigation.

The Chinese observed that when the dried and pulverized material from smallpox pustules was blown into the nostrils of persons who had not experienced an attack of the disease, the disease in persons thus infected underwent a milder course, was accompanied by a lower death rate, and conferred immunity against further attacks of smallpox. This early method of protection against the ravages of the disease became a common custom in China and India; but was later superseded by a more direct method of inoculation, that of introducing beneath the skin the scab of variolus pustules. The Chinese used the dried scab, the ordinary Hindoos the fluid pus, and the Brahmans pus that had been kept in wool for a period of twelve months. The last is clearly an instance of using attenuated virus.

It should be remembered that smallpox extended westward to Europe during the sixth century, that it reached England toward the close of the ninth century, and at the time of the Crusades became widespread. In 1517 it was carried from Europe to Santo Domingo; reached Mexico in 1520, whence it spread throughout the New World. It was introduced into Iceland in 1707 and to Greenland in 1733.

It should be particularly noted, that in the invasion of new territory the virulence of smallpox at once became greatly intensified—in some instances nearly one-half the population being destroyed by it. Robertson records the death of three million and a half of people in Mexico alone as the result of the invasion of 1520. Again, the dark-colored races seem to be more easily infected than Europeans.

The protective method of directly inoculating the pulverized variolus scab beneath the skin slowly traveled westward; so

* Address of the President of the Texas Academy of Science, given in the Chemical Theater of the University of Texas, on October 26, 1900.

slowly, that it did not reach Western Europe until 1718, when Lady Mary Wortley Montagu introduced the process then in vogue in Constantinople. While the year 1718 marks the introduction of protective inoculation to the aristocracy of England, the practice had come into use among Scotch and Welsh peasants at a much earlier date, which probably accounts for the next stage in the evolution of measures of protection against infectious diseases.

Herdsmen and milkmaids in both England and Schleswig-Holstein observed that occasionally on the udder of cows there appeared an eruption resembling smallpox; that this eruption could be communicated to persons engaged in milking; and that persons infected with the cowpox were protected against an invasion of true smallpox. The fact that the notorious Mrs. Palmer, Duchess of Cleveland, was thus protected is evidence sufficient to show that such observations were common as early as 1663. In 1768 Fewster and Sutton in London; 1774, Jesty, a Dorsetshire farmer; 1791, Pless, a Holstein teacher, and May 14, 1796, Jenner, confirmed these observations. It is true that the immortal work of Jenner began as early as the year 1769; for at this time, while a student under John Hunter, he heard a young country woman, in whose presence the subject of smallpox was mentioned, say: "I cannot take that disease, for I have had cowpox." Upon mentioning the subject to his master, Hunter replied "*Do not think, but try; be patient, be accurate.*" Jenner did try; was patient, was accurate; and on May 14, 1796, after years of patient labor, in his 'Inquiry into the Causes and Effects of the Variolæ Vaccinæ,' he experimentally established the following facts:

1. That this disease (cowpox) casually communicated to man has the power of rendering him unsusceptible of smallpox.

2. That the specific cowpox alone, and not other eruptions affecting the cow, which might be confounded with it, had this protective power.

3. That the cowpox might be communicated at will from the cow to man by the hand of the surgeon, whenever the requisite opportunity existed. And

4. That the cowpox once ingrafted on the human subject, might be continued from individual to individual by successive transmissions, conferring on each the same immunity from smallpox as was enjoyed by the one first infected direct from the cow.

Thus it is seen that Jenner, by inoculating a cow with variolus matter produced in the cow an eruptive disease resembling smallpox, but of a milder type, and that the cultivation of this milder disease in the cow yielded a fixed virus (vaccine) which, transplanted to man, gave rise to a still milder eruptive disease (vaccinia) possessing constant characteristics, and conferring upon persons who underwent it immunity against smallpox.

The older methods of inoculation against smallpox were quickly supplanted by the simpler and far safer method of vaccination; and since the introduction of the latter the appalling ravages of smallpox have been relegated to historical literature.

The subsequent development of vaccination is a matter of such general information that there is no need of its further discussion here. It is sufficient to say that in the great majority (if not in all) of the cases of successful vaccination immunity against smallpox is conferred for an indefinite period, varying from three years to many years—averaging three to seven years—in some cases for life; and that compulsory vaccination and revaccination offer the safest and surest protection against this loathsome disease.

The success of vaccination gave great impetus to the investigation of the problem of immunity, and the annals of the nineteenth century contain a voluminous record of the prolonged and patient efforts of a host of brilliant workers whose contributions have at least laid the foundation upon which the

solution of the problem may, in the future, be built. The building of this foundation can not be recounted here; but it will be necessary to mention some of the materials of which it is made, that the latest progress may be intelligently discussed.

As in the case of smallpox, it had long been a matter of common observation that a number of the acute infectious diseases occur but once in the same individual. Whooping-cough, measles, scarlet-fever and yellow-fever are notable examples of acute infectious diseases one attack of which usually confers immunity against subsequent attacks of the same disease. It was also observed that some infectious diseases confer a very evanescent type of immunity, and that others confer no immunity whatever.

From the standpoint of immunity the infectious diseases may be easily divided into three classes:

1. Diseases one attack of which confers immunity against subsequent attacks of the same disease.

2. Diseases one attack of which confers immunity against subsequent attacks of the same disease for only short periods of time.

3. Diseases an attack of which confers no immunity whatever.

It would seem that these facts, coupled with Jenner's discovery of a fundamental and practical method of producing artificial immunity, clearly outlined the path for future workers to follow; but, strange to say, the nineteenth century was well on its way before this important route found many followers.

The failure to appreciate fully Jenner's brilliant discovery, and to apply his method to the study of other infectious diseases, finds an explanation in the hazy theoretical conceptions of the cause and nature of infectious diseases which prevailed during the early part of the century. The investigations of fermentation by Astier, Sette, Franz Schulze, Cagnaird de Latour, Schwann, Fuchs, Remak, Mitscherlich, Helmholtz and others did much toward clearing the haziness of that period; but it was the monumental work of Pasteur that 'finally established the truth of the view that all processes of fermentation and putrefaction alike are caused by living things, and that in each different fermentation different kinds of microbes are concerned.' In the light of newer knowledge this statement needs revision. The investigations of Koch on anthrax soon followed, and then came the growth of pure cultures of several pathogenic bacteria.

"The work of Pasteur and Koch afforded the first basis on which the study of artificial immunity could be again undertaken. The possibility of voluntarily producing a number of the most important infectious diseases of men and animals, and of modifying at will pure cultivations of bacteria, either, according to Jenner's precedent, by passage through the animal body, or otherwise on artificial culture media, laid the foundation on which advancement could proceed. Pasteur himself was the first, after Jenner, to produce an artificial immunity by using an attenuated virus; and he was also able to introduce the procedure to some extent into practice with most beneficial results. Still the theoretical explanation of all these facts lagged far behind their practical effects. The very able investigations of Metschnikoff and his theory of phagocytosis were, to many investigators, inconclusive."

Numerous attempts were made to formulate adequate theoretical explanations of the accumulated facts concerning the phenomena of infectious diseases. The followers of Sydenham looked upon the specific disease itself as an *entity;* while Lotze and Virchow viewed it as a *process.* It was clear that a mechanical or dynamical process could not be a living entity. The

physiologists Haller, Reil and Johannes Müller had established this principle for normal life processes, and its extension to abnormal life processes was simple enough. "Whatever be the outside forces that act, the eye perceives only light, and the ear only sound; the glands simply secrete and the muscles contract. It is, therefore, the internal condition of the organism, of its organs, tissues or cells, that alone determines the character of the effect. The impulse that must come from the outside to produce these effects is called the stimulus. Hence there must exist a fundamental internal organization, that is to say, a predisposition to something external. * * * Disease, then, may be regarded as the effect produced by quantitative changes in normal conditions, either when the physiological organization is too feeble or the stimulus too intense." Disease may be viewed as a phenomenon of adaptation.

Against this conception, the parasitic or germ theory, developed by Plenciz, Eisenmann, Henle, Davaine, Pasteur, Klebs, F. Cohn, J. Schröter and Koch, appeared to introduce an entirely new qualitative element. It asserts 'that many diseases are due to the presence and propagation in the system of minute organisms having no part or share in its normal economy.'

Another conception is that of Pettenkofer, which holds that the determining cause is to be found in the external conditions, which vary according to time and place.

It is not difficult to see that these theories are upholding entities as the cause of disease. While a kernel of truth is to be found in each, they all fail to realize the continuity of causes in the sense of modern exact science. "The true and sufficient cause of any effect is always something internal, something that follows from the kind and amount of initial energy, and from that quality and quantity alone and entirely. * * * It is the absolute thing 'that exists behind all change and remains primordially the same,' as Helmholtz expressed it." Or as the modern physicist would put it: potential energy = cause, kinetic energy = effect; and as a liberating impulse will change potential energy into kinetic energy, so a liberating impulse will change cause into effect.

The cloudiness that characterizes many of the theories that have sought to explain the phenomena of infectious diseases is largely a legacy of Kantism, and is clearly out of place in these days of modern science. It is somewhat strange that 'ontological toys' are still to be found in the workshop of some really brilliant investigators of natural phenomena. Nevertheless, they are there —which explains some explanations that do not explain.

The parallelism which subsists between the phenomena of fermentation, infection and immunity, suggests the mental route to be traveled if an insight into our problem is to be gained; and for this reason it is necessary to first point out a few facts about fermentation.

FERMENTATION.

If the phenomena of matter be defined as periodic functions of the atomic and molecular masses which constitute it and the rates of motion of these masses, and the chemical unit be viewed as a 'center through which energy manifests itself,' then the theories of modern chemistry should supply an explanation of the phenomena of fermentation.

The crucial test of every theory which seeks to explain fermentation is the satisfactory explanation of the following phenomena:

Enzymes appear to be capable of disrupting complex chemical bodies without undergoing any apparent chemical change themselves—that is, they bring about a

chemical change in disproportionately large quantities of material. When the newly produced substances attain a certain concentration the further action of the enzyme is inhibited, but its action is reasserted when the concentration of the zymolytic products is again lowered. Maximum, minimum and optimum temperature and pressure influence these changes. The introduction of certain chemical bodies also exerts an accelerating or retarding influence; and phenomena of *selective* action are likewise to be found.

Many hypotheses have been submitted. Very ingenious explanations of some of the phases of fermentation are to be found in them; but under the searching light of completer knowledge their incompleteness is sooner or later developed. Many of the modern theories are little else than translations of the earlier hypotheses into terms of modern scientific terminology, so that the later literature is laden with modern extensions of the catalytic theory of Berzelius, Beal's bioplastic theory, Justus von Liebig's physical theory, the germ theory, etc.

Interesting and enlightening as some of these theories are, their full consideration is not within the purpose of this address, the limits of which will permit only a brief and incomplete review of some of the more modern conceptions of fermentation, to which attention is now asked.

The more recent investigations of the organized and unorganized (soluble) ferments have dealt a severe blow to the vitalistic theory of fermentation. Hansen's admirable biological researches upon the yeasts, followed by the important investigations of Buchner, A. Croft Hill, Emil Fischer and many others brought to light many interesting hitherto hidden facts; and it now seems clear that all the phenomena of fermentation may be explained from a purely chemical basis. The so-called organized ferments appear to be 'active proteids,' and the unorganized ferments, or enzymes are mostly proteid-like bodies presenting great differences in the complexity of their chemical structure.

Hueppe looks upon 'active proteid' as "a kind of intermediate stage between lifeless 'nutritional' proteid and living cells"; that it 'appears like an anhydride of dead proteid,' inasmuch as hydration converts it into an inactive form. Investigations of Bokorny and Loew demonstrated the existence of active proteid in many plants. Loew speaks of it as reserve protein matter of a highly labile nature, and that it differs from all other reserve proteins. He called it proto-protein, and suggested that it is the 'material which, by being converted into organized nucleo-proteids, forms living matter.' Protein comprises all kinds of albuminous matter, while proteid is used to designate complex compounds of proteins, such as nucleins, hæmoglobin, etc. *Labile* chemical compounds are unstable bodies which easily undergo chemical change. Labile atoms or groups of atoms are atoms or groups of atoms which readily migrate from a center of instability to one of stability. When the migration is intramolecular a stereoisomeric compound is the product of change; when the migration is extra- or intermolecular disruption of the molecules takes place. Loew points out the necessity of distinguishing between 'potentially labile and kinetically labile compounds; in other words, between static labile and dynamic labile'—using the potential chemical energy in the sense of intramolecular chemical energy. Nitroglycerole and certain other explosive organic compounds represent the potential type, while examples of the kinetic are found in the aldehydes and ketones.

The energy stored in a labile compound is beautifully illustrated in the explosion of the trinitrate of glyceryl—$CH_2(ONO_2).CH$

$(ONO_2).CH_2(ONO_2)$, which when heated to 257° C., or when struck, explodes with great violence. The products of the decomposition are represented by the equation:

$$4C_2H_5.(NO_3)_3 \Longrightarrow 12CO_2 + 10H_2O + 6N_2 + O_2.$$

At the temperature of the explosion all these products are gases, and at atmospheric pressure will now occupy the space of about 10,400 liters, having expanded about 18,324 times its original volume.

Another instance is that of mercury fulminate $[(C:N.O)_2Hg + \frac{1}{2}H_2O]$, which develops a pressure of 43,000 atmospheres by detonating in its own volume.

Chemical changes partially or completely destroy the statically labile compounds, while the dynamically labile compounds readily pass into isomeric or polymeric compounds as a result of atomic migrations, or by polymerization. The classic illustration usually given of the production of an isomeric compound produced by atomic migration is Wœhler's famous discovery: the transformation of ammonium cyanate into urea, which he accomplished in 1828, by evaporating an aqueous solution of ammonium isocyanate. The transformation is represented by the equation:

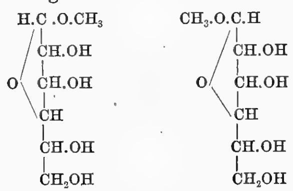
$$O:C:N.NH_4 \Longrightarrow O:C{<}^{NH_2}_{NH_2}.$$

Many others can be cited.

Noting that labile compounds are more easily attacked by chemical agents than stable ones, Loew has elucidated the action of many poisons. He says: "A systematic toxicological review shows us among other things that all compounds acting upon aldehydes and all that easily attack labile amido-groups are poisonous for all kinds of living protoplasm, which fact led me to infer that the lability of the plasma proteids is caused by the presence of aldehyde and amido-groups within the same molecules. * * * The *primum movens* in the living protoplasm must be defined as a mode of motion of labile atoms in the plasma proteins; that is, as a *special case of chemical energy.*" According to Loew, the enzymes belong to the dynamically labile compounds.

While the chemical structure of the enzymes is not yet known the researches of Emil Fischer go to show that a knowledge of their constitution is not far beyond our reach. In the fermentation of the sugars Fischer has shown that the enzymes can only 'attack those sugars which possess a molecular configuration corresponding to their own'—that is, they must fit each other 'as the key fits its lock.' Viewing the enzymes as nucleo-proteid bodies, and as being optically active, he reasoned that *their molecules must have an asymmetric structure.* Their selective action toward α and β methyl-glucosides strongly supports this view.

According to Fischer, two methyl-glucosides are formed by the action of hydrochloric acid (HCl) on a solution of *d* glucose in methyl alcohol, and their configuration is given as follows:



One is called α the other β, and their difference is found in the configuration of the one asymmetric carbon atom, yet the enzymes which attack the α will not attack the β, and *vice versa.* This important discovery sheds a world of light upon the vexed problem of fermentation, and will therefore help to explain many of the obscure phenomena of disease and of immunity. It will also find a place in the investigation of many of the difficult problems of physiological chemistry. A very admirable feature of Fischer's hypothesis is its capacity to receive aid

from, and give aid to, several other hypotheses—it possesses a wide range of applicability.

In 1892, our esteemed colleague, Professor J. W. McLaughlin, in his book on 'Fermentation, Infection and Immunity,' elaborated a 'Physical Theory,' a quotation from which is here presented. After developing the modern conception of complex molecules, Dr. McLaughlin goes on to say: "When we add to this conception of atomic and molecular union, that of atomic vibrations in unvarying periods of time which are distinctive of each kind of atom, and that of ethereal wave-motions vibrating in equal periods with the atoms that produce them, the law of 'interference' enables us to understand how atomic wave-motions may be supplemented or antagonized by other atomic wave-motions, and how molecular wave-motions may, likewise, be similarly influenced by other molecular waves; that, in fact, the molecular waves which give a substance its energy will vary with molecular grouping. Now it is in these principles of molecular dynamics, and in chemistry and biology, that, we believe, is to be found the explanation of cell metabolism—constructive and destructive—of fermentation, of infection and immunity." On page 66, he says: "It is only when the molecular vibrations of a ferment, whether this be a living, organized ferment, or a non-living, unorganized ferment, coincide with those of a fermentable substance, that the latter may be disrupted by the former, and fermentation ensue." While these two quotations do not adequately present Dr. McLaughlin's theory, they suggest a connecting link with the physical hypothesis of de Jager.

"Starting with Naegeli's view that fermenting yeast-cells emit vibrations which pass out of the cells and decompose the sugar in the solution surrounding them, de Jager suggests that the enzymes may be regarded not as substances at all, but as the vibrations themselves; that is as properties of substances rather than material bodies." He compares them to light, electricity, magnetism. Fermentation does not depend upon chemical action of a molecular substance, but chemical transformations are brought about by physical forces. Maurice Arthus has very ingeniously elaborated the theory of de Jager.

O'Sullivan and Tompson have shown that invertase is capable of inverting more than 100,000 times its own weight of cane sugar without exhausting itself; and Tamman proved that under proper conditions the enzyme is decomposed during its activity with extreme slowness. These reactions find their parallel in the action of nitric oxide in the manufacture of sulphuric acid, and in the action of sulphuric acid in the production of ethyl oxide; and Bredig and von Berneck have recently shown that "one gram-atom (193 grams) of colloidal platinum diffused through seventy million liters of water shows a perceptible action on more than a million times the quantity of hydrogen peroxide."

In these four instances it will be observed that the invertase, nitric oxide, sulphuric acid, and colloidal platinum acted solely in the capacity of catalyzers, that is, they modified the time factor of the reaction—the positive catalyzers accelerating, and the negative catalyzers retarding, the velocity of the reactions. Catalyzers, then, serve in the capacity of *liberating impulses.*

That zymohydrolysis is a chemical action finds further support in the recent work of A. Croft Hill on 'Reversible Zymohydrolysis.' By varying the concentration of mixtures of glucose and maltose he found that the equilibrium point of these two sugars was reached when 85.5% of glucose and 14.5% of maltose were present. Increasing the glucose beyond 85.5% sent the hydrolysis one way, and the reaction reversed

when the maltose was increased beyond 14.5%. This is in strict conformity with the law that "*every reaction proceeds to a state of equilibrium, with a definite reaction velocity.*"

The phenomena of reversible reactions have been well worked out, and Konowalow's reaction of acetic acid upon pentene:

$$CH_3CO.OH + C_5H_{10} \rightleftarrows CH_3CO.O(C_5H_{11}),$$

has been shown to conform to the requirements of the law of mass-action by Nernst and Hohmann.

Another very important observation made by Bredig and von Berneck is that "relatively minute portions of certain substances are able to inhibit the catalytic action of platinum, and that these are substances which exert a markedly poisonous effect on the living cell and on enzymes. 1/345,000 gram-molecule per liter of hydrogen sulphide already exerts a strongly restraining action. 1/1,000 gram-molecule per liter of hydrocyanic acid stops it entirely, and much less is able to retard it greatly. Carbon disulphide, and mercuric chloride show a similar behavior." This again parallels the action of ferments and antiferments.

Were it necessary, many other interesting parallels could be drawn to show the intimate connection between the phenomena of fermentation and the phenomena of chemical action; but this must suffice to authorize the statement that the complex phenomena of fermentation can be best understood when viewed from the pinnacle of modern chemical theory—the Avogadro-van't Hoff rule, the phase rule, electrolytic dissociation and the doctrine of energy.

Having shown that chemistry helps us to understand fermentation, let us see what light it is capable of shedding upon infection.

INFECTION.

The fact that the poisonous action of the bacteria is due to the soluble products formed by the bacteria was established by Panum in 1874. Later, Koch, Chauveau and others succeeded in separating these poisons from the bacteria, and by inoculating animals with them proved that the proliferation of a number of pathogenic organisms in the body was less injurious to the body than the soluble poisons produced by them. Brieger viewed these poisons as organic bases, the so-called ptomaïns; but, subsequently some of them were shown to be either proteid or proteid-like bodies, and many of them acted not unlike digestive ferments. Brieger and Fränkel named the proteid-like bodies toxalbumins. Among the toxins are uncrystallizable poisons, the complex chemical structure of which has not yet been made out. The ptomaïns are crystallizable products of bacterial activity somewhat analogous to the vegetable alkaloids. Some possess toxic properties, while others do not. The chemical structure of some of them is well known, but the structure of toxalbumins is a problem for future work.

In his work on 'Ptomaines and Leucomaines,' Vaughan points out a very interesting chemical relationship between some of the non-poisonous and poisonous members of the cholin group. Starting with trimethyl-ethyl-ammonium hydroxide, by oxidation cholin, neurin, betaïn and muscarin are derived as follows:

$$\begin{array}{lcl} CH_3 & & CH_2.OH \\ | & & | \\ CH_2 & + O \longrightarrow & CH_2 \\ | & & | \\ N(CH_3)_3OH & & N(CH_3)_3OH; \end{array}$$

(Trimethyl-ethyl-ammonium hydroxide.) (Cholin.) (Oxyethyl-trimethyl-ammonium hydroxide.)

$$\begin{array}{lcl} CH_2.OH & & CH_2 \\ | & & \| \\ CH_2 & - H_2O \longrightarrow & CH \\ | & & | \\ N(CH_3)_3OH & & N(CH_3)_3OH; \end{array}$$

(Cholin.) (Neurin: Vinyl-trimethyl-ammonium hydroxide.)

$$\begin{array}{lll} CH_2.OH & & CO.OH \\ | & & | \\ CH_2 & +O_2 \Longrightarrow & CH_2 \\ | & & | \\ N(CH_3)_3OH & & N(CH_3)_3OH; \end{array}$$

(Cholin) (Trimethylglycocoll)

$$\begin{array}{lll} CH_2.OH & & CH_2.OH \\ | & & | \\ CH_2 & +O \Longrightarrow & CH.OH \\ | & & | \\ N(CH_3)_3OH & & N(CH_3)_3OH. \end{array}$$

(Muscarin: Dioxyethyltrimethyl-ammonium-hydroxide.)

The structural formulæ show the little change that is necessary to convert an innocuous substance into a very poisonous one, and *vice versa*. Cholin is only poisonous in large doses while very small doses of neurin and muscarin are highly poisonous. Betaïn is not poisonous.

Methylguanidin $\left(NH : C<^{.NH_2}_{.NH}(CH_3)\right)$, trimethylenediamine $\left(CH_2 : <^{CH_2.NH_2}_{CH_2.NH_2}\right)$, and tyrotoxicon (diazobenzene-potassoxide, $C_6H_5.N_2.OK$) are three other poisonous ptomaïns whose chemical structure is well known. Typhotoxin ($C_7H_{17}NO_2$) is said to be the toxin which gives rise to the typhoid intoxication, and Brieger has been able to separate from tetanus cultures four bases: tetanin ($C_{13}H_{30}N_2O_4$), tetanotoxin ($C_5H_{11}N$), spasmotoxin and one other unnamed toxin. According to Brieger, each of these is capable of inducing tetanic intoxication. Against this last statement is opposed the further statement that tetanus toxin is a toxalbumin.

Roux, Yersin and others succeeded in isolating, seemingly in a state of purity, from the cultures of the Klebs-Loeffler bacillus a toxalbumin, soluble in water, which when inoculated into a guinea-pig produced the phenomena characteristic of diphtheria. Prosecuting this line of investigation, these and other investigators have isolated characteristic toxalbumins from cultures of other germs. These toxalbumins have been divided into two principal groups by Brieger and Fränkel, the classification being based upon their solubility. As previously stated, they are proteid-like bodies, highly complex and poisonous. Their further properties may be considered later; but in passing, an idea of their virulence should be given.

"A tetanus toxin has been prepared, of which 0.00005 milligram killed a mouse weighing 15 grams; a man weighing 70 kilograms, with the same susceptibility, would be killed by 0.23 milligrams. This would make the poison 300 times more potent than strychnine."

Closely related to the toxins which arise as products of bacterial activity there is another group of toxic substances which arise in the living animal tissues as the products of either hyper or of retrograde metabolism of the protoplasm, or result from fermentative action. Some of these are proteid-like bodies (toxalbumins), while others are organic bases (leucomaïns) not unlike the vegetable alkaloids.

The chemical structure of many of the leucomaïns is well known; but the same cannot be said of the toxalbumins. The development of their structure must await the unraveling of the proteids—their chemistry seems to flow in channels parallel with the chemistry of the albumins, globulins, albuminates, proteoses and peptones. At least the poisonous principle clings to these products.

The venom of the snake belongs to this class. According to the researches of S. Weir Mitchell, E. T. Reichert, T. R. Fraser and others, snake venom is a very complex mixture containing in addition to the poisonous substances several bodies that are non-poisonous. The poisonous substances are not ferments. Fraser says: "They are substances that produce effects having a direct relationship to the quantity intro-

duced into the body. This quantity in the case of each serpent varies with its size and bodily and mental condition; with the nature of the bite—whether both fangs or only one has been introduced, whether they have penetrated deeply or only scratched the surface; and with other circumstances related to the serpent, such as whether it had recently bitten an animal or not, and thus parted with a portion or retained the whole of the venom stored in the poison glands. The quantity required to produce death being very exactly related to each pound or kilogram of weight." Fraser found the minimum lethal dose per kilogram to be: "For the guinea-pig (of dried venom), 0.00018 gm.; for the frog, 0.0002 gm.; for the rabbit, 0.000245 gm.; for the white rat, 0.00025 gm.; for the cat, somewhat less than 0.005 gm.; and for the grass snake (*Tropedonotus natrix*), the relatively large dose of 0.03 gm."

It is significant that the toxicity of cobra venom is not the same for all animals. Furthermore, it is exceedingly interesting to find that the experiments carried out by Fraser, *in vitro* and in the animal organism, leave practically no room for doubt that the poisonous action of snake venom and the antagonistic action of antivenin are both chemical. In the unprotected animal snake venom injected beneath the skin or into the blood stream gives immediate evidence of reactions of an endothermic character; but when in the same manner it is introduced into protected animals evidence of exothermic reactions is elicited. When introduced into the stomach of an animal snake venom not only fails to induce symptoms of poisoning, but exhibits a neutralizing action upon inoculated venom, and in the uninoculated animal confers immunity against snake venom. Moreover, the ratio between venom and antivenin is quantitatively brought out in the experiments of Fraser. All this can be shown to be in conformity with well-known chemical laws.

Numerous examples which illustrate the chemical nature of the action of toxalbumins might be drawn from various intra- and intercellular protoplasmic bodies found in the vegetable and animal kingdom, but time will not permit their multiplication here. A bountiful supply is to be found in recent biochemical and medical literature, and interested persons are referred to that source.

The specific phenomena of these poisons as exhibited in the human body when toxic quantities are taken will be found in nearly every text-book of modern medicine, so there is no need to repeat them here.

What has been said of the chemistry of fermentation is equally applicable here. Specific illustrations and their enlargement just now would take us beyond the limits of this address; for that reason it is well to pass on to the consideration of the next phase of the subject.

IMMUNITY.

The problem of immunity is so closely entwined with that of protective inoculation that it will be easier to discuss the two conjointly.

In its broadest sense, immunity represents that state of the living organism (animal or vegetable) which enables it to resist the toxic action of substances, whether such substances be introduced from an external source or are developed within the organism. Specific immunity is a state of immunity against a specific substance. This may be *natural*, as when the organism is normally *non-susceptible;* or it may be *artificial* (acquired), as in the case of protection against disease developed by a previous attack of the disease (as in smallpox), or by some other artificial means (vaccination, for instance).

Vexed as the problem is, much enlightenment is to be gained from an investiga-

tion of artificial immunity. Recalling the researches of Jenner, and the quotation from Ehrlich relative to the work of Pasteur, at that time it appeared as though artificial immunity was brought about by specific micro-organisms. Opposed to this view the investigations of Toussaint, Chauveau, Salmon and Smith, Roux, C. Fränkel and others brought forward evidence to show that artificial immunity could be induced by the 'metabolic products' freed from bacteria—accustoming the organism to the specific poison seemed all-sufficient. Later it was shown by Hueppe, Gamaleia and Buchner that the specific toxins found in the culture fluid outside the bacterial cells were not identical with the protective substances found in the germs and their metabolic products.

At this point Hueppe says: It has been "established that: (1) undergoing the disease; (2) inoculation with attenuated germs; (3) inoculation with disease germs which have become wholly impotent; (4) inoculation with saprophytes, and (5) inoculation with the metabolic products of the parasite, can all confer immunity; while, (6) inoculation with the specific poisons effects no immunization." Then followed the experimental proof that completely attenuated bacteria can no longer produce the specific poison. This effectually separates the protective substance and the poison.

The next important advance was the discovery of substances in the blood serum of animals immunized against diphtheria and tetanus that were able to specifically protect other animals against the toxines of these diseases. This discovery was made by Behring, and it at once opened an entirely new and promising field for investigation.

December 3, 1890, in No. 49 of the *Deutsche med. Wochenschrift*, Behring and Kitasato published an article: 'Ueber das Zustandekomen der Diphtherie-Immunität und der Tetanus-Immunität bei Thieren' in which the statement is made that: "The blood of tetanus-immunized rabbits possesses the property of destroying tetanus toxin. This is possessed by the extravascular blood and is the cell-free serum." They showed that the blood serum of non-immunized animals did not possess this antagonizing action, and that the prepared serum was of therapeutic value. Ogata and Jasuhara proved that blood serum from an animal naturally immune contained substances which, when injected into mice, conferred upon them the same type of immunity. Tizzoni and Cattani (1891) found that the quantitative protective value of the blood serum of animals naturally immune to tetanus (the dog, for instance) could be greatly increased by repeated injections of gradually increasing amounts of tetanus-toxin; and that such serum possessed decided therapeutic value when inoculated into animals suffering from tetanus. This line of investigation has been greatly extended and enriched by Behring, Roux, Koch, Yersin, Haffkine, Pfeiffer, Buchner, Sanarelli, Ehrlich and others, and, as a result, there is to be found in the open market to-day a variety of antitoxin sera, such as antidiptheritic, antitetanic, Marmoreck's antimycotic, antipneumococcic, antibubonic, antirhabic, yellow-fever, etc.

March 20, 1896, Professor Thomas R. Fraser, M.D., at the Royal Institution of Great Britain, presented a very important contribution on 'Immunisation against Serpents' Venom, and the Treatment of Snake-bite with Antivenene,' in which, for the first time, the quantitative relation between the 'toxic' and the 'anti' substances is shown. The contribution is rich in splendidly marshaled experimental evidence which leads the author to the logical conclusion that, so far as snake venom is concerned, the antidotism of the 'antivenene' is not the result of physiological reaction, is not due to phagocytic action, nor to the

'resistance of tissues,' but, as I have already pointed out, a chemical theory, implying a reaction between antivenene and venom, which results in a neutralization of the toxic activities of the venom, is entirely compatible with the observed facts.

Another significant fact of chemical importance observed by Fraser is that, in carrying out the immunizing process, "the saturation point of the blood for antivenene is reached before the possible maximum non-fatal dose of venom has been administered." The protective value of venom and 'antivenene' when administered by the stomach has already been mentioned.

By this time the use of diphtheria antitoxin as a therapeutic agent in the treatment of diphtheria had become firmly established. The variation in the results obtained caused Ehrlich to search for a quantitative relation between the toxin of diphtheria and the antitoxin of diphtheritic serum. The result of Ehrlich's investigation is to be found in the Croonian lecture delivered by him before the Royal Society, London, March 22, 1900. 'By means of test-tube experiments with suspended animal tissues' he brought out some very interesting facts. "The relations were simplest in the case of red-blood corpuscles. On them, outside the body, the action of many blood poisons, and of their antitoxins, can be most accurately studied, *e. g.*, the actions of ricin, eel-serum, snake poison, tetanus toxine, etc. * * * By means of these test-tube experiments, particularly in the case of ricin, I was able, in the first place, to determine that they yielded an exact quantitative representation of the course of the processes in the living body. * * * It was shown that the action of toxine and antitoxine took place quantitatively as in the animal body. * * * It was proved in the case of certain toxines—notably tetanus toxine—that the action of antitoxines is accentuated or diminished under the influence of the same factors which bring about similar modifications in chemical processes —warmth accelerates, cold retards the reaction, and this proceeds more rapidly in concentrated than in dilute solutions. * * * The knowledge thus gained led easily to the inference that to render toxine innocuous by means of antitoxine was a purely chemical process, in which biological processes had no share."

The distribution of the toxins and the antitoxins in the system is a matter of prime importance, yet not more than a beginning has been made looking toward their localization. That they do possess a selective action has been established by Stokvis, Dönitz, Pfeiffer, Marx, Wassermann and Roux, and these facts throw a great deal of light upon the phenomena of incubation, time reactions, antitoxic action, protective action, serum therapy, etc.

The phenomena of agglutination and lysogenic action, the recent work of Buchner in Germany and Bordet in France, on hæmolysis, and some experimental work on ionic reactions done in my own laboratory, deserve consideration here; but time presses for a summation, and they must be passed without further comment to a future occasion.

From accumulated facts, *acquired immunity* is separable into two distinct types. (The following classification is borrowed from Muir and Ritchie.)

A. Active immunity, *i. e.*, produced in an animal by an injection, or by a series of injections, of non-lethal doses of an organism or its toxines.
  1. *By injection of the living organisms.*
    (*a*) Attenuated in various ways. Examples:
      (1) By growing in the presence of oxygen, or in a current of air.
      (2) By passing through the tissues of one species of animal (becomes attenuated for another species).
      (3) By growing at abnormal temperatures, etc.
      (4) By growing in the presence of weak antiseptics, or by injecting the latter along with the organism, etc.

(b) In a virulent condition, in non-lethal doses.

2. *By injection of the dead organisms.*

3. *By injection of filtered bacterial cultures, i. e., toxines; or of chemical substances derived from these.*

These methods may also be combined in various ways.

B. Passive immunity, *i. e.*, produced in one animal by injection of the serum of another animal highly immunized by the methods of A.

1. *By antitoxic serum, i. e.*, the serum of an animal highly immunized against a particular toxine.

2. *By antimicrobic serum, i. e.*, the serum of an animal highly immunized against a particular organism in the living and virulent condition.

The protective value of active immunity extends through a considerable period of time, while that of passive immunity is evanescent.

An adequate explanation of this vast array of facts is yet before us. The explanation in detail cannot be given to-night; that must await another time; but some generalizations must be made.

1. *Pasteur's theory of exhaustion* of the pabulum is disproved by the fact of passive immunity.

2. The *theory of retention* will have to be greatly modified before it can explain many facts with which it is now in opposition.

3. The *theory of acclimatization or habituation* has limited application and, like the theory of adaptation, takes too little cognizance of details.

4. *Metchnikoff's theory of phagocytosis* falls before the facts of passive immunity; and

5. The *humeral theory* only presents another phase of its own evolution.

6. *Buchner's hypothesis*, which explains immunity as being due to the reactive changes in the integral cells of the body resulting from the action of chemical products absorbed from the seat of vaccination or inoculation, is strongly supported by experimental evidence; and

7. *Ehrlich's side-chain (Seitenkette) theory* presents an exceedingly ingenious and interesting explanation of the phenomena of immunity adduced by experiments *in vitro* and *in vivo*.

By elimination the problem may be somewhat simplified. The facts themselves may be roughly divided into two groups: (1) biological, and (2) chemical; and the explanations will then be either biological or chemical. In the ultimate analysis, the biological explanation will rapidly pass from the body as a whole to its respective organs and their respective cells, to the nucleated cells, and finally to the biogen of the nucleus; while the chemical explanation will describe the cycle that begins with the minutest atomic reaction, passes onward through more and more complex intra- and intermolecular synthetic and analytic changes so long as chemical equilibrium is disturbed; but eventually finds its beginning and its end—cause and effect—in energy potential, energy kinetic, liberating impulse.

That the problem of immunity will be solved is only a question of time. The active research now in progress is rapidly dissipating the unknown; and when the chemical structure of the various animal proteids becomes a known quantity their interaction will be readily seen and the solution of the problem will be an accomplished fact.

The problem is a biochemical one, and biochemists will solve it. Many, if not all, the phenomena of fermentation, infection and immunity are explainable in terms of modern chemistry, and since modern chemistry is firmly founded on the doctrine of energy we have to consider merely the terms, *energy potential*, *energy kinetic* and *liberating impulse.*

I am conscious of having failed to bring before you a large mass of newly accumulated, interesting facts which should be considered in this connection; but the largeness of the subject together with the enormous accretions annually made to its

literature renders it impossible to present a complete survey of so immense a field of labor in the address of an evening. What has been said is little more than a beginning of what has been done in this line of biochemical research—the promise of its future remains to be told.

Beside the great intellectual gain must be placed the immense practical benefits such investigations have secured for man—as witnessed in the saving of millions of lives of human beings, many times more of the lower animals, and large areas of plant life. They have ever made for the betterment and happiness of man, and for the highest progress of civilization, and so will they continue.

HENRY WINSTON HARPER.

AN ELECTROCHEMICAL LABORATORY AT THE UNIVERSITY OF PENNSYLVANIA.

THE great importance of electricity in chemistry is universally recognized. Universities and technical schools are rapidly adding appliances for the use of this agent to their chemical equipments. Here, at the University of Pennsylvania, the first work done in electrochemistry was in the year 1878. It consisted in the precipitation of cadmium from its salts, also the separation of this metal from copper, and the precipitation of uranium as protosesquioxide by the electric current. Since that time numerous other methods have been devised, and the practical work has been greatly amplified and incorporated in the course of chemical instruction designed for undergraduate and graduate students in chemistry.

The electric energy was, at first, derived from various types of primary batteries, but as the demand for powerful and steady currents grew, several storage cells of the Julien type were introduced, early in the year 1888, and constantly used until 1895, when the equipment was increased by the addition of twelve chloride accumulators (Type E), connected to a plug-board, by which any number of cells could be arranged in series or parallel, and attached to any one of three sets of terminals, conveniently placed on a working table. Fig. 1 represents a photograph of the table, showing the board in position. The storage cells were placed in the cupboard back of the distributing board. The arrangement of the plug-board with its connections is clearly indicated in Fig. 2, where the lettered and numbered squares represent brass blocks mounted on a slab of hard rubber, and the dotted lines indicate the electrical connections on the back. Provision was thus made for three students.

As this device and our present laboratory were installed at the writer's suggestion and under his direction by A. W. Schramm, of the Electrical Department of the University, it seems best, to insure accuracy and avoid uncertainty, to introduce the latter's own language in describing the two schemes:

"The brass blocks marked P are each connected to the positive terminal of a storage cell. These cells are marked in the figure by A, B, C, etc. The negative terminals are each connected to two blocks marked N, as shown. The upper line of blocks, numbered 1, are joined together, and, in fact, might be made of one strip except for economy of material. This row is attached to, and forms part of, the positive lead running to outlet No. 1 on the operating table. The negative lead for this same outlet is connected to the lower row of blocks marked 1. Thus: If the operator at outlet No. 1 wanted to use the two cells A and K in parallel it would only be necessary for him to insert plugs between the upper row of 1 blocks and the P blocks of A and K respectively, and between the N blocks of A and K, and lower row of 1's. Similarly, the upper row of blocks marked 2 are connected to the positive lead running to outlet No. 2, and the

lower row of blocks marked 2 are connected to the negative lead of the same outlet. And so on with the blocks marked 3. It will be noticed that one of the two abovementioned N blocks is located in the same row with the P blocks, and this N block of one cell is adjacent to a P block of its neighbor. This is for the purpose of connecting cells in series.

"For instance, suppose that the operator at outlet No. 2 wanted to use cells B, C and D in series, he would connect the P block of cell B to 2, the P block of C to the N of B, and the P block of D to the N block of C, finally connecting the N block of D to its adjacent 2 block.

"In addition to the above, the operator at 3 could insert plugs so as to use the cells E, F, G, H, I, J in a combination of all in parallel, three in parallel two in series, two in parallel three in series, or all in series, just as occasion might demand.

"The cells were charged (generally at night) by connecting circuit No. 1 to the 110-volt lighting circuit by means of a small knife switch, conveniently located at the side of the operating table. Incandescent lamps placed in this charging circuit kept the current down to the desired value. The cells were then all connected in series and across the No. 1 leads. Making No. 1 leads the charging circuit also provided means for using the 110-volt current for electrolytic work where the solutions were of such high resistance that the twelve cells in series were insufficient to produce the desired results. Portable resistance frames were provided, consisting of wooden frames mounted on neat iron feet, having German-silver wire coils stretched between brass blocks on both sides. There were sixteen pairs of coils of one resistance, and ten pairs of one-tenth of that resistance, all joined in series between two binding posts, and so arranged that any number of coils of either denomination could be short-circuited by means of two plugs; thus the resistance could be altered by small steps.

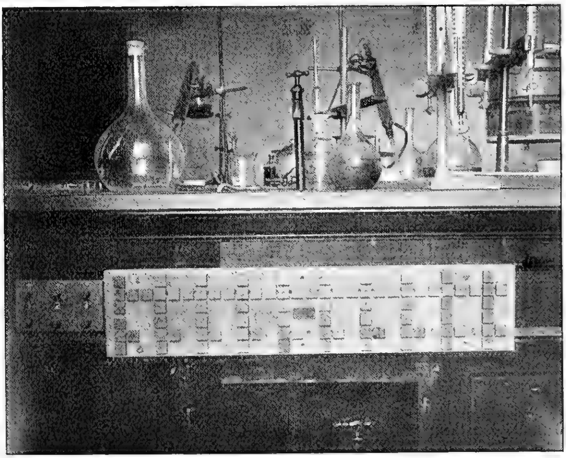


FIG. 1. Old Working Table.

A third plug was provided to prevent the necessity for opening the circuit when altering the resistance. The measuring in-

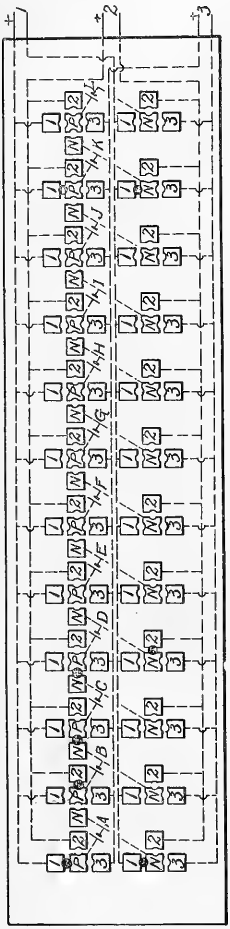

FIG. 2. Old Distributing Board.

struments were portable, Weston's and Hartman-Braun. This entire electrical equipment was fairly satisfactory and was duplicated later. It had many defects; for instance, it was possible to connect cells in parallel and series at the same time and the student sometimes preferred to make connections haphazard rather than work out and understand the whole scheme. And even though he did understand it, the chances for making a wrong connection were too great because of the confusingly large number of blocks on the boards. The resistance frames had the fault that the German-silver wire soon became so corroded as to break. Replacing the coils by tinned steel wire proved to be little or no improvement. The portable instruments, too, were in danger of being injured by solutions being spilled on them, and sometimes received rather rough handling, which soon decreased their usefulness.

"For these reasons, and the growing demand for training in electrochemistry, it was finally decided to provide a laboratory and installation sufficient to accommodate eighteen students. The effort was also made to overcome as fully as possible the defects of the previous arrangement. It will readily be seen that the matter of complication would be made indefinitely worse if the number of outlets were increased to eighteen and the number of cells to fifty, so an entirely different arrangement of switchboard had to be devised. The only room available was one fifteen feet by twenty-six feet, as shown in Fig. 3, and it soon became evident that this room would not accommodate more than sixteen students, allowing each individual three feet by twenty inches of table space.

"Storage cells were, because of their constancy, decided upon for this installation. Those in use have 120 ampère hours' capacity, with a normal discharge rate of 15 ampères and a maximum rate of 30 ampères. Two groups of twenty-four cells each were located in the compartments shown; they supply their respective sides of the room.

They are supported on racks of four shelves each, six cells per shelf. Each shelf is thoroughly paraffined and a half inch layer of ground quartz placed around the jars. two of them each controlling the six places on their respective sides of the room, and the third controlling the four places in the center. The face of one of these boards is

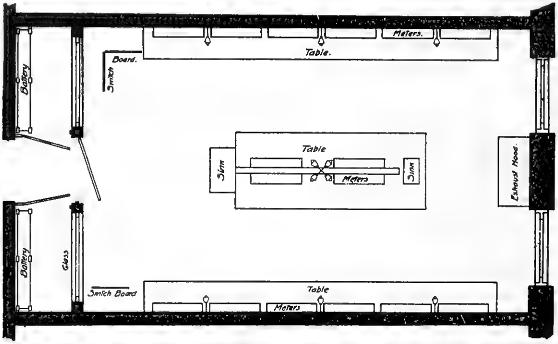

Fig. 3. Electrolytic Laboratory.

Fig. 4 shows one of these compartments with the lead wires and cut-outs for each cell.

"The switchboards are three in number, shown in Fig. 5, the letters on the face referring to the working tables controlled.

"The switchboard on the east side of the room consists of a slab of enamelled slate

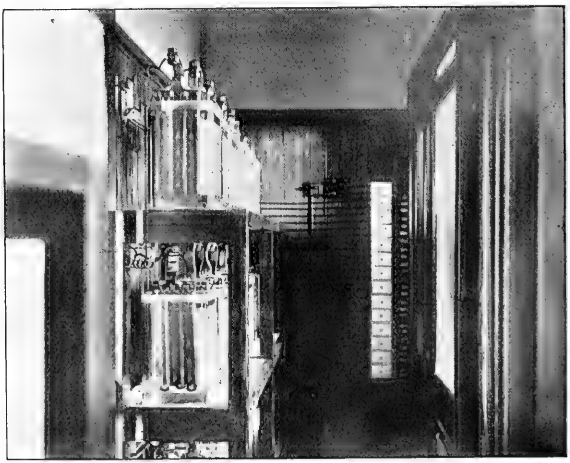

Fig. 4. Battery Room.

24 by 34 inches, one inch thick, and contains, for each of the six outlets to be controlled, one circle of twenty-five contact pieces, and has two spring levers, insulated from each other and moving about a common center, sweeping over them. The contact blocks are numbered consecutively from 0 to 24 and a stop is provided to prevent the levers from sweeping past the zero. Cell No. 1 is connected between blocks numbered 0 and 1 in each of the six circles, cell No. 2 between blocks numbered 1 and 2, and so on for the remainder of the twenty-four cells in that group, so that all blocks similarly numbered on the one board are connected together, and but a single wire leads from the six similarly numbered blocks to the junction between two cells. In this lead is provided the usual fuse. The circles are lettered A, B, C, etc., consecutively, corresponding with the letters at the outlets to be controlled.

"Should the operator at the outlet E, for instance, need two cells, he goes to this board, and finding that the cells from the twelfth cell forward are not being used in any of the circles, he places one of his levers on contact block No. 12 and the other one on No. 14. There is thus very little chance of doing anything wrong, or for persons to interfere with one another, because there is no necessity to use the same cells, and at a

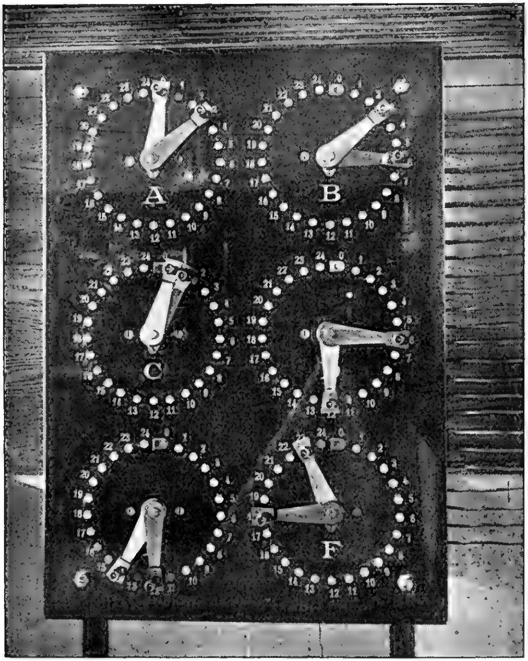

FIG. 5. Distributing Board.

glance one can observe which cells are in use. Fig. 6 shows the electrical connections from one of these distributing boards to the cells and outlets on the working tables. The levers themselves are too narrow at their outer ends to reach across from one block to another, to prevent short circuiting the cells, so they are provided with fiber extentensions on each side to prevent their falling between the blocks, and also to prevent their making contact with each other. The switchboard on the west wall is exactly similar to the one just described, it containing the circles G, H, I, K, L, and M, while the third one, which controls the four outlets on the center table, is but twenty-four charge rate of the cells exceeds the greatest estimated current needed by one operator. All brass parts on the back of the board, as well as the bared ends of the wires, are thoroughly coated with P. and B. paint, while the brass parts on the front are heavily lacquered to prevent corrosion. The surface of the contact blocks can easily be cleaned with fine sandpaper.

"The measuring instruments, after some deliberation, were chosen of the switchboard type. While this necessitated procuring at least one-third more instruments, yet the initial cost was considerably lower than if portable instruments had been provided, and experience with portable instruments leads me to believe that a greater accuracy will be attained with switchboard instruments of a good form, if not immediately, yet surely after the first six months of use.

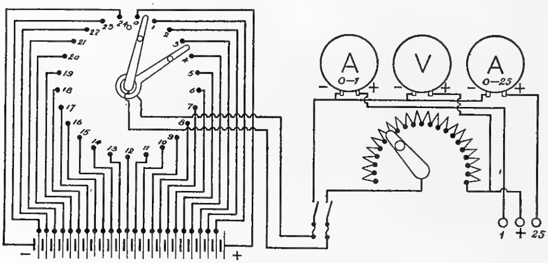

FIG. 6. Connections to Working Table.

inches square, but has twenty-six contact blocks in each circle. They are numbered 0, 24, 25, 26, and so on to 48. Between the two blocks numbered 0 and 24 are connected the cells of the group on the east side of the room; between the blocks 24 and 25 is connected cell No. 1 of the west side of the room, while cell No. 2 is connected between blocks numbered 25 and 26. This arrangement connects the two groups of cells in series, and permits the use of from one to forty-eight cells at the center table when necessity requires. It will, perhaps, have been noticed that there is no provision made for connecting cells in parallel, and this is not necessary, as the maximum dis-

"Each outlet is provided with a fused switch, a voltmeter, two ammeters, a rheostat and a terminal board. They are connected as shown in Fig. 6. The positive lead after passing through the variable resistance runs directly to the positive binding post. The wire coming from the negative binding post runs to the low reading ammeter and thence to the negative side of the switch, while the negative post marked 25 is connected to the same switch terminal,

but through the ammeter of large capacity. The anode of the electrolytic cell is therefore always connected to the middle binding post and the kathode either to the post 1 or 25, depending upon the strength of current it is intended to pass through the cell. The voltmeter, being connected as shown, measures the potential differences at the terminals of the cell, except for the addition of the small fall of potential through the ammeters.

"The voltmeters on the side of the room have scales ranging from 0 to 50, and divided to 1–2 volts. Those on the center table range from 0 to 120.

"The ammeters ranging from 0 to 1 ampère are divided to 1–100 and those reading from 0 to 25 are divided to 1–5 ampères. The three instruments are mounted side by side on an oak backboard extending the whole length of the room and are covered by an air-tight case with a glass front, as shown in Fig. 7. The cases have neither doors nor a back, but are simply screwed against a backboard with a heavy felt gasket, making the joint. The wires come out through hard rubber tubes sealed at their outer ends by insulating tape. The rheostats are of the enameled type, chosen because of their being impervious to fumes. They have a total resistance of 172 ohms, divided into 51 steps in such a way that their resistances form a geometrical progression. The first step, and the sum of all the steps, being chosen in accordance with data of the resistances of the baths determined for the work done under the old system.

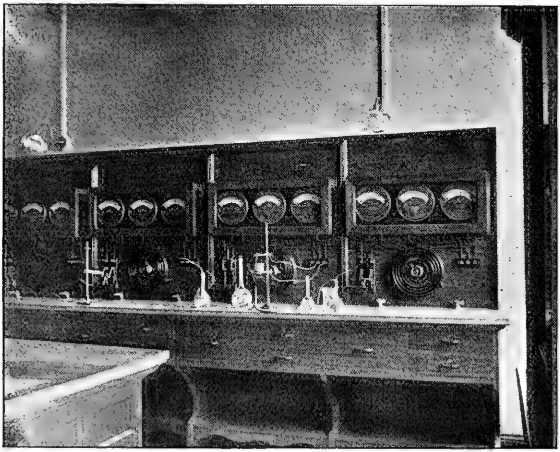

FIG. 7. Working Table.

"The wires, both those in the battery rooms and those in the laboratory proper, are covered with rubber, and those in the laboratory are further encased in oak molding, but this rather for appearance's sake than for protection. The whole installation, as well as the other fittings of the room have a very neat and finished appearance.

The problems investigated by students in

this laboratory are the study of the influence of current density and concentration upon the course of chemical reactions, the application of gas analysis to the study of the latter (in the formation of hypochlorites and chlorates), ion transference (in the electrolysis of dilute sulphuric acid or sodium hydrate) with a diaphragm, formation of persulphuric acid (influence of concentration, of current density, of temperature), metal precipitations with soluble and insoluble anodes, the introduction of aid-reactions, experiments with molten electrolytes, experiments with multipolar electrodes, the determination and separation of metals, the electrolysis of a series of organic compounds (reduction and synthesis), etc.

The writer is indebted and under many obligations for this installation to Provost Harrison who provided the necessary funds.

In conclusion it may be said that in a second room close by there is also provision for work at high temperatures. A Moissan and two Borscher's furnaces are used for this purpose. They are in direct connection with a 50-horse-power dynamo and are furnished with satisfactory resistance and measuring instruments. They are applied in the reduction of oxides, in the electrolysis of fixed salts, the production of alloys, etc.

The two laboratories afford all that is essential to acquaint the student with the fundamentals of electrochemistry, and give him also ample facilities for research in this domain of chemical science.

Edgar F. Smith.

LEGISLATIVE RECOGNITION OF SCIENTIFIC WORK.

It is not often that Science has the opportunity of chronicling an event such as happened at Madison, Wis., on March 27th, when the Legislature of the State in open session presented to Dr. S. M. Babcock, of the University of Wisconsin, a beautiful

bronze medal 'recognizing the great value to the people of this State and the whole world' of his inventions and discoveries, 'and his unselfish dedication of these inventions to the public service.'

Governments such as ours are not prone to recognize deeds of scientific men, but the service rendered in this connection was of such value that the State has honored itself by paying honor to the man who refused to take out a patent on his invention, but gave it freely and willingly to the people.

Dr. Babcock's discoveries in the field of agricultural science have been many,

but the development of his system of rapidly determining the amount of butter fat in milk has practically revolutionized the dairy industry. It saved the system of factory dairying from destruction by giving a method for the equitable division of moneys earned, and its rapid extension into all dairy countries of the world has contributed much to the renown of American science in other parts of the earth.

The recognition of Dr. Babcock's services by the State of Wisconsin is not confined to such narrow geographical limits. Although not an exhibitor, last year he was awarded the Grand Prix d'Honneur at the Paris Exposition. Recently the dairymen of New Zealand have sent him a beautiful testimonial in the shape of an elegantly bound hand-painted album of New Zealand scenery.

Dr. Babcock's fame as an inventor rests largely upon his milk test, but to men of science, who are familiar with dairy and agricultural investigations, his many discoveries in these fields are regarded as even more brilliant and of more value to science than the invention for which he is now honored.

SPRING MEETING OF THE COUNCIL OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE spring meeting of the Council was held in the Assembly Hall of the Cosmos Club on the afternoon of April 17, 1901. There was a larger attendance of members than is usual at the spring meeting.

The permanent secretary presented a report upon the operations of his office since the midwinter meeting of the Council, including with this a report of the committee appointed at the midwinter meeting and empowered to act upon the applications for membership received in the interim between the midwinter and spring meetings. The report of the committee was very encouraging. It seems that by means of letters signed by the president and the permanent secretary, and addressed to teachers of science in the universities and collegiate institutions of the country, a large number of new members has been added to the rolls of the Association. Further, local committees have been formed at several hundred points in the United States, and empowered by the president and permanent secretary to make an effort to increase the number of members in their several localities. As a result of this work 540 new members have been elected since last Christmas, a number of these being very prominent men of science, who, although formerly members of the Association, had for one reason or another allowed the membership to lapse.

The general condition of the Association was reported to be admirable. In point of number of members the high-water mark was reached in 1891 at the Washington meeting, when there were 2,054 members on the rolls of the Association. At the present time the actual membership of the Association paid up to January 1, 1901, is in the neighborhood of 2,350 while about 100 additional members have been recently elected, but have not yet completed membership.

The permanent secretary further reported that the arrangement with the journal SCIENCE is apparently giving perfect satisfaction and is greatly helping the Association in many ways.

The arrangements for the Denver meeting were reported to be progressing favorably. Local committees in Denver are organizing and a railroad rate of one fare plus two dollars west of Chicago has already been gained. No definite conclusions have been reached by the passenger associations east of Chicago, but it is expected that the details will be settled and that the preliminary announcement concerning the meeting will

be issued to all members of the Association by the middle of May.

The permanent secretary presented his financial statement for the year ending December 31, 1900, which showed receipts amounting to $12,321.60, and expenditures, including $1,300 transferred to the treasurer, amounting to $7,579.84, leaving a balance to new account of $4,741.76. Some unusual expenditures were mentioned in this account, especially the expenses of the New York meeting, which were borne by the Association instead of by the local committee as at previous meetings, and the storage on back volumes and the expense of their removal to New York, where they are now stored free of charge to the Association in the Library of Columbia University. The account, having been properly audited, was accepted by the Council and ordered printed in the next volume of *Proceedings*.

Changes in their personal plans for the summer having necessitated the resignations of Professor Lord, Secretary of Section A; Dr. Reed, Secretary of Section B; Mr. Penrose, Secretary of Section E; and Miss Benneson, Secretary of Section I, their resignations were accepted. Dr. G. A. Miller was elected to fill the vacancy as secretary of Section A, and provision was made for the temporary filling of the other vacancies by committees.

Dr. C. S. Minot presented a report on behalf of the committee appointed to consider the plan of securing a convocation week immediately after the Christmas holidays. The Association of Universities, consisting of the fourteen leading American universities, passed unanimously a resolution recommending that a week be set aside for the meeting of scientific and learned societies, and steps are now being taken to secure from the universities an agreement not to hold their sessions during the week in which the 1st of January occurs.

Dr. Thomas Wilson made a report of progress on behalf of the committee on the protection and preservation of objects of archeological interest, showing that a bill had been carefully drafted and had nearly passed Congress last session, being laid aside only on account of urgent legislation.

The permanent secretary was instructed to take up the matter of the preparation of an index to the first fifty volumes of the *Proceedings* and to take such preliminary steps as he might deem advisable, and report in full at the Denver meeting.

SCIENTIFIC BOOKS.

Gli Insetti Nocivi. By Dr. A. Lunardoni and Dr. G. Leonardi. Naples. 4 vols. 1889–1901.

Since our knowledge of European economic entomology has largely been drawn from books descriptive of the injurious insects of middle Europe, it is a distinct pleasure to have before us for reference a large and valuable work on the injurious insects of a part of southern Europe—the Italian region. This work is, however, more than a compendium of the noxious insects of Italy; it is, practically, a text-book of Italian entomology with detailed accounts of injurious species. Volumes I. and II., dealing with the general subject, Coleoptera and Lepidoptera, are by Dr. Lunardoni; Volumes III. and IV., dealing with the remaining orders, are by Dr. Leonardi. Volume I. contains 570 pages; Volume II., 287 pages; Volume III., 549 pages; and Volume IV., 862 pages.

In the general subject are included directions for the control of noxious insects. Of special interest in the part on Coleoptera is a table for the determination of the species of *Scolytini* according to the nature of their galleries. In the second volume, dealing with the Lepidoptera, the chapters treating of the Tortricidæ and Tineidæ are very full. The discussion of remedies for species in these two families is of considerable value to American workers, since many of these moths are injuriously abundant in the United States.

In the third and fourth volumes the figures are more numerous and the bibliographic lists

more complete, but unfortunately the typographical errors are rather annoying. The Hymenoptera occupy 170 pages of Volume III, the larger part of which treats of the gallflies and sawflies. The Diptera occupy the remainder of Volume III., and are treated at more length than the preceding orders. The fleas occupy the position of a family at the end of the order. Several Trypetidæ, especially *Dacus oleæ*, *Ceratitis hispanica* and *Rhagoletis cerasi* are treated in much detail. The Hessian fly, which appears under the unfamiliar generic name of *Mayetiola*, occupies fourteen pages.

In the fourth volume the Neuroptera are passed over rather hastily. The Pseudoneuroptera are included under the Orthoptera. The Hemiptera receive the fullest treatment of all. Over 180 pages are occupied with the Aphidæ, and 200 with the Coccidæ. *Phylloxera* covers 75 pages. Nearly all the Coccidæ are figured. Under the name of *Aonidiella perniciosus*, a long account is given of the San Jose scale. In the Orthoptera considerable space is devoted to the remedies for grasshoppers; spraying machines and catching machines, drawn by two men, seem to be especially favored. The volume concludes with a brief notice of the Thysanura under the ordinal name of Pseudoinsecta.

NATHAN BANKS.

An Introduction to Modern Scientific Chemistry, in the form of popular Lectures suited for University Extension students and general readers. By Professor LASSAR-COHN, Ph.D., University of Königsberg. Translated from the Second Edition by M. M. PATTISON MUIR, M.A., Cambridge. New York, D. Van Nostrand Company. Pp. viii + 348. Price, $2.00.

The author's preface says: "In this introduction to *Modern Scientific Chemistry* an attempt is made to give a succinct and accurate presentation of chemistry on strictly scientific lines, and at the same time in as popular a form as is compatible with the vast range of the subject. The book can be followed easily by any one who takes a serious interest in natural science, and will not, I hope, be unwelcome to the younger chemists who are still pursuing their studies. A teacher of chemistry who may not have paid special attention to the methods of presenting his subject will perhaps find in the book something useful to himself and helpful to his hearers."

A careful examination of the text impresses one with the idea that the author has made a particularly happy use of the word modern in his title; and that the promises of the preface have been abundantly fulfilled. The author has been eminently successful in solving the difficult problem of giving the theories and facts of chemistry in a form not only popular but exact. The keynote of the book is its emphasis of the fundamental conceptions of the science.

The style is clear, convincing and always interesting. While the book is intended primarily for University Extension students and general readers, to the student and younger teachers of chemistry it offers a wealth of valuable, accurate information, especially concerning the chemical principles involved in the manufactures of illuminating gas, smokeless powders and other explosives, fertilizers, matches, glass, aluminium, etc.

The reader who does not find this book helpful and inspiring must be very well informed in scientific chemical subjects.

The translation is excellent, and will serve to introduce Professor Lassar-Cohn's work to a new world of readers.

The crudeness of the illustrations (by the author) is the only unsatisfactory feature of a book of rare merit.

WILLIAM B. SCHOBER.

LEHIGH UNIVERSITY.

An Elementary Treatise on Qualitative Chemical Analysis. By J. F. SELLERS, Professor of Chemistry, Mercer University, Georgia. Boston, Ginn & Company. 1900. Pp. ix + 160.

The author has attempted in this treatise to place qualitative analysis upon a scientific basis, to do for this subject what Ostwald has done for analytical chemistry in general. It is very evident from the nature and arrangement of that part of the book devoted to the theory of solutions that it is a reflection of Ostwald's 'Foundations of Analytical Chemistry.' As such it is to be commended. The book, how-

ever, is evidently intended for a younger class of students than Ostwald intended his work. The author has so condensed the subject, and has attempted to cover so much ground, that it is believed it will be difficult for the student to grasp the real significance of the subject. It would have been a much more valuable book if the theory of solutions had been presented more simply, perhaps at some greater length, and with more numerous discussion of examples.

Some of the statements will, undoubtedly, give the student a false impression. On pages 19 and 21 it is stated that the amount of dissociation is increased by heat, giving the impression that this is a general law. Again, on page 21 one gets the idea that the greater the dilution the greater is the chemical activity. The explanation of the effect of a salt of a weak acid on the strength of a strong acid is merely a statement of fact.

That portion of the book, pages 27–157, devoted to the processes of qualitative analysis is well arranged, practical and progressive, including all the more recent and approved methods of separation. Considerable stress is laid upon spectroscopic analysis. The application of normal solutions to laboratory reagents is to be commended.
H. F.

Laboratory Instructions in General Chemistry. By ERNEST A. CONGDON, Professor of Chemistry, Drexel Institute. Philadelphia, P. Blakiston's Son & Co. 1901. Pp. viii + 110.

It is difficult to review justly a laboratory book of experimental chemistry which is primarily intended for the author's own students, because there is no means of knowing what instruction the student has received from the lectures which accompany the laboratory course. When, however, it is stated that the book can be used with any standard text-book, the reviewer's task becomes much simpler, since the laboratory guide is supposed to follow somewhat closely the text of the standard work.

The first 21 pages of this book are devoted to experiments illustrating principally the laws of physical and chemical changes, and chemical reactions. These experiments, if the student is expected to follow them in order, are poorly selected and badly arranged. Indeed many of them are entirely out of place. Some of the experiments involve the use of substances, the properties of which must be entirely unknown, and it would be impossible to explain at so early a stage the nature of the reactions taking place. The student is asked, on his second or third day in the laboratory, to try the following experiments: the action of sulphuric acid on a mixture of potassium chlorate and sugar, the preparation of gunpowder, and red and green fires. These experiments undoubtedly do represent physical and chemical changes, but perhaps too violently for a beginner. Under the chapter on reactions, the student is asked to write the reactions between ferric chloride and ammonia, and ammonium sulphocyanide, ferric hydroxide and hydrochloric acid. All this before oxygen has been studied!

Beginning with oxygen, however, the experiments are the standard experiments to illustrate the properties of the various elements.

An appendix of fifteen pages contains quantitative experiments to illustrate the laws of definite and multiple proportions and the various gas laws. It is believed that some of them are too difficult for first-year students in chemistry.
H. F.

The Chemists' Pocket Manual. A Practical hand-book containing tables, formulas, calculations, physical and analytical methods for the use of chemists, assayers, metallurgists, manufacturers and students. By R. K. MEADE, B. S., Instructor in Chemistry in Lafayette College, Easton, Penn. Easton, Penn., The Chemical Publishing Co. Price, $2.00.

The nature and general contents of this book are described in the title. The book is well printed and contains such information as a chemist is almost daily in need of, and can be highly recommended as a reference book. The only feature of the book about which anything else than praise can be expressed is the price at which it is sold. The book is about 4 x 6 inches and contains 193 pages. The 'Chemiker Kalender,' the general nature of which this book follows, with its supplement, contains about three times the amount of material found in this book and only costs one half as much.
J. E. G.

BOOKS RECEIVED.

Le système métrique des poids et mesures. G. BIGOURDAN. Paris, Gauthier Villars. 1901. Pp. vi + 458. 10 fr.

SCIENTIFIC JOURNALS AND ARTICLES.

THE *Botanical Gazette* for April contains further descriptions of new species of North American trees by Professor C. S. Sargent. Among them are thirteen species of *Crataegus*, which is proving to be one of the most prolific of our genera in species, a new *Betula* from Alaska, and a new *Cupressus* from California. Professor C. O. Townsend writes upon the effect of hydrocyanic acid gas upon grains and seeds. Since this gas has become extensively used for fumigating purposes, it has become important to determine its effect upon the germination of seeds and upon their use as food. Professor Townsend has demonstrated that if the grain and seeds are dry the influence of the gas upon the vitality is far less marked than if they are moist. Dry seeds treated with the gas are not injured for food, but damp seeds should not be used until several hours after removal from the gas. Mr. A. C. Life contributes an interesting study upon the tuber-like rootlets of *Cycas revoluta*, in which the rôle played by the fungi and by the algae upon the formation of these tubercles is worked out. Mr. Newton B. Pierce describes a new bacteriosis of the walnut which has become a well-marked disease in California. The active organism proves to be a new species of *Pseudomonas*. The usual book reviews, minor notices and notes for students complete the number.

THE second (April) number of Volume II. of the *Transactions* of the American Mathematical Society contains the following papers: 'Canonical Forms of Quaternary Abelian Substitutions in an Arbitrary Galois Field,' by L. E. Dickson; 'Certain Cases in which the Vanishing of the Wronskian is a Sufficient Condition for Linear Dependence,' by M. Bôcher; 'An Elementary Proof of a Theorem of Sturm,' by M. Bôcher; 'On the Determination of Surfaces capable of Conformal Representation upon a Plane in such a Manner that Geodetic Lines are represented by Algebraic Curves,' by H. F. Stecker; 'On the Existence of a Minimum of Integral $\int_{x_0}^{x_1} F(x, y, y')\,dx$ when x_0 and x_1 are Conjugate Points, and the Geodesics on an Ellipsoid of Revolution; a Revision of a Theorem of Kneser's,' by W. F. Osgood; 'On the Geometry of Planes in a Parabolic Space of Four Dimensions,' by I. Stringham.

THE March number of the *Bulletin* of the American Mathematical Society contains the following papers: 'Report of the December Meeting of the Chicago Section,' by Professor T. F. Holgate; 'Indirect Circular Transformations and Mixed Groups,' by Professor H. B. Newson; 'Pure Mathematics for Engineering Students,' by Professor A. S. Hathaway; 'Review of Adams' Unpublished Papers,' by Professor E. W. Brown; 'Notice sur M. Hermite' (translation of an address before the Paris Academy of Sciences), by M. C. Jordan; 'Notes'; 'New Publications.' The April number contains the following papers: 'Report of the February Meeting of the Society,' by Professor F. N. Cole; 'Green's Functions in Space of One Dimension,' by Professor M. Bôcher; 'On a System of Plane Curves having Factorable Parallels,' by Dr. Virgil Snyder; 'Possible

Triply Asymptotic Systems of Surfaces,' by Dr. L. P. Eisenhart; 'Note on Hamilton's Determination of Irrational Numbers,' by Dr. H. E. Hawkes; 'Review of Muth's Elementartheiler,' by Mr. T. J. I'A. Bromwich; 'Shorter Notices': 'Fricke's Lectures on Higher Mathematics,' and 'Böger's Plane Geometry of Position,' by Professor H. S. White; 'Notes'; 'New Publications.'

SOCIETIES AND ACADEMIES.

SECTION OF GEOLOGY AND MINERALOGY OF THE NEW YORK ACADEMY OF SCIENCES.

AT the meeting of the Section on March 18th, the following program was presented:

'The Cambro-Ordovician Outlier at Wellstown, Hamilton County, New York.' In introducing the subject of the paper Professor Kemp gave a brief account of the physiographic problems presented in the Adirondacks and of the significance of the smaller outlines of Paleozoic strata which occur within the crystalline area. He then discussed the Wellstown exposure and described it in much the same way as he has already done in print in the 'Eighteenth Annual Report of the State Geologist of New York,' page 145. The general conclusion favored the existence of land areas of ancient crystalline rocks in the vicinity of Wells, and, it seemed to the speaker, that the peculiar sediments could not be explained in any other way. Pebbles, as large as one's fist, of gneiss similar to that found in the ancient hills, are imbedded in the Trenton limestone, and much sand is found in the limestones of both the Calciferous and the Trenton. It was admitted that the present valley is due to faulting, as has been previously claimed by Dr. R. Ruedemann, but the shores of the late Cambrian and early Ordovician could not have been far from the present outcrops of the Paleozoics at Wells. Mr. Van Ingen and Doctors Levison, Dodge, White and Julien took part in the discussion of the paper.

Dr. Julien remarked, in regard to the sand found in the limestones to which Professor Kemp referred, that although the smaller and angular portion of the sand, in which feldspar is common, and particles of garnet, epidote and menaccanite also occur, may possibly be residual, derived from decay of gneiss adjacent to the shores of the ancient basin, the predominant quartz grains, well rounded and even perfectly spherical, could not possibly be of that origin. Their sculpture indicates prolonged action during ages before they assumed spherical form, and that although found in sediments loose or consolidated in all periods from the quartzites of the Laurentian down to the present beaches along rivers, lakes and ocean, they represent in all cases ancient materials which have been worked up over and over again from period to period. In the Potsdam of the North American continent they have been accumulated in an extensive outer-beach deposit, the result of an enormous resorting of materials throughout the vast Cambrian time. These 'paleospheres' were doubtless derived from the same Potsdam horizon which has yielded the oolitic quartz sand of the 'singing beach' on the shores of Lake Champlain, near Plattsburg, not many miles from the Wellstown Ordovician outcrop. They certainly were not swept into this limestone basin by currents, since the absence of sorting and the parallel deposition of their axes show that they were dropped down from the surface in a continuous gentle shower. The conditions which favored this consist of the floating of sand from the beaches along sheltered bays, such as Long Island sound, on every quietly rising tide, with its seaward transport, often to hundreds of miles off the coast, commonly caught in the dredges of surveying steamers, as noted by Verrill and others, and in its constant subsidence over the bottom. Such sand transport was plainly in progress over the quiet embayment occupied by this limestone, from surrounding beaches supplied from the decay and disintegration of an ancient shore of Potsdam and Calciferous sandstones. The various sands referred to in these remarks were illustrated by photomicrographs.

'A Method of facilitating Photography of Fossils' was described by Mr. Gilbert Van Ingen. The process consists in forming, on the surface of the specimen to be photographed, a thin coating of ammonium chloride by the combination near that surface of ammonia gas and

hydrochloric acid gas. Such a coat effectually hides all coloration of the specimen and reflected light, and does not obliterate the finer details of the sculpture. The salt is perfectly harmless and may be readily removed by water, or by a soft brush. The paper was discussed by Professors Stevenson and Kemp, and Drs. Levison, Julien and White.

THEODORE G. WHITE,
Secretary.

THE NEW YORK SECTION OF THE AMERICAN CHEMICAL SOCIETY.

THE regular meeting of the New York Section of the American Chemical Society was held on Friday evening, April 5th, at the Chemists' Club, 108 West Fifty-fifth street, and over fifty members were present.

The following papers were read:

F. A. Sieker—'The Detection of Methyl Alcohol.'

A. H. Gotthelf—'The Synthesis of Alkyl Ketodihydroquinazolins from Anthranilic Acid.'

Durand Woodman—'Note on the Determination of Moisture in Coal.'

E. F. Kern—'Comparison of Methods for the Electrolytic Precipitation of Iron.'

E. F. Kern—'The Electrolytic Precipitation of Nickel and Cobalt from a double Cyanide Solution.'

In the discussion of Mr. Sieker's paper, Dr. Eccles suggested that for a method of detecting methyl alcohol depending on the production of a specific odor, he thought that which produced methyl salicylate was to be preferred as more characteristic than the one described producing formaldehyd.

Dr. Woodman's paper was an effort to ascertain more clearly the effect of oxidation in drying samples of coal according to the accepted method for determination of moisture. It appeared that the apparent loss of moisture in a stream of dry carbonic acid gas was uniformly less than when the coal was heated in contact with the air. This indicates that by the ordinary method there is a loss by oxidation in the first stages of heating, before the well-known increase of weight begins by more prolonged heating. The paper evoked considerable discussion as to whether the secondary increase of weight was due to oxidation, occlusion or to some change not yet explained. It was stated that further work was in progress with a view to clearing up some of these points.

Mr. Kern gave a very full and valuable exposition of the electrolytic methods for precipitation of iron, nickel and cobalt.

After the transaction of some miscellaneous business in connection with the twenty-fifth anniversary of the Society, the meeting was adjourned to May 10th.

DURAND WOODMAN,
Secretary.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 338th meeting was held on Saturday evening, April 6th, and was devoted to an address by Erwin F. Smith, on the subject of 'Bacterial Diseases of Plants,' the speaker considering in detail diseases of the cucurbits, the cabbage and the tomato, illustrating his remarks by numerous slides. These showed the entire plants and their histological structure in health and under the effects of the diseases discussed, showing in certain cases the water canals crowded with bacteria and in others the breaking down of the cell walls and the invasion of the healthy tissue by bacteria. The speaker described the physiological differences between the species treated and said that the diseases considered were mostly conveyed from plant to plant by beetles whose bites inoculated the healthy plants with bacteria derived from the diseased plants on which they had previously fed. Hence the remedy for the disease was to wage war on the beetles.

F. A. LUCAS.

THE LAS VEGAS SCIENCE CLUB.

THE regular monthly meeting of the Club was held April 9th. Mr. T. D. A. Cockerell exhibited specimens of *Sphærium magnum* Sterki MS., found abundantly in the Pleistocene deposit of the Arroyo Pecos, Las Vegas. This species, although undescribed, was known to Dr. Sterki in the living state from Missouri, Kansas, etc.; but it had not been observed living in New Mexico. Mr. Cockerell also exhibited *Veronicella agassizi* n. sp., a slug found by Professor Alexander Agassiz in Tahiti. It was related to *V. gilsoni* of the Fiji Islands but apparently distinct. Mr. Emerson Atkins read a paper on

the 'Occurrence of the Western Evening Grosbeak (*Coccothraustes vespertinus montanus*) in Las Vegas,' and exhibited specimens of the birds. These birds had never been seen in Las Vegas, until about October 30th last, when they suddenly appeared in great numbers. They had remained in the town until the present month; Mr. R. H. Powell remarked that he had seen them as recently as April 7th. Mr. Frank Springer stated that he had observed them in Santa Fé during February. Mr. E. L. Hewett exhibited a curiously twisted stone spear-head which had been found at Chapelle, N. M. It was evidently designed to twist in the wound, and was unique among the spear-heads collected in New Mexico. Mr. Hewett also called attention to a triskelion (three-leg) design which he had seen on a piece of ancient pottery from Arizona. He also showed some of the vessels from the burial mounds of the Pajarito district, N. M., in which the same design occurred, but modified, so that what appeared to be hands, with claw-like fingers, took the place of feet.

T. D. A. C.

DISCUSSION AND CORRESPONDENCE.

PRIORITY OF PLACE AND THE METHOD OF TYPES.

In Science for April 12, 1901, Professor N. L. Britton has given an adequate explanation and justification for the rule of nomenclature which accepts precedence of page or position as a substitute for priority in time in determining which of two or more simultaneously published synonyms shall receive permanent recognition. It is further held that the proposed use of the first species as the type of its genus is simply an extreme extension of the idea of priority of place, and all reference to the method of types as a means of securing stability in the application of generic names is omitted.

In reality the priority or precedence analogy of the method of types is quite incidental to the main argument, and has been brought forward only because it seemed likely to influence favorably those who have been zealous in advocating 'page priority.' Professor Britton very properly maintains that there is an important logical distinction between the two propositions, but he does not bring out the facts that while precedence priority is a small matter, affecting a few isolated instances, stability in the use of generic names is of universal taxonomic importance, and that the method of types * still remains the only suggested means of obtaining it. Page priority is not particularly just or reasonable, since an author's last treatment of a genus or species is likely, on the whole, to be better than the first, and a rule to take the last of the synonyms appearing in the same book would be quite as definite and as readily applicable as one requiring the use of the first. But such a policy would not be in accord with the principle of priority, and it accordingly received but little consideration when the formulation of a definite rule was undertaken. With the method of types, also, the desideratum is a uniform rule, but thus far those who object to the use of the first species have not proposed to use the last species, or any other species in particular, doubtless because they still fail to realize the taxonomic bearing of the fact that under an evolutionary view of nature a genus is no longer to be treated as a concept † or a definition, but as a group of species.

The reasons for selecting the first species as the nomenclatorial type of a genus are quite as good, to say the least, as those for accepting the first name in a book, but they appear trivial when compared with those which require the taking of *some* species as the type, and that by a definite rule of uniform application. Accordingly, it is scarcely pertinent to bring merely nomenclatorial or historical objections against the proposition to use the first species as the type, until it can be shown that the general systematic and taxonomic requirements met by the method of types can be accommodated by the use of some other than the first species.

Professor Britton's further objection to the use of the first species, that 'it would render useless for nomenclatorial purposes much original investigation through which genera have been definitely established,' must be seriously discounted, to say the least, in view of the fact that the 'original investigation' has been conducted, either without any uniform plan, or

* Science, September 28, 1900, XI., 476.

† Science, October 14, 1898, VIII., 513.

under one incapable of producing the desired uniformity. If we may trust President Jordan's frank statement of the results of his extensive experience with the method advocated by Professor Britton, "The process of elimination has never been consistently followed, nor can the process be so defined that it can yield fixed results in the case of the complex genera of the last century."*

Instead of supplying an argument for continuing longer on the same lines, the variety and instability inevitable under the method of elimination afford an excellent reason for seeking a more satisfactory rule of procedure. And to obtain this it is not, as Professor Britton seems to imply, necessary that 'historical types' or the expressed wishes of the authors of genera shall be disregarded. Those who are interested in the possibility of such improvements should, however, consider the several steps in the order of their importance and cease to make confusion between the taxonomic principles and the merely nomenclatorial incidents of the process.

The first essential of systematic biology is a convenient and stable taxonomy.

A satisfactory degree of convenience was attained over a century ago by the adoption of the binomial system, involving the joint recognition of generic and specific names.

Stability can be secured by the uniform use of the oldest names applied under the binomial system of nomenclature.

Generic and specific names have nomenclatorial standing when they have been used as parts of binomials.

Priority requires that a species shall bear the oldest name applied to it, and, conversely, that a specific name shall be used only for the first species to which it was applied.

Effective priority or stability in the application of a generic name can be attained by restricting its use to the congeners of the first species to which it was applied as part of a binomial.

All such principles and methods have, however, their logical and practical limitations and exceptions, but it is quite illogical and unpractical to ignore or set aside a more important for

* SCIENCE, November 23, 1900, XII., 786.

a less important consideration. It is essential that we have some one species permanently designated as the nomenclatorial type of each genus, but it is not essential that it be the first species, and there are good reasons for admitting two exceptions, not of the method of types, but of this suggestion for its nomenclatorial application.

Exception 1.—Describers of genera may designate their type species in the papers in which their generic names are published.

Exception 2.—Generic names adopted into binomial nomenclature from older writings should be used in their original application. It is not, however, desirable or expedient that such restorations be carried in botanical literature farther back than Tournefort's 'Institutiones' (1700).

The first provision enables us to conserve such parts of systematic literature as can be readily adjusted to present ideals and methods, while the second avoids too abrupt a break between the binomial and the prebinomial literature of botany, and at the same time obviates the principal objection to 1753 as the initial date for botanical nomenclature.

Until an equally practicable alternative proposition is brought forward, the use of the first species as generic type should receive the support due to the idea of stability in biological taxonomy, whether the above exceptions be admitted or not. The exceptions do not, however, militate in any sense against the principles involved, and will but slightly increase the labor of applying the method of types. It is accordingly to be hoped that they will be deemed a sufficient concession by those who have approached biological studies from the traditional and historical standpoints, but who are still able to realize the difference between a rule of nomenclature and a primary requisite of biological taxonomy.

O. F. COOK.

WASHINGTON, D. C., April 15, 1901.

THE PROPER NAME OF THE ALPINE CHOUGH.

TO THE EDITOR OF SCIENCE: My suggestion in a recent number of SCIENCE (N. S. Vol. XIII., p. 232) that the name of the alpine chough should stand as *Monedula pyrrhocorax* L. (Hass),

in view of Hasselquist's use of the name in 1762, for the *Upupa pyrrhocorax* Linné (1758), which latter name was changed to *Corvus pyrrhocorax* by Linné in 1766, Hasselquist's name therefore having priority over the latter one by four years. Hasselquist's name having appeared first in 1757, and later in a German translation of his work,* Mr. P. S. Sclater (SCIENCE, N. S. Vol. XIII., p. 626) thinks the name should not stand, as it was first described prior to 1758, and after that date only in a translation of Hasselquist's work. If Mr. Sclater's view be adopted, will it not be necessary to exclude many names occurring in the 10th and 12th editions of the *Systema Naturæ*, because they were originally described in earlier editions of that work?

Whether the alpine chough occurs in 'Lower Egypt' or not has in my opinion little bearing on the matter. The question is, is *Monedula pyrrhocorax* Hass, the same as *Upupa* (=*Corvus*) *pyrrhocorax* Linné; and we have Linné, who personally examined Hasselquist's collections, as an authority in the affirmative.

WILLIAM J. FOX.
THE ACADEMY OF NATURAL SCIENCES,
PHILADELPHIA, PA.

* 'Iter Palæstinum,' etc., 1762.

BOTANICAL NOTES.

THE STUDY OF MOSSES.

DR. A. J. GROUT, of the Brooklyn Boys' High School, has made the study of mosses much easier by the publication of a very pretty little book, entitled 'Mosses with a Hand-Lens,' and two sets of dried and carefully prepared specimens under the titles of 'North American Musci Pleurocarpi' and 'Hand-lens Mosses.' The book is a thin octavo volume of about seventy-five pages, and is a non-technical handbook of the more common and more easily recognized mosses of the Northeastern United States. It is illustrated by helpful figures, which, if not as smoothly engraved as some to be found in recent text-books, have the merit of clearly showing what they are intended to show. The descriptions are, as indicated above, non-technical, but they will perhaps prove all the more helpful to most beginners on that account. In all, one hundred species are noticed. The volume closes with an appropriate glossary of bryological terms and a brief index. The first collection of specimens will enable the beginner to recognize the genera and species represented, although this was not the use which Dr. Grout had in mind in their preparation. They were designed rather for the benefit of the professional bryologist, but they will serve the beginner as well, since they illustrate the plants and their fruits. The second collection, which is just now appearing, was evidently suggested by the use here indicated. It consists of similar specimens, carefully selected and supplied with neat printed labels.

BOTANICAL FACILITIES AFFORDED TO STUDENTS BY THE NEW YORK BOTANICAL GARDEN.

IT is probably not generally known to what extent the rich treasures of the New York Botanical Garden are available to students of the several phases of botany. Although the institution is in the first lustrum of its existence, it inherited the collections of books and specimens left by Dr. Torrey after a long life of accumulative activity. There are thus nearly one million specimens in the herbarium and about nine thousand volumes in the library. Added to these are the native plants growing in the woodlands, meadows and swamps of the two hundred and fifty acres of land constituting the domain of the Garden, supplemented by the plantations of herbaceous and woody vegetation, and the already large collections under glass in the great Plant House. The laboratories, of which there are physiological, embryological, chemical, morphological and taxonomic, are housed in the fine building known as the 'Museum Building.' They occupy a suite of fourteen rooms on the upper floor of the building, and are admirably planned for the several lines of work to be done in them. From a recent statement by the director we learn that opportunities are afforded for work in the following subjects: Physiology of the cell, ecology, morphology of algae, morphology of fungi, morphology of bryophyta, morphology of pteridophyta, morphology of spermatophyta, experimental morphology, taxonomy of algae, tax-

onomy of fungi, taxonomy of bryophyta, taxonomy of pteridophyta, taxonomy of spermatophyta, taxonomy of gramineae, embryology of spermatophyta, special taxonomy, regional botany, physiology of nutrition, ecological physiology, physiological anatomy, general physiology. The director says further, "Almost any problem in botany may be taken up by the trained botanist, who may come to the laboratories with the expectation of finding facilities for his work." It should be borne in mind that 'the laboratories never close for a vacation,' and that one may work here when most universities are closed.

A STUDY OF WHEAT.

MR. M. A. CARLTON, of the Division of Vegetable Physiology and Pathology of the United States Department of Agriculture, has for several years been engaged in a study of wheat with especial reference to its growth in different portions of this country. He finds that the country may be divided into eight wheat districts, as follows: (1) The soft wheat district, including mainly the north Atlantic states (in Virginia the mountainous region only); (2) the semi-hard winter wheat district, including the north central states; (3) the southern wheat district, including the northern part of the southern states; (4) the hard spring wheat district, including the states of the northern Plains; (5) the hard winter wheat district, including the states of the middle Plains; (6) the durum wheat district including a part of the states of the southern Plains; (7) the irrigated wheat district, in scattered areas in the Rocky Mountains and the Great Basin; (8) the white wheat district, including the larger part of the Pacific Coast states. A colored map illustrates these divisions in the bulletin (No. 24) in which Mr. Carlton discusses this subject. The species and sub-species of wheat recognized by Mr. Carlton are in the main those accepted by Koernicke and Werner in their 'Handbuch des Getreidebaues' as follows:

Triticum vulgare, the most valuable and widely distributed species, represented by a greater number of varieties than all other species taken together, including the soft winter wheats, hard winter wheats, hard spring wheats, white wheats and early wheats:

Triticum compactum, more properly a variety of the former, including the club sheets.

Triticum turgidum, a subspecies of *T. vulgare*, including the Poulard wheats, with such varieties as 'Seven-headed Wonder,' 'Hundred-fold' and 'Miracle.'

Triticum durum, a subspecies of *T. vulgare*, including the durum or macaroni wheats.

Triticum polonicum, a distinct species, including the Polish wheats.

Triticum spelta, a subspecies of *T. vulgare*, including spelt.

Triticum dicoccum, a subspecies of *T. vulgare*, including spelt-like wheats bearing the German name of 'Emmer.'

Triticum monococcum, a very distinct species, practically unknown in America, and but little grown in Europe, where it bears the German name of 'Einkorn.' It is said to be 'rust proof.'

In discussing the problem of the best varieties for this country the author says that, "considering all qualities, the best wheats in the world are of Russian origin, coming particularly from eastern and southern Russia. They are resistant to cold and drought, and are more or less resistant to leaf rust, and have the best quality of grain." Considerable space is given in the bulletin to the discussion of the means for the improvement of wheat aside from the mere introduction of valuable varieties. This is brought about by selection, and hybridization or 'breeding.' Examples of the latter are shown in a colored plate. The paper closes with a summary which contains many valuable practical suggestions.

CHARLES E. BESSEY.
THE UNIVERSITY OF NEBRASKA.

SCIENTIFIC NOTES AND NEWS.

THE officers of the International Association of Academies, which met last month at Paris, are as follows: *Honorary Presidents*, Dr. Mommsen, M. de Goeje, Sir Michael Foster, M. Berthelot, and M. Gaston Boissier; *Acting President*, M. Darboux; *Vice-President*, Dr. Diels; *Secretaries*, MM. Gomperz and Moissan. M. Darboux made an address of welcome, but otherwise the scientific work of the meeting has not been made public. We regret to learn that Professor G. L. Goodale, delegate from the National Academy of Sciences, was unable to

be present, having been detained at Geneva by illness.

MR. HERBERT SPENCER celebrated his eighty-first birthday on April 27th. Mr. Spencer lives quietly at Brighton. His health is fair, but he is not able to undertake much literary work.

THE Manchester Literary and Philosophical Society has awarded the Wilde gold medal to Dr. Metchnikoff, of the Pasteur Institute in Paris. The presentation was made at a meeting of the Society on April 22d, when Professor Metchnikoff delivered an address on the 'Bacterial Flora of the Intestine.'

THE King of Sweden has conferred on Professor J. H. Gore, of Columbian University, Knighthood of the Order of Wasa, in view of his services as a member of the Superior Jury and Committee of Five at the Paris Exposition.

PROFESSOR CHARLES HOWARD HINTON, of the University of Minnesota, has recently been appointed a computer at the U. S. Naval Observatory in Washington.

THE U. S. Department of Agriculture is about to establish an agricultural experiment station in Porto Rico, which will be under the direction of Mr. Frank D. Gardner, now of the Division of Soils.

DR. HARLOW BROOKS, instructor in the University and Bellevue Hospital Medical College, has been appointed pathologist to the New York Zoological Park.

THE corporation of Hull (Yorkshire, England) has recently taken over the Museum of the Literary and Philosophical Society in that town, and has appointed Mr. T. Sheppard as curator.

MR. O. P. AUSTIN, chief of the Bureau of Statistics of the Treasury Department, has gone abroad to study the statistical work of other nations.

DR. CORNELIA L. CLAPP, professor of zoology at Mt. Holyoke College, has been given a year's leave of absence which she will spend in study at Naples.

DR. B. T. GALLOWAY, director of the Bureau of Plant Industry, has been placed in charge of the seed distribution from the Department of Agriculture.

DR. TARLETON H. BEAN, who was superintendent of the New York Aquarium prior to April 1, 1898, was deprived of this position by the abolition of the office. A new position, entitled 'Superintendent of Small Parks,' was shortly afterwards created, and its incumbent was given charge of the Aquarium. Dr. Bean brought suit against the City for re-instatement, as he could not be legally discharged, and the office being abolished appeared to be a subterfuge. The Court has, however, now decided this suit in favor of the City authorities.

THE erection of a memorial to the late Right Hon. Professor T. H. Huxley in Ealing, near London, where he was born and received his early education, is contemplated. On the initiative of the Council of the Ealing Natural Science Society, a committee of those connected with the district who are interested in the project has been formed. The first meeting of this Committee was held on 29th of March last, when an executive committee was appointed (whose chairman is the Rev. Professor G. Henslow, Pres. Ealing Nat. Sci. Soc.). A bronze medallion portrait has been advocated for the central feature of the design, which may take the form of a simple mural tablet or of a more worthy monument as funds are obtainable, while should that support be forthcoming for which its projectors hope an annual grant or medal might also be founded. Subscription to the fund is not confined to the neighborhood or land of Huxley's birth, and those who may be desirous of assisting in the endeavor to keep green the memory of the great scientist in his natal town should communicate with the secretary to the fund, Mr. B. B. Woodward (120 The Grove, Ealing, London, W.).

PROFESSOR F. M. RAOULT, the eminent chemist, known for his important researches on the lowering of the freezing point and lowering the vapor tension of solvents by dissolved substances, has died at Grenoble at the age of seventy-one years.

DR. WILLIAM H. DRAPER, emeritus professor of clinical medicine in the College of Physicians and Surgeons, Columbia University, and one of the trustees of the University, died on April 26th, at the age of seventy years.

MR. E. S. NETTLETON, connected with the Department of Agriculture as an expert on irrigation, died at Denver on April 22d, at the age of sixty-nine years.

SHORTLY before the lamented death of Professor H. A. Rowland, his mechanician in the Physical Laboratory of the Johns Hopkins University, Mr. Theodore C. Schneider, died. He had been connected with the Laboratory ever since the founding of the University. Under Professor Rowland's personal supervision, he constructed the three machines used for ruling the spectrum gratings made at this laboratory and used in all parts of the world where exact measurements in spectroscopy are attempted; and for several years he has had exclusive charge of selecting and of adjusting the diamond points to the machine, and of ruling the gratings. The construction of these ruling machines involved the grinding of screws a foot or more in length, which should be as perfect as possible throughout their lengths. Mr. Schneider ground four of these screws which under the most severe tests to which they can be put have as yet shown no appreciable error. They are without doubt the most perfect screws in the world.

DR. GUILIO BIZZOZERO, professor of general pathology in the University of Turin, died on April 8th at the age of fifty-five years. He was the author of numerous important papers on changes in minute anatomy produced by disease and, more recently, on State medicine.

M. PAUL CHAIX, for many years professor of geography in the University of Geneva, has died at the advanced age of ninety-three years. He had traveled much and was the author of various works on geography.

WE also regret to announce the death of Dr. John Kloos, professor of geology and mineralogy in the Technical Institute at Braunschweig, at the age of fifty-eight years; and of Dr. Daniel Wierzbicki, astronomer in the observatory at Cracow, at the age of sixty-eight years.

THE first *conversazione* of the Royal Society will take place on Wednesday, May 8th.

THE Government of Norway and Sweden has called a conference of representatives of countries interested in marine exploration to meet in Christiania in May. Germany, Great Britain' Denmark, Holland and Russia, besides Norway and Sweden, have indicated their intention to send delegates, and it is expected that other countries will be represented.

A TELEGRAM was received at the Harvard College Observatory, on April 26th, from Professor Kreutz, at Kiel Observatory, stating that a very bright comet, discovered by Halle at Queenstown, April 23d, was observed at Capetown by Gill, April 24d.712, Greenwich mean time in R. A. 1h. 30m. 4s. and Dec. $+ 3°$ $27'$. The comet was observed by Professor E. B. Frost at the Yerkes Observatory on the 27th, just before sunrise and close to the sun.

GOVERNOR ODELL has signed the bill which permits New York City to accept the $5,200,000 gift of Mr. Andrew Carnegie for a free library system. The bill was drawn by Corporation Counsel Whalen and authorizes the city to purchase, erect and maintain libraries, and to enter into a contract with Mr. Carnegie to accept his gift under the conditions named by him.

THE workshop for the grinding of lenses and construction of telescopes, established by Mr. Alvan Clark, which was purchased from the heirs by one of his daughters, Mrs. William H. Grogan, Jr., and conducted by Mr. Grogan until his death last July, has been sold to the Alvan Clark and Company corporation.

BEGINNING on about the fifteenth of May, 1901, the Biological Department of the University of California will commence a systematic biological survey of the coast of that State. Temporary headquarters are established at San Pedro, and the work for the first summer will be carried south from Pt. Conception toward San Diego. A gasoline launch, which has been obtained for the season, will be fitted out with apparatus for dredging, sounding and making observations on temperature, salinity, specific gravity, etc. The work will be carried on by the members of the Department and graduate students, together with a number of investigators who have already interested themselves especially in west coast faunas. The funds to be used in the work were raised by Mr. W. H. O'Melveny, a graduate of the University, among the citizens of Los Angeles.

THE Mining School of McGill University will this year carry on its summer work in British Columbia. The class expected to leave Montreal by special car on the Canadian Pacific Railway on May 1st, and to go out to the Pacific coast, visiting the various collieries along the line of the railway and on Vancouver Island. The party will then go into southern British Columbia for the purpose of studying the mineral deposits of the Slocan, Trail Creek and Boundary Districts, and, returning by the Crows' Nest Pass route, will visit the coal mines at Fernie Hethbridge, reaching Montreal again about the middle of June.

THE daily papers state that a party of students from Harvard University will undertake, this summer, an expedition to Venezuela for botanical and zoological research. They are to leave New York on the steamer *Caracas*, on June 15th, and will proceed to La Guayra and Margarita Island.

THE assignment of field parties by the U. S. Geological Survey for the present season are as follows: Arizona: T. A. Jaggar, Waldemar Lindgren, J. M. Boutwell, F. L. Ransome, John D. Irving and R. T. Hill; Arkansas: George I. Adams; California: George F. Becker, W. Lindgren, J. C. Branner, J. S. Diller, Geo. H. Eldridge and H. W. Turner; Colorado: C. W. Cross, Ernest Howe, J. Morgan Clements, S. F. Emmons, John D. Irving and George I. Adams; Connecticut: William H. Hobbs and H. E. Gregory; Delaware: R. D. Salisbury and George B. Shattuck; Georgia: Arthur Keith; Idaho: Bailey Willis; Indiana: George H. Ashley; Indian Territory: J. A. Taff and George I. Adams; Kansas: W. S. Tangier-Smith; Kentucky: M. R. Campbell and George H. Ashley; Louisiana: George I. Adams; Maryland: Continuation of cooperative work as in previous years, William B. Clark, E. B. Matthews and George B. Shattuck, study of ancient crystalline rocks, paleozoic stratigraphy and coastal plain deposits; Massachusetts: B. K. Emerson; Michigan: Frank Leverett, F. B. Taylor, C. R. Van Hise, C. K. Leith and W. S. Bayley; Minnesota: C. R. Van Hise and J. Morgan Clements; Missouri: W. S. Tangier-Smith; Montana: Continuation of special studies in the Rocky Mountains, Charles D. Walcott, director; W. E. Weed and Bailey Willis; Nevada: G. K. Gilbert; New Jersey: R. D. Salisbury and George B. Shattuck; New Mexico: George H. Girty, R. T. Hill and C. W. Cross; New York: L. C. Glenn, T. N. Dale and J. F. Kemp; North Carolina: Arthur Keith; North Dakota: N. H. Darton and C. M. Hall; Ohio: Charles S. Prosser; Oklahoma: J. A. Taff; Oregon: J. S. Diller; Pennsylvania: Parts of Butler, Armstrong, Indiana, Washington, Westmoreland, Fayette and Tioga counties, M. R. Campbell, A. C. Spencer, George B. Richardson and L. Fuller; northern Pennsylvania: George H. Girty; Philadelphia and vicinity, Professor Florence Bascom and C. R. Van Hise; refractory clays of Pennsylvania, C. W. Hayes; Fulton and Franklin counties, George W. Stone; coal measures, C. D. White; South Carolina: Arthur Keith; South Dakota: N. H. Darton and J. E. Todd; Tennessee: Arthur Keith; Texas, R. T. Hill and George I. Adams; Utah: C. K. Gilbert; Vermont: T. N. Dale and J. E. Wolff; Washington: F. L. Ransome and Geo. Otis Smith; West Virginia: Cooperation with State survey under Professor I. C. White; Wayne county: M. R. Campbell, survey of Ceredo quadrangle; Wisconsin: C. R. Van Hise and W. C. Alden; Wyoming: W. C. Knight, N. H. Darton, George I. Adams and Arnold Hague.

THE correspondent from India of the London *Lancet*, writes under date of March 28th: "Plague has caused 11,560 deaths throughout India during the past week. The mortality is increasing with alarming rapidity in the Lower Provinces. Of the above total, no fewer than 7,315 deaths occurred in the Bengal districts. In Calcutta there were 1,040 deaths. The plague cases reported in this city were 1,199 against 993 during the previous week and the number of fresh living cases seen was 345. Disinfection continues to be extensively practiced, not only in respect of the rooms and houses where the cases occur, but in many of the adjoining houses. The process adopted consists in flushing the floors and spraying the walls with the standard solution of perchloride of mercury. Cases continue to occur in

the disinfected quarters, and it is impossible to show that the measure possesses much value. The outbreak in Calcutta now is more severe than that of last year, notwithstanding the repeated disinfections which have been practiced. As I have before remarked, however, the authorities are apparently able to account for nearly all the plague deaths and the investigations made after death indicate the exact location of the cases. The reported plague deaths in Calcutta nearly account for the excess mortality, and that is more than can be said for any other city. The disease is spreading in Benares and has reached to the cantonment. It continues to progress from village to village in the Gardaspur and Sialkot districts of the Punjab. In Bombay city plague has caused over 1,000 deaths during the past week. An examination of the total deaths in this city since the plague appeared in 1896, shows an excess mortality over the average of 120,000. The official reports only give 60,000 deaths from plague since its commencement in September, 1896, so that there is a very large balance to be accounted for. If the system adopted in Calcutta had been applied to Bombay, it is most probable that the greater part of this excess would have been found to be due to plague, and it is almost safe to say that Bombay city has lost 100,000 of its inhabitants from plague."

Nature learns from the *Victorian Naturalist* that Professor Spencer, F.R.S., of the Melbourne University, and Mr. F. J. Gillen, of South Australia, were expected to start from Oodnadatta, the present terminus of the transcontinental railway, nearly 700 miles north of Adelaide, on their expedition for the purpose of studying the habits and customs of the aboriginals of the northern portion of Central Australia, about the middle of April. The start has been somewhat delayed owing to the drought which has existed for some time in the portion of the continent to be visited. It is also proposed to cross into Queensland and continue Dr. Roth's ethnological work, and afterwards to traverse some of the larger rivers of the Northern Territory, and, if time permit, to visit the Wyndham district on Cambridge Gulf in Northwest Australia.

AN Institute for Tropical Hygiene was opened in Hamburg at the beginning of March. According to the *British Medical Journal*, it is a combination of laboratory and hospital, and the scientific workers in the first department will be able to find their material 'on the premises,' so to speak. The building has been erected close by the harbor; one wing contains 50 beds for tropical cases, such as malaria, beri-beri, etc. (not for infectious diseases); the second wing is taken up by the laboratories, lecture halls, etc. Here courses of lectures, combined with practical work, are to be held for the benefit of ship surgeons, navy surgeons, doctors about to settle in the colonies, and colonial medical officers of the State. The Institute has been erected by and belongs to the Free State of Hamburg, but the German Empire contributes a share of the working expenses, and the disposal of a certain number of laboratory places.

AT the last monthly general meeting of the Zoological Society of London, it was stated that there had been 106 additions to the Society's menagerie during the month of March, amongst which special attention was directed to the male Tasmanian wolf (*Thylacinus cynocephalus*), seldom seen in captivity, and also to the Indian birds presented by Mr. E. W. Harper, of Calcutta, new to the Society's series. It was also stated that on Easter Monday the admissions to the Society's gardens were 46,599, being a larger number than had ever passed the gates in one day since the opening of the gardens to the public in 1828. At the close of the general meeting the first of the annual series of lectures was delivered by Professor Charles Stewart, entitled 'On the Protection and Nourishment of Young Fishes.'

UNIVERSITY AND EDUCATIONAL NEWS.

AT a recent meeting of the regents of the University of Kansas, arrangements were made for the expenditure of the $10,000 appropriated by the Legislature, for improvements in the new chemistry building, and it was also decided to purchase a liquid-air plant. $7,000 will be

expended for additions to the library, including binding. Competitive plans for the natural history museum building, for which $75,000 has been appropriated, and the plans of Messrs. Root and Siemans of Kansas City were accepted. This building, which is to be constructed of native stone, will be of the Romanesque style of Southern France, and adapted especially for the display of the North American mammals and other extensive collections owned by the University. It will be practically fireproof in construction and will be three stories in height. The regents will also provide for assistants in the departments of mathematics, English and history, and the men have been practically selected for these positions.

Owing to the increased appropriation made by the Legislature, the University of California has been enabled to enlarge a number of departments. The chair of mechanical engineering is to be divided, the present occupant of that chair, Professor Hesse, becoming professor of hydraulics, while the former associate, Professor Cory, returns to the department (after a year's absence in industrial work) as professor of electrical engineering. The following new instructors were also authorized by the regents at their meeting on May 19th. Two instructors in chemistry, an instructor in civil engineering, an instructor in steam engineering, an instructor in philosophy, an assistant in mechanics and two assistants in physics. The estimates for next year amount to about $550,000, of which $344,000 are for salaries and $60,000 are for permanent improvements.

The arrangements for the celebration of the bi-centennial of the Yale University in October next have now been made public. The addresses include one by President Gilman, of the Johns Hopkins University, on 'Yale in its Relation to Science and Letters' and one by Professor W. H. Welch, of the same University, on 'Yale in its Relation to Medicine.'

The freshman and sophomore classes of Rush Medical College will be transferred to the buildings in Hull court at the University of Chicago, and after July 1st the work of the two upper years only will be done in the Rush buildings on West Harrison and Wood streets. More than $50,000 has been recently given to the University of Chicago for the additional equipment required. The new arrangement means that 300 medical students will be at work in the University of Chicago proper by next fall. The work of the two upper classes is clinical and must be done near the hospitals. They will have all the facilities of the old building and of a new $110,000 building on which work has already been commenced.

At a special meeting of the council of University College, Liverpool, on April 16th, the following resolutions were adopted:

1. That, while gratefully acknowledging the advantages which have accrued to University College, Liverpool, by its association with Victoria University, this council is of opinion that a university should be established in the city of Liverpool; that this council will welcome a scheme with this object upon an adequate basis; and that a committee be appointed to consider and report upon the whole question, with power to make inquiries and to communicate with other bodies.

2. That the committee consist of all the members of council, with power to associate with them any other persons whom they may think fit.

Dr. Aristides Agramonte, formerly chief of the bacteriological laboratory, has been appointed to the chair of bacteriology and experimental pathology in the medical faculty of the University of Havana, Cuba.

Dr. H. S. Jennings has been promoted at the University of Michigan from an instructorship in zoology to an assistant professorship.

Mr. H. W. Kuhn, who is to receive his doctorate from Cornell University in June, having been a scholar, fellow and assistant there during the last three years, respectively, has been appointed an assistant professor in mathematics in the Ohio State University, from which institution he was graduated in 1897. After graduation, Mr. Kuhn was a fellow and assistant in his alma mater for one year. His investigations thus far have been chiefly in a theory of substitution groups—several papers by him in this line have been read before the American Mathematical Society.

At Bryn Mawr College, Miss Harriet Brooks, A.B. (McGill University), has been awarded a fellowship in physics.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, MAY 10, 1901.

CONTENTS:

The Dignity of Chemistry: DR. H. W. WILEY... 721

Diamond-Glass Fluorescence: DR. ARTHUR L. FOLEY ... 732

How Botany is Studied and Taught in Japan: KRICHI MIYAKÉ ... 734

Scientific Books:—
Schuyler on Reservoirs for Irrigation, Water Power and Domestic Water Supply: PROFESSOR I. P. CHURCH. *Annual Report of the War Department:* PROFESSOR R. H. THURSTON. *Titchener's Experimental Psychology:* PROFESSOR JOSEPH JASTROW. *Pierce on Peach Leaf Curl. Books Received* ... 738

Societies and Academies:—
American Mathematical Society: DR. EDWARD KASNER. *Zoological Journal Club of the University of Michigan:* PROFESSOR H. S. JENNINGS ... 744

Discussion and Correspondence:—
Correction to André's Astronomie stellaire: PROFESSOR GEORGE C. COMSTOCK. *An Appeal for Cooperation in Magnetic and Allied Observations during the Total Solar Eclipse of May 17–18, 1901:* DR. L. A. BAUER. *Clayton's Eclipse Cyclone and the Diurnal Cyclones:* H. HELM CLAYTON. *Leland Stanford Junior University:* PROFESSOR J. C. BRANNER and others ... 746

Current Notes on Physiography:—
Topographic Atlas of the United States; Terraces fronting the Rocky Mountains; The Formation of Deserts: PROFESSOR W. M. DAVIS ... 751

The American Geographical Society ... 753

Resolution of the Committee of Central Naturalists ... 753

Scientific Positions under the Government ... 754

Scientific Notes and News ... 755

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

*THE DIGNITY OF CHEMISTRY.**

CHEMISTRY as a profession may be said to have completed its hundredth year, and we have met to-night to celebrate the quarto-centennial of chemical organization in America.

In our democratic country, all attempts to create a class or caste should be discouraged, especially if the attempt be made to endow the class with unusual or special privileges. We have no place for an hereditary or purchasable aristocracy, but in the function of the civic body there must be specialization, and those individuals who by choice or fortuitous incident devote themselves to special duties are brought together by occupation, by congeniality and by desire for mutual helpfulness and improvement. In this mutual attraction we find the genesis of all trade and professional organization. The aggregate is always stronger than the segregate. This unity of purpose and this conformity of effort become reprehensible only when autocratic, imperative and insolent. The assumption of superior virtues, the assertion of peculiar privileges and the interference with the rights of others are never to be advocated nor condoned.

* An address delivered before the American Chemical Society, April 12, 1901, on the occasion of the celebration of the 25th anniversary of the founding of the Society.

Every honest effort to earn a living and a competency is worthy of equal praise, and therefore in dignity of effort there is no rank. The workman in the woods, the farmer in the fields, the artisan in the atelier and the mechanic in the mill have an equal claim to the dignity of labor with the preacher, the lawyer and the professor. There is no form of labor which is beneath the dignity of any man. Instead of being a curse, labor is the greatest blessing which Providence, fate or evolution has conferred on humanity. Tolstoy, one of the greatest of living novelists, earns his living from the soil. Peter the Great was a carpenter and is said to have done much of the work in building the old palace at Peterhof. Louis XVI. was a locksmith. Washington was a farmer, Lincoln a railsplitter, Grant a tanner, Garfield a canal boy. The natural and normal desire of men who have achieved greatness is for a piece of land where they can be in touch with the great mother of us all, the soil. To him who appreciates the true dignity of labor, no task is menial. The hands are made for toil as much as for fighting, and sweat is the most efficacious of all detergents. In derision on one occasion the Romans made Cato commissioner of sewers, but he discharged the duties of his menial office with such industry and benefit to the city that thereafter to be made commissioner of sewers was considered to be a distinguished honor.

So the true philosophy should teach us that our calling in life is a *cloacum magnum* which we are to administer, not with closed nostrils, but with open eyes and hands that do not recoil before thickened cuticle and stains.

He who is not proud of his profession is not worthy of it. This does not mean that his profession is any better than another, but when the heart is not in the work the head is sluggish and the hands are slow. Nor do I mean that a profession should not be regarded as a means of making a living. On the contrary, that is the first and chief end of any occupation. The number of persons who work alone for the love of it is exceedingly small. Perhaps there is only one profession where it is better that a man be rich, and that is the profession of politics. Making a living out of a public position is the most precarious of all professions, and there is no collection of dependent fossils which appeals so pathetically to general commiseration as that vast aggregation of exes which lingers near the cupola of the Capitol. The *functus officio* faster has fed so long at the public crib that he knows not the taste of other food nor the means of getting it. The last of his life is an eternal Lent on which no Easter morn of soothing satiety will ever rise.

In one short walk a few days ago, I met one ex-senator and two ex-representatives, who a few years ago were farming patronage and feasting on lobster Newburgh at Chamberlins, who are now seeking to be attorneys for the holders of claims that live only in the hope that a far-off indulgent future will no longer know their worthlessness. Hungry are the looks of these men, with jaws cavernous as those of Cassius, and sad warnings of the fate of a statesman out of a job. A profession, therefore, should offer some guaranty of a livelihood dependent on merit and industry, and not upon the whim of a capricious public.

It is not my purpose to-night to discuss chemistry as a living-provider. Often young men come to me and ask my advice in regard to choosing a profession. They come often with a strong inclination to chemistry and want to know what I think of the prospects for success. If they have already studied chemistry, I invariably ask: Have you a taste for chemistry? Do you love chemical studies? If they do not know, or if the answers are indefinite or

evasive, my advice is always, "Stay out." But especially is this so if they propose to study chemistry as a profession because it is an easy road to wealth. Alas! the paths of chemistry seldom lead to 'easy street.' True it is, you rarely see the chemist begging bread. Perhaps he knows too well of what it is composed. The chemist tramp too, is a kind of a *rara avis in terris cygno simillima nigra*. The chemist may be able to change phosphorus into arsenic by oxidizing it in presence of ammonia, but even so distinguished a man as Carey Lea could only make silver yellow, and further than this scientific transmutations have not extended. Fortunes have been made by a few. A happy discovery in metallurgy or in manufacturing processes has often brought a modest fortune to the inventor, but most of the roads leading from the Patent Office end in the cemetery of hopes at first vigorous from the pliant pabulum labeled 'Having now described my invention what I claim is,' etc., 'substantially as set forth.' The parchments with the flaming seals that protect you in the sole usufruct of your genius for a period of 17 years serve most frequently as fitting cerements for the deceased. If the chemist be a teacher or employed at a salary the prospect for a competence is not much better. At best these stipends are not very large. In a manufacturing enterprise, the chemist often becomes the manager, and in this case he can put by something for 'a rainy day.' If a professor, he sometimes gets to be the president of the college, provided his theology is untainted. But Universities of Chicago are not found in every academic grove. Most of our institutes of higher learning are chronically impecunious, and even the professional chair is not upholstered with a cushion which would tempt the expectant Croesus.

In general, then, it must be admitted that whatever of dignity is due the profession of chemistry is not attributable to its tendency to wealth.

I am not of that school which despises wealth, nor yet of the cult that loves it. Poverty, doubtless, has its uses in evolution and molding of character. Wealth often corrupts youth and makes of manhood but a purveyor of vice. But poverty also invites crime, and is not the most efficient preservative of virtue. A modest competence, possibly, is the ideal state, best suited to highest development and greatest usefulness. It is not always dignified to be in debt. For this reason, I should like to see the influence of this great organization whose foundation we celebrate to-night, exerted to secure better pay and more permanent employment for its members. I know this seems sordid and mercenary, but we must not always live in the clouds. The cerulean atmosphere will be more gratefully stimulating and its views be more thoroughly appreciated if we manage somehow to keep our feet well braced on terra firma. To him who cannot swim, things begin to feel a little queer when the advancing tide leaves him touching only a little flowing sand with the tips of his toes. Good and steady pay, therefore, to its devotees is no small contribution to the dignity of chemistry.

The pursuit of science is nothing else than an effort to know something of the constitution of the natural world. That knowledge is not derived from an ingenious system of vain imaginings, but is secured by a study of nature herself.

"To him who in the love of nature holds communion with her visible forms she speaks a various language," sang one of our great poets at the age of 17. Had he lived until he was 100 and grown in wisdom every year he could not have touched a truer note. The language which nature speaks to the chemist is a description of the ultimate nature of things. It is to the

chemist that nature teaches the alphabet of human knowledge. In this sense the chemist comes nearer than any other to first principles. As we grow in knowledge, we sometimes forget our small beginnings. And so it sometimes seems to me that our professional brethren of other schools are prone to despise the day of little things. Atoms and molecules are too small to cut much of a figure in the economy of nature, think some. But it is no true mark of greatness for the macrocosm to forget the microcosm. A megatherium is not the 'whole show.' It is true that in some respects chemical achievements appeal least of all scientific accomplishments to the popular attention. The isolation of krypton does not have half the interest for the public that attaches to the discovery of a new bug, especially if it have domestic tastes. In fact all the biological sciences, with the possible exception of physics, find a readier and more appreciative public than those which deal with things lifeless and for the most part incomprehensible to the layman. This truth is uttered in no complaining mood, but only to explain why Davy is not as well known as Darwin, nor Hoffmann as Haeckel. It is when chemical studies and discoveries come directly into contact with life that they lead to recognition, as in the case of Pasteur, whose great genius is recognized the world over, perhaps more generally than that of any other scientific man has ever been. But it is not alone for public applause that life is worth living, and the dignity of our science suffers no depreciation because of its apparent remoteness from human interest. I say apparent, because I do not believe that any other science has in reality any nearer bearing on human welfare than chemistry. Think for a moment how many of our industries that lie at the foundation of wealth and progress are based directly on chemistry. Think of the many others that are intimately related to it indirectly. If the clock of political progress and liberty were turned back 50 years by the battle of Waterloo, think of the loss to humanity should such a disaster befall the hosts of chemistry. Bourbonism is the natural foe of human progress, and unhappily the world is still full of anti-scientific Bourbons.

Whatever may be the branch of the profession which the chemist may pursue, he should not be indifferent to feelings of justifiable pride which come to him when he realizes all that our science has done for humanity. The disciples of evolution may have attached some opprobrium to the epithet, but the chemist is the 'connecting link' between the world of matter and mankind. We stand the nearest of all our brethren to the ultimate constitution of things, so near, in fact, that we almost tremble at the thought that by some subtile synthesis we may yet strike the spark of organic life. Of one thing at least we may feel sure. We know best of all our brethren the environment of development and growth. We may never create an environment which will make autogenesis possible, but we surely can soften some of the harder conditions of existence. To be so near the first forms of life, to be so nearly in touch with the ultimate secrets of nature, are facts which show some of the principal elements of the dignity of chemistry.

No man can lay claim to the term scientific who does not reverence the truth. That is the first element of a scientific mind. The truest proof of a reverence for the truth is a willingness to be convinced. In the times of Cromwell, the truth was supposed to be simply the dogmas of the creed, which led Hudibras to say :

> "Convince a man against his will,
> He'll hold the same opinion still,
> And prove his doctrine orthodox
> By apostolic blows and knocks."

The most difficult mental attitude, which the scientific man has to contend with in his struggle for the truth, is bias. We inherit, in a measure, certain notions of things and of life. This natural inheritance is strengthened by the earlier teachings of childhood, so when we reach the age of maturity we have formed certain opinions, we are endowed with certain habits of thought which tend to dominate our mental attitude. Happily, most of these habits and most of these inheritances are sound, but now and then we find one which is clearly opposed to the conditions of existence as science reveals them. How difficult in this case to let go the old notion; how hard to bring one's self into an attitude to receive the truth! Perhaps it is only a species of conservatism which leads man to hold on to that which he has, and in this sense a certain difficulty of conviction is a guaranty of stability of thought and of social, economic and political conditions. In other words, we should heed the warning in the Bible and not be swayed by every 'wind of doctrine.' The tendency to too eagerly accept is more reprehensible than tardiness of belief. We have all seen wave after wave of illogical belief sweep over the country, and no difference how absurd a theory may be or how impossible a course of action which is marked out, it finds plenty of adherents. This instability tends to render all the conditions of natural growth and development precarious. The scientific man must be on his guard against being buncoed by any plausible or specious doctrine, as well as to keep his mind open for the acceptance of the truth. Here is where judgment comes into play, and not only should the scientific mind be open to conviction, but it should also be controlled by a sober and discreet judgment which can discriminate between the true and the false in evidence. But when soberly considered, certain facts are brought home with an overwhelming evidence of truthfulness, the results of this evidence should be accepted, no matter how contrary they may be to our preconceived notions. Perhaps the greatest offense in this direction which the scientific man commits is a distortion of evidence to suit the case. By a slight inclination this way or that from the true point of direction an observed fact may be made to support this or that theory or condition. I am far from belittling the value of theory. When formed on substantial evidence and with a becoming ingenuity it is a valuable aid in the discovery of further truth, but a theory should never be a fetich to be reverenced and worshipped with the blind devotion of the religious devotee. There is nothing sacred about the theory. It is only a valuable tool to be cast aside when a better or more effective one is at hand. The dignity of our profession, therefore, has been strengthened and increased by the habit of the chemical mind of accepting the dicta which experimental evidence has provided. Detracting somewhat, however, from this dignity has been the fact that certain contentions have arisen in our profession over the interpretation of ascertained phenomena. Chemists may agree upon the character of certain phenomena which are presented, but construe them differently, and often with acrimony. A scientific discussion should be conducted with all the dignity of a scientific dissertation, and the honest differences between chemists should never be allowed to degenerate into personalities or innuendo. There is no excuse whatever for speaking slightingly of the honesty or ability of a brother chemist who may happen to differ from you in his opinion of phenomena. Envy, backbiting, slander and scandal have no place in the chemical profession. I believe every one will admit that there has been less of it in the profession of chemistry than in almost any other. We know to what extent the per-

sonal quarrels among many scientific men have been carried in this country, and we are glad to say that there is no instance in which these quarrels between chemists have come into our organization to influence our action and mold our policies or to cause the growth of faction and the promotion of feuds.

There is enough for every one to do in this country without wasting his energies with envy of the accomplishment of others. About the most unprofitable occupation into which a man can fall is to complain of a lack of appreciation. It is doubtless true that in many cases the worthy man is cheated of his dues and the unworthy receives a reward out of all proportion to his services. These are accidents, which are due to the imperfection of human nature, and not to any peculiarity of scientific pursuits. There should be room for the philosophy of life in chemical science as in every other. The sensible way is to accept what happens, and not to degenerate into a kicker or the carrier of a club. The chips which are found on the shoulders of our associates are usually magnifications of the motes in our own eyes, and not due to the deposition of any really ligneous material upon the clavicle of our supposed enemy. We have plenty to do in this world without going about knocking off hypothetical chips. I have the profoundest sympathy for the man with a just grievance, and I know how many have them, but there is no greater nuisance than this same man with this same just grievance. The man who shuts his mouth, compresses his lips and bears the pain and humiliation without a sign is the one who wins our admiration in the end and often turns disaster into good.

With a proper appreciation of the dignity of our profession, we will therefore do our work as well as we can and be glad of the greater success of our professional brethren, and not find in it a cause of sorrow and dejection. Every man who succeeds in chemistry does a work to elevate our profession and to help us all, and therefore, even from a selfish motive, we should be glad of his achievements. I realize how hard it is to see others preferred when we feel convinced that we should have had it, and yet I must be allowed to praise the courage of the man who with a smile on his face and a true feeling of well-wishing in his heart can congratulate the more successful man not with hypocritical words, but with a real sentiment of satisfaction.

There is one special way in which I think our great organization can do much to elevate the dignity of chemical science. I have spoken of the fact that chemistry does not appeal directly to the public imagination, and for this reason many of our best people do not have a true appreciation of the value of chemical services. An honorable and praiseworthy part of our profession is the rendering of professional services of a chemico-technical nature to the great industries of the world. Too often the promoters of these industries, the men with the money, the men on the boards of directors, and the stockholders, do not appreciate the real value of the services they ask for. A great corporation is perfectly willing to pay a great lawyer $10,000, $15,000 or even $50,000 for professional services, whereas if a chemical expert should ask $1,000, it would produce a kind of corporative hysteria or nervous prostration, while, in point of fact, the technical services demanded would probably be of far greater financial utility than the legal services so much more liberally paid for.

There has been a tendency among some of our profession to foster this spirit of contempt for the value of chemical services of a professional nature, not intentionally, I am glad to say, but because of a feeling, which I can hardly describe, that it is not

dignified for a chemist to sell his services for money. The falseness of this position, it seems to me, has been fully set forth in the earlier part of this address, and I believe that every right-minded person will admit that it is not derogatory to dignity to receive pay. Otherwise, I should think that we should cast dignity to the winds and look out for the 'main chance.' In my opinion, it is just as honorable and worthy to give professional advice to a great industry as it is to discover an unknown element. In our society we should have far more *esprit de corps*, more regard for the rights and privileges of each other, and a better understanding of the ethics of our profession. It is true that we now act upon the principle that it is dishonorable to take an investigation out of the hands of a brother who has once commenced it, without his permission, or in any way to trespass upon the fields which he has preempted. In like manner we have learned that it is dishonorable to underbid a professional brother in offering our professional services. It seems to me that the Society can do a great good towards promoting the dignity of our profession in this way by establishing not a hard and fast schedule of prices for professional services, but by bringing closer together our members who give these services so they may have a better understanding of the rights and privileges of each other. Other professions do this, especially the medical, and great benefit would be derived from a better understanding in regard to these matters.

Especially is this true from the effect it would have upon the public at large who, seeing a profession stand together and in a dignified manner demand what is right and just, would better appreciate the value of the services which they often hope to get for the very smallest possible consideration.

Perhaps the bitterest criticism to which the chemist has been subjected has grown out of his services as expert before the courts. Here we often have the spectacle of two men, under oath, one in affirmation, one in negation. It is only natural that the expert should favor his client, but that favor should never go so far as to impugn the truth. When there is room for disagreement, I can see no impropriety in the chemist supporting with all his ability the side that employs him. He is not hired to discuss the whole problem in all its aspects, but to develop those points which make for the benefit of his employer. We cast no reflection on the honesty of the lawyer who defends, nor should we on the rectitude of the witness who testifies. But no worthy chemist will deliberately undertake to support a falsehood. Whatever of viciousness may attach to expert evidence is the fault of the system rather than of the witness. We all admit that it would be far better for the court to employ the expert, and not the plaintiff or defendant. But until that change has been made, the chemist is undoubtedly right in making out the best case possible for his client, provided he distorts no facts.

How far he can go with patent medicines, nostrums and secret preparations is another story. The dignity of our profession forbids any taint of humbug or quackery. This field, therefore, seems to be absolutely closed for professional purposes.

I would not have our Society become a trades union, and especially would I be sorry to see it exercise the tyranny which such unions often manifest, but I would like to see a better understanding established in matters of this kind, both for the sake of our members and for the benefit of the public at large.

The dignity of the profession of chemistry is illustrated in a striking way by the active participation which it exercises in many of the greater walks of life. I have not time

here to go into statistics and show the relative number of chemists employed in the industries as compared with members of other scientific professions. We will admit without such an array of figures that there is no other scientific profession, with the possible exception of physics, which begins to be so numerously represented in the great industries as the science of chemistry, and even in the case of physics, aside from the electrical industries and those of a purely engineering character, the physicists engaged in the active industries are not numerous.

When it comes to mining engineering, we find that the engineer himself must be a chemist in order to be fully able to discharge the duties of his profession. In so far as statistics are concerned, I will content myself with a few citations showing the preponderance of chemical employees in the great scientific agricultural industries of our country.

In a study of the impress which chemical research has made upon agriculture, there has been no factor during the past twenty years which can compare with the work of the agricultural experiment stations of the United States. Richly endowed as they are by the General Government, they have had every opportunity to secure the best results for practical agriculture.

In this work chemical science has played a very important part in the furthering of agricultural prosperity. Of the forty-nine directors of the stations at the present time twenty were professional chemists at the time of their appointment. The selection of so many professional chemists was no mere chance, but evidently had some relation to the dominant position which the science of chemistry holds to the promotion of agricultural chemical research. The list of directors of the agricultural experiment stations of Germany shows the same condition of affairs.

The great influence of chemistry on the agricultural experiment stations of this country is not measured alone by the number of professional chemists which is found in the directorates, but also by a comparison of this number with that of other scientific men holding similar positions. Very few of the other sciences are represented among the directors of stations, and no one of them can compare in its number of representatives to the science of chemistry. Among the working forces of the stations chemists also predominate. There are twice as many chemists employed in the stations as there are men engaged in any other professional scientific work. Statistics show that the number of chemists employed in the agricultural experiment stations of the United States is one hundred and fifty-seven, while the number of botanists is fifty and the number of entomologists forty-two. The number of employees belonging to other branches of science is very much less than that of the botanists and entomologists, and the total number of scientific men employed in all other branches of scientific work in the station does not greatly exceed, even if it be equal to, the number of those employed in chemical research alone.

While dwelling upon the predominance of professional chemists in the directorates and upon the staffs of the experiment stations, it seems eminently proper to mention here in a special manner some of the earlier eminent chemists who have contributed so much to the value of chemical research in our agricultural colleges and experiment stations. Among these must be mentioned Professor F. H. Storer, of the Bussey Institute (Massachusetts), who first began the regular publication of a bulletin recording the work of the school and station, which has 'set the step to which the bulletins from many other stations are still marching.' The bulletins of the Bussey Institute describing original research work on agricul-

tural subjects have proved of the highest benefit to agriculture. Professor Storer's work, entitled 'Chemistry in some of its Relations to Agriculture,' the first edition of which was published in 1887, has had a marked effect upon agriculture in this country.

As early as 1846 Yale University, then called Yale College, appointed a professor of agricultural chemistry. This was John Pitkin Norton, who had devoted himself to the study of scientific agriculture both in this country and in Europe, especially with the celebrated Liebig. He brought to his position a ripe knowledge and wisely directed enthusiasm for agriculture, which he used with the greatest profit in its service. In 1855 Samuel William Johnson was appointed instructor in agricultural and analytical chemistry, and soon after full professor. Perhaps no one ever succeeded more fully in popularizing scientific agriculture than Professor Johnson. His two books, 'How Plants Feed' and 'How Plants Grow,' the first editions of which were published in 1868 and 1870, respectively, have been kept abreast of modern progress in successive editions, and are still used as standard text-books and as authorities on the practical relation of chemistry to agriculture.

In the University of California, the work of Professor E. W. Hilgard must be mentioned as being of fundamental importance in the development of the relation of chemistry to agriculture in this country. Professor Hilgard, in his classical work on soils, has placed himself in the front rank of investigators on this subject, not only in this country, but in the world, and his achievements have been recognized both by his countrymen and by the most celebrated societies of Europe. A knowledge of the soil and its relation to plant growth constitutes one of the fundamental principles of agriculture chemistry, and the researches of Professor Hilgard in this line have done much to place agriculture in the United States on a strictly scientific basis.

At Cornell, even before her doors were open to students, a professorship in agricultural chemistry was established. Professor G. C. Caldwell was appointed to fill this position, and he has done so with distinction to himself and to the University and with the greatest benefit to agriculture. One of the most important services in connection with Professor Caldwell's labors at Cornell was the publication of his work on agricultural chemical analysis in 1869. At that time no work of a similar nature existed in the English language, and Professor Caldwell's book was a veritable boon to students in agricultural science.

This brief reference to the contributions of some of the earlier workers in agricultural chemical science in this country would not be complete without mention of the labors of Professor C. A. Goessmann, of the Massachusetts Agricultural College.

It is not possible in the space assigned to this address to even name the more prominent later workers.

A national epoch in agricultural education in this country began with the passage of the Morrill Act, in 1862, establishing and endowing colleges where agriculture should be one of the principal branches in which instruction is given. An additional impetus was given to this great work in 1887 by the passage of the Hatch Act, establishing agricultural experiment stations in the several States. The organization list of the agricultural colleges of the United States now shows the great number of men working in lines of agricultural chemistry. This most remarkable evolution of agricultural education has taken place practically within the last thirty years, and there is no country which can now be compared with the United States in the munificence of the endowment for agri-

cultural chemical research or in the vast amount of research and experimental work conducted in these lines.

Another way in which our profession has influenced higher education in this country is found in the large number of chemists who have been called to preside over our higher institutions of learning. Of the leading institutions in this country, Harvard University, Lehigh University, the University of North Carolina, the University of Tennessee and Purdue University are presided over by professional chemists, or rather, I should say, by those who before elevation to the presidential rank were professional chemists. I doubt if any other branch of science can show so many college and university presidents as our own. It is certainly not a mere accident that in the breaking away from the old scholastic habit of placing ministers of the gospel over institutions of learning, chemistry has received so marked a favor. In fact, the pursuits of chemical science, it seems to me, tend more than other scientific occupations to broaden the mind and to bring it in contact with all the varied industries and forces of active life. It is true that other branches of science have their economic aspects, and we do not by any means desire to minimize that important relation, but they do not come so generally into contact with human affairs. While they appeal in the nature of their services more to the public imagination, when it comes to real practice they do not have that influence which our own science possesses.

I am far from saying that the pursuit of chemical studies tends, in any peculiar way, to develop administrative ability, and hence it cannot be in this collateral way that so many of our brethren have reached these higher places of administrative effort.

While we do not claim that chemical science holds in any way the same dominant position in didactics that it does in agriculture, we do find, even in the smaller institutions of higher learning, that, as a rule, chemical science is taught more thoroughly and more effectively than other branches. The consideration of these facts, if prominently brought before the attention of the public, would certainly do much to increase the estimation in which our profession is held.

The above only illustrates in one industry the dominant influence of chemical research, and in so far as science comes into direct contact with the industries of the world it is evident that in almost every one chemistry occupies the predominant position. This well-recognized fact is a firm basis for the substantial claims of the dignity of our profession.

There is one point, however, in which it seems to me we are much at fault, and that is in the fact that the chemists of this country seem to have taken but little interest in the science of civics. We are too prone to regard politics as a profession beneath the dignity of a scientific man, and yet we must admit that the organization of the body politic for the public good is the highest work to which a man can devote himself. In other words, real politics is the most useful and most honorable of professions. The trouble here in this country is that politics becomes too much of a profession. In other words, it becomes a source of revenue or of sole revenue. How much better it would be if men who have reached success and competence in other professions, without abandoning these in their maturer years, would devote a portion of their time to the public good. In Europe this is commonly the case and we are all familiar with the names of eminent scientific men who have become celebrated also as leaders in political life. In Germany, we recall the name of Virchow, who, for more than thirty years, has been a member

of the National Legislature, and of Mommsen, the great historian, who has taken an active part in politics. In Italy, one of the honorary members of our society, Cannizaro, is a senator and vice-president of that body. In France Berthelot is a life senator and has been minister of foreign affairs. In England, Roscoe has been a member of Parliament and Faraday and Humphry Davy and other scientific men were active in public affairs. In our country, I believe, only one member of the Chemical Society has ever become a member of the National Legislature and this was due to a fortuitous combination of most incompatible elements, namely, a union of democracy and prohibition.

I think we should all strive to discourage this sentiment, which is so prevalent, that politics is a dirty pool and that men of science should keep out of it. When you have reached competence and distinction in your profession what better service to which to apply your leisure hours than the study of the public weal? There are so many ways in which science can be utilized in political and civic affairs. The conservation of the public health, the prevention of epidemics and contagious diseases, the control of the water supply of cities, the disposal of the refuse of cities, the study of dangerous and fraudulent counterfeits of foods, are all matters affecting directly the public health and the public welfare. To become interested in these matters would be to more actively participate in public affairs, and it seems to me it is an ambition which every scientific man might well entertain, not only to become eminent in his profession, but also to devote a portion of his more mature life to the study of the public welfare and the active participation in those political relations of life which will enable him to become more useful to humanity.

May we not then expect to see the day when our State and National Legislatures shall not be considered as properly organized until they have among them members representative of the great body of American chemists?

On April 12, 1976, will be celebrated the centenary of our society and shortly thereafter the bicentennial of our national independence. May I drop for a moment the rôle of chemist and assume that of prophet? Our country will have then about 225,000,000 inhabitants. Our foreign export trade will amount to more than $500,000,000 annually. The revenues and expenditures of our Government will each reach the annual sum of $4,000,000,000.

The average yield of wheat in the United States will be nearly 25 bushels per acre, and the average yield of other field crops be proportionately greater than now.

Diversified manfacturing industries will flourish in every part of the country, thus distributing population and encouraging agriculture. The product of a day's labor will be double that of to-day, thanks to new processes, improved machinery and greater skill. The condition of the artisan and the laborer will be greatly ameliorated, and the principles of the trust, which now help chiefly the capitalist, will be extended to include the working man as well. The laborer will not only have a larger daily wage, but will also share in the legitimate profits of the business.

The advancement of chemical science will not only make the fields more productive and more easily tilled, but will also teach how their products can be more economically and easily consumed. Good roads will lead everywhere and the horse be relegated to the museum and the stable of the sportsman. New sources of energy will take the place of coal and gas, and this energy will come from the winds and the rains. The sun directly and indirectly will monopolize the power of the country, working

through evaporation and precipitation and by means of electricity or some more useful force.

By a general comprehension of the principles of nutrition, food will be more wholesome and more potent. The general acceptance of the principles of hygiene will make the average life of man longer and his usefulness more fruitful. Man will not only live longer, but he will be happier and practically free from the threats of enzymic, contagious and epidemic diseases. When this Society meets on that founders' day, the membership will be nearly 10,000 and its organization will reach to all quarters of our imperial country. The number of those who to-day are members and who shall live to 1976 is not large, possibly *nil*, but many who are infants to-day will be the revered old men on that centennial occasion. The orator who will address you on that day is perhaps not yet born. I hope he will take for his theme, the 'relation of chemical work to the advancement of mankind in the past century.' He will find in the development of some of the thoughts which I have tried to bring to your attention to-night the most potent causes that make for the good of man. In such a light as he can shed on life and its conditions the coming man will be able to see the true dignity of chemistry. H. W. WILEY.

U. S. DEPARTMENT OF AGRICULTURE.

DIAMOND-GLASS FLUORESCENCE.

SOME five years ago I had occasion to cut a large number of photographic dry plates to smaller sizes. They were cut in the usual way—with a diamond and on the side of the plate opposite the film. In developing it was noticed that the film, to a breadth of a few millimeters along the edge of the plate, turned dark as if exposed to light.

Several possible explanations suggested themselves.

1. The breaking of the glass might produce momentary fluorescence and a fogging of the film near the break.

2. The breaking or tearing of the film might result in some sort of change in its character.

3. The scratching of the diamond might set up mechanical disturbances or vibrations in the glass and these might affect the film.

4. The friction between the diamond and the glass might cause a momentary fluorescence along the line traced by the diamond, and the radiation might penetrate the glass and fog the film on the other side.

The first and second suggested explanations were thrown aside at once, for the dark band in the film was found along the diamond scratch, whether the plate was broken or not.

That the third is not the true explanation was shown in several ways. The breadth and density of the dark band did not appear to depend upon the depth of the cut or the rapidity with which it was made. The line was always of about the same breadth on the same plate, but of different breadths on different plates. Moreover, the film always developed first on the side next the glass. The effect was noticeable on the most sensitive plates only.

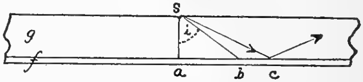

fig 1.

Let f represent the film on a section of the glass plate g, perpendicular to the diamond scratch s. Let s be a source of radiation.

All rays (as sc) outside the critical angle i are totally reflected and hence do not affect the film. Those having an incident angle smaller than i penetrate the film and

fog it, if they are of sufficient intensity. The breadth of the fogged line is

$$b=\overline{2a\,b}=2\,t.\tan i$$

where t is the thickness of the glass plate and i is the critical angle for glass and the film substance. Using plates of different thicknesses, it was found that, in every instance, b varied as t to the degree of accuracy with which the measurements could be made. When a clear glass plate was laid on the dry plate, scratching the upper plate gave a band whose width varied as the combined thickness of both plates. If, however, the dry plate were turned over so as to have the film between the plates, the breadth of the band varied as the thickness of the upper plate. And in this case when the plate was placed in the developer, the band appeared first on the outer or upper side of the film.

It was found that fluorescence does not always occur when a diamond is drawn over a dry plate. Different diamonds and different brands of plates (glass) gave different results. To determine the cause of this apparent irregularity I made a series of observations, using ten different diamonds and nine kinds of plates. Seven of the diamonds were ordinary glass cutters, ranging in size from a very small stone in No. 1 (see table) to a large stone in plate glass cutter No. 7. Nos. 8, 9, and 10 were Brazilian black diamonds (in emery wheel cutters) known as carbonadoes. They appeared to be amorphous.

Ordinary plates, even the most sensitive, were not very sensitive to this fluorescence. Cramer, Stanley, Seed, Carbutt and Hammer plates were tried. Sometimes the diamond produced a slight fogging; usually it did not. In this respect no constant difference was noted in the different brands of plates.

To determine whether the quality or nature of glass influences fluorescence I asked the M. A. Seed Dry Plate Co. to supply me with plates of different kinds of glass coated with the same emulsion. The Company informed me that they were using four brands of glass, English, French, white crystal and American, and they sent me a supply of each kind coated with their most sensitive orthochromatic emulsion.

Their orthochromatic plate (No. 27) was found to be much more sensitive to diamond-glass fluorescence than the most sensitive ordinary plate. Fogging almost always occurred along the diamond trace, and the dark band was frequently very dense.

The following table embodies the results of the tests of different glass with different diamonds:

TABLE I.

Diamond.	Seed's orthochromatic plates, No. 27.				Seed's ordinary "Gilt Edge."	Total.
	English glass.	American.	French.	White Crystal.		
1. Small	trace 1	weak 2	trace 1	weak 2	absent 0	6
2. "	strong 4	absent 0	absent 0	weak 2	absent 0	6
3. "	strong 4	weak 2	trace 1	fairly strong 3	trace 1	11
4. Medium	strong 4	fairly strong 3	weak 2	fairly strong 3	weak 2	14
5. "	trace 1	trace 1	absent 0	weak 2	absent 0	4
6. "	trace 1	absent 0	absent 0	trace 1	absent 0	2
7. Large	trace 1	trace 1	absent 0	absent 0	absent 0	2
8. Carbonado	absent 0	absent 0	absent 0	absent 0	absent 0	0
9. "	absent 0	absent 0	absent 0	absent 0	absent 0	0
10. "	absent 0	absent 0	absent 0	absent 0	absent 0	0
Total	16	9	4	13	3	

Representing by numbers the relative intensities of the fogged bands, any total in

the last column is obtained by adding the intensities for the five kinds of plates and a single diamond. Similarly the last row represents the intensities corresponding to all the diamonds and one kind of glass. The table shows that the fluorescence depends upon the kind of glass, and also upon the particular diamond used. One would expect the former, and one might not be surprised that the black amorphous diamonds do not act as do the clear crystalline stones. But that the latter differ among themselves is strange. It was thought that the difference might be due to differences in shape and the character of the scratch. This conclusion was rejected when it was found that diamond No. 4 would always fog the plate, even when the surface of the plate was not scratched at all. When the diamond was held out of cutting position and drawn across a plate, a dark band appeared on development. Diamonds Nos. 5 and 6 could scarcely be made to fog a plate, however they were held.

That friction has much to do with fluorescence was shown by the fact that sometimes a dark band would be discontinuous in two or three places along a diamond scratch.

The band produced by No. 4 was so strong that it was thought the fluorescent light might be visible. This proved to be true. When the eye was rendered very sensitive by being in absolute darkness for an hour, the conclusions drawn from the table were verified directly. The fluorescence from No. 4 was very marked, especially when English or white crystal glass was used. No visible fluorescence could be obtained with any of the black diamonds.

To test the equation $b=2t.\tan i$ a dry plate was laid on a table, film upward. A plate of clear glass was then laid on the dry plate and a diamond was drawn across the clear plate. The mean of several measurements of b and t gave a critical angle of about 39°. For the particular plate used, this was approximately the critical angle for yellow light, showing that, whatever other wave-lengths might be present the longest waves that affected the film were those of yellow light. This conclusion was strengthened by the fact that, to the eye, the light appeared to be a greenish yellow, and that orthochromatic plates were much more sensitive to it than ordinary plates.

Measurements of b and t for plates of various thicknesses gave values of i ranging from 38.6° to 40.4°. It would seem that the fogged band should be much broader when the dry plate itself is scratched, for then the critical angle is determined by the ratio of the indices of refraction of gelatine and glass. Measurements did not confirm this point, though they showed a constant ratio between b and t.

ARTHUR L. FOLEY.

PHYSICAL LABORATORY,
INDIANA UNIVERSITY.

HOW BOTANY IS STUDIED AND TAUGHT IN JAPAN. *

MODERN botany was practically introduced into Japan twenty-four years ago by the late Professor Yatabe,† who studied botany at Cornell University, graduating in 1876. He became the first professor of botany at the Imperial University of Tokyo. Before him there were several botanists in Japan who studied the native plants quite thoroughly. But most of them being amateurs, did not know much about modern botany. Some of these old botanists still live. The well-known Dr. Keiské Ito, who was the Director of the Botanical Garden of the University before Professor Ya-

* A paper presented at one of the Botanical Seminaries, Cornell University, November, 1900.

† Professor Yatabe was drowned in the sea at Kamakura not far from Tokyo in August, 1899.

tabe, still lives, being in his ninety-eighth year.*

A short sketch of his life, with a portrait, by his grandson Dr. Tokutaro Ito appeared in a late number of *Annals of Botany.* †

Professor Yatabe paid especial attention to systematic botany. Soon after his return from America he began to make a large and extended collection of the native plants, making long expeditions, especially in the summer vacation. It is to his arduous labors in collecting that the larger part of the herbarium of the Imperial University is due. He found and described many plants new to science. But his contributions are rather local and quite hidden from the general notice of many botanists. It is indeed only during the last few years that Japanese botanists have begun to contribute more or less to the general progress of the science.

I will now relate how botany is taught in the Imperial University of Tokyo. Before doing so, it is necessary to say how one must prepare before entering the University. A child goes to the common school at the age of six and remains there for from six to eight years before entering the high school. In the high school, English, mathematics, history, geography, physiography, physics, chemistry, zoology, botany, physiology, mineralogy, together with some Japanese and Chinese literature, are taught. This takes five years. English is the only foreign language taught in the Japanese high schools, except in one school in Tokyo where German is studied instead of English. This is the preparatory school for the medical department of the University.

If one wishes to enter the University one must spend three years after graduating from the high school in the higher high school (Kōtō gakkō). In the higher high school three different courses are given.

*Since this paper was read Dr. K. Ito has died (Jan. 24, 1901).

†Vol. XIV., No. 55, Sept., 1900.

The first course is required for the students of law and literature; the second is required for the students of science, engineering and agriculture, and the third for the medical students. The students of medicine are separately educated, as it is necessary for them to be thoroughly acquainted with German. In these three courses further subdivisions are made, according to the specialty of the student. If he is a student of botany, he is required to take the second course and to study botany, zoology, physics, chemistry, geology, mathematics, English, German, sometimes French or a little Latin, besides some Japanese and Chinese literature. After graduating from the higher high school he is admitted to the University without examination.

There are now two imperial universities in Japan, one in Tokyo and the other in Kyoto, the old capital of Japan. The latter was founded only three years ago and contains now the Colleges of Science, Engineering, Medicine and Law. No botanical department is yet established.

The Imperial University of Tokyo is divided into six colleges or departments: the Colleges of Science, Law, Literature, Medicine, Engineering and Agriculture, the last including Forestry and Veterinary Medicine. The College of Science is further divided into seven departments. These are physics, chemistry, mathematics, astronomy, zoology, botany and geology. All the courses of the University are required except a very few elective ones. Usually it takes three years to graduate, but in the departments of Law and Medicine four years are required.

The students of botany are required to study zoology, including histology and embryology, geology, paleontology, mineralogy, physiology, physiological chemistry and bacteriology, besides botany. In the first year they have three lectures a week on general botany (morphology and physi-

ology) besides three laboratory hours. The laboratory work begins in identifying the various common plants, making drawings of each. In this work Gray's 'Manual', or 'School and Field Botany,' is often used, as we have no complete manual of Japanese botany. Next comes the gross and minute anatomy from the lower to the higher plants. Especial attention is paid to the various kinds of tissues, often referring to the comparative anatomy and development, together with some microchemical reactions of more common cell-contents. In the third term especial attention is paid to fertilization, embryology and development. The fern and *equisetum* are studied from the germination of the spore to the formation of sexual organs on the prothallia. The fertilization of pine and *gingko* affords good objects for study. Cell-divisions are often studied with the root-tip of beans, pollen mother cells of *Tradescantia*, lilies, etc.

In the second year three lectures on systematic botany are given weekly and three laboratory hours are devoted to plant physiology throughout the year. Various experiments on carbon assimilation, respiration, transpiration, geotropism, heliotropism, rheotropism, hydrotropism, etc., are made. Growth is observed with various auxanometers and horizontal microscopes. Then micro-chemical studies of various important cell-contents, including the inorganic salts are made. Their distribution and the transformation within the plant bodies are then studied. Artificial pure cultures of various algæ, fungi, bacteria and yeast are made, paying special attention to the nutrient value of various organic and inorganic compounds. Water cultures of the higher plants are also made. Chemotropism of the pollen tube, fungal hyphæ and chemotaxis of bacteria are carefully studied. Regeneration of the liverwort thallus and the dandelion root, nodal growth of Gramineæ are the other objects of study. *Tradescantia* cell with its red-colored sap affords excellent material for studying the osmotic pressure in the cell. Isotonic coefficient of various organic and inorganic substances are determined according to the method of de Vries. In the third term, sometimes a special subject of study, being either original or a repetition of the previous work, is given to each student.

In the third year the only required studies are: one hour's lecture weekly on plant physiology during the first term, and one lecture and two laboratories on bacteriology during the second term. The rest of the time is spent in the work of graduate theses. Subjects of theses are mostly physiological or anatomical. Following are the subjects of theses presented to the University by the graduates in botany in the last three years:

1898.

T. Inui. 'Anatomy and physiology of the gum-resin duct of lac-tree and the other species of *Rhus*.' (English.)

1899.

K. Shibata. 'Contribution to the physiology and anatomy of bamboo.' (German.)

N. Ōno. 'On the acceleration of growth in some algæ and fungi by chemical stimuli.' (German.)

H. Hattori. 'Studies on the action of copper sulphate upon plants.' (German.)

S. Kusano. 'On the transpiration of evergreen trees during winter in middle Japan.' (English.)

K. Miyaké. 'On the carbon assimilation of evergreen leaves in Tokyo and other parts of Japan during winter.' (English.)

1900.

K. Saitō. 'Anatomical studies of Japanese fiber plants.' (German.)

Y. Yabé. 'A revision of the Umbelliferæ of Japan.' (Latin.)

The chief results of the above-mentioned

theses, except that of Mr. Yabé, are already reported in the *Botanisches Centralblatt*,* by Professor Miyoshi. Some of them have already been published, and the rest will be published soon.

In the graduate course no lectures are given. By presenting a thesis which represents five years' study after graduation the degree of 'Rigaku hakushi' (Doctor of Science) is given. Of these five years the first two must be spent at the University. There are now seven students in the graduate course of botany, one of them studying outside of the University. Their subjects of study are mostly in the lines of plant physiology and physiological anatomy.

At present there are two professors and three assistants in the Botanical Department. Professor Matsumura, who is the head of the department and the director of the Botanical Garden, has charge of systematic botany. He studied in Germany under the late Professor Sachs, in Würzburg, and Professor Pfitzer, in Heidelberg. Professor Miyoshi is the professor of plant physiology. He graduated from the Imperial University and afterward studied in Professor Pfeffer's laboratory at Leipzic for three years. He is the well-known worker on the chemotropism of fungi.

Professor Matsumura is now studying the flora of the islands of Formosa. The results of his study have been partly published. Professor Miyoshi is engaged in investigating the coloring matter of flowers, besides other physiological studies. Mr. Fanjii, the assistant, who has occupied this position for several years after graduating from the University, is making researches along morphological and ecological lines. Mr. Makino, an assistant, is now studying the difficult group of bamboo, besides his systematic researches on Japanese phanerogams and ferns.

* *Botanisches Centralblatt*, Bd. 80, No. 5, 1899, and Bd. 83, No. 11, 1900.

The Botanical Laboratory is situated in the Botanical Garden. The Botanical Garden is more than two hundred years old. The garden was used primarily for medicinal plants, but now it has many kinds of Japanese and foreign plants. There is also a large green-house. The herbarium of the Botanical Laboratory contains nearly all the Japanese plants, including tropical plants from the islands of Loochoo and Formosa, besides some exotic plants. The cryptogamic herbarium is not yet completed, as many of the lower forms are not well studied. The library of the laboratory contains the leading German, French, English and Italian journals. Zeiss microscopes are commonly used in the laboratory.

There is another botanical laboratory in the College of Agriculture. Professor Shirai has charge of plant pathology and dendrology. He is especially interested in fungi and the plant diseases. He is now studying in Berlin. Professor Ikeno, the well-known investigator of *Cycas*, is giving the lectures on plant morphology and physiology. He is engaged on investigations in histology and cytology. The leading English, German and French botanical journals are also found in this laboratory.

The botany in the higher high school in Tokyo is taught by Dr. Goto, who is a zoologist. In the Higher Normal School of Tokyo, Professor Okubo has charge of the Botanical Laboratory. Professor Miyoshi, of the Imperial University, is now giving the lectures on plant physiology during the absence of Dr. Saida, who is in Germany.

In the Agricultural Experiment Station of Tokyo there are several botanists. Mr. Hori, the chief botanist, has charge of vegetable pathology. Various kinds of plant diseases are constantly studied here. The disease of the mulberry tree, the leaves of which furnish the food for the silkworm, were the special subject of investigation during the last few years by a special com-

mittee. The cause of the disease is found to be physiological, not caused by any organism, as it was thought before. A remedy for the disease is still being investigated.

There are several botanists in Tokyo outside of the above-mentioned institutions. Dr. Okamura, who is the lecturer of the Fishery Institute of the Government, is making continued studies on the marine algæ of the Japanese seas. He has just issued the first fasciculus of his 'Algæ Japonicæ Exsiccatæ,' which contains fifty species. Dr. T. Itō, who studied botany at the University of Cambridge some fifteen years ago, is making extensive systematic studies on the flora of Loochoo islands. A part of the work was published in a late number of the Journal of the College of Science, Imperial University of Tokyo.

The works of the Japanese botanists are often published in the Journal of the College of Science, Imperial University of Tokyo, as well as in the leading foreign journals. The shorter papers appear in the *Botanical Magazine*. The magazine is published monthly, partly in Japanese and partly in the European languages. It is the organ of the Tokyo Botanical Society. The Society has about three hundred members, living in various parts of Japan. Among them we find many high and common school teachers. There are two series of small pamphlets published monthly with figures and descriptions of Japanese plants. One contains figures, with brief descriptions and remarks of the flowering plants and ferns of Japan. The other contains those of the lower cryptogams. The illustrations and descriptions in the former are made by Mr. Makino. The latter is contributed to by many Japanese botanists and edited by Professors Matsumura and Miyoshi.

A still larger work on Japanese botany has just begun to be published. This is the 'Icones Floræ Japonicæ,' a large-sized pamphlet with minute and careful drawings and descriptions of Japanese plants, compiled by the Botanical Department of the University. Volume I., Part 1, has lately been published. Mr. Makino is now engaged on the work. All the drawings and descriptions are made by his own hand.

In closing I must not neglect to make a brief statement of the Botanical Laboratory in the Agricultural College of Sapporo far north in 'Hokkaido,' the Yezo Island. The director of the Botanical Laboratory and the Botanical Garden is Professor Miyabé. He studied at Harvard University some ten years ago. The herbarium of the Laboratory has a complete set of the plants of the Yezo Island, besides other Japanese and foreign plants. Professor Miyabé is interested in fungi and plant diseases. Several works in this line have been done both by him and by his students. Professor Miyabé also studied the Laminariaceæ of the northern seas. Two new genera have been established by him in this single family.

Japan is a long country, though narrow, extending from 51° north to the tropics. The variety and richness of the flora are incomparable. Though the phanerogams and the ferns of the empire are pretty well known, many lower cryptogams have not been thoroughly investigated.

SCIENTIFIC BOOKS.

Reservoirs for Irrigation, Water Power, and Domestic Water Supply. By JAMES DIX SCHUYLER, M.Am.Soc.C.E., etc., etc. New York, John Wiley and Sons, 1901. \$5. Pp. xvi + 414. 174 figs., with maps and appendix.

The subject of reclaiming by irrigation the extensive arid tracts of western North America is pressed upon the attention of the general public, and also upon that of the engineering and financial world, with increasing emphasis from year to year. Private capital is urged to

provide reservoirs and irrigation works and has already done so to some extent, and the question of aid from the national government in extending the work is under debate. Much light is shed upon what has already been done in this direction, as well as upon what is proposed and is under way, by Mr. Schuyler's interesting book, which embodies the material used in his reports to the U. S. Geological Survey in 1896 and much additional matter of more recent date.

The book is unquestionably a valuable one for civil engineers, giving, as it does, a description of the principal dams built, and now projected, in the western portion of the United States; and also some account of large dams in foreign countries, already completed or in progress, such as those at Assuan and Assiout in Egypt; giving also (to quote from the title page), "A discussion of the available water supply for irrigation in various sections in arid America; the distribution, application, and use of water; the rain-fall and run-off; the evaporation from reservoirs; the effect of silt upon reservoirs," etc. In some cases details are presented in great fullness; and illustrations, views, profiles, maps and plans occur in profusion throughout the work, thus greatly enhancing its value. As an instance in point, it may be noted that in the description of the Sweetwater dam, in southern California, built after the design, and under the superintendence, of Mr. Schuyler himself, there are fourteen distinct illustrations (views at different stages of construction, sections, maps, etc.), the description itself occupying seventeen pages.

This same dam offers a striking instance of the benefits obtained by the erection of such a structure. During the thirteen irrigation seasons up to 1900 'the impounded water has created values aggregating several millions of dollars, reckoning all improvements made in the district directly dependent on it for water supply.' Domestic water supply is also furnished to a population of from 2,500 to 3,000 people. The cost of the dam was $234,000 and the area at present irrigated from it is 4,580 acres.

The dams described are classified according to their mode of construction and may be briefly referred to as follows:

'*Rock-fill*' dams are composed of stones deposited loosely together in a trapezoidal form, water-tightness being provided by a sheathing of plank on the upper side, or by an earth facing. This plan originated some fifty years ago in the mining regions of California, when the transportation of cement into remote districts was very expensive, or impracticable. Later construction employed a concrete 'skin' on the upper side; or a central and vertical steel plate, covered on both sides with hot asphalt and burlap, and then imbedded in a wall of concrete. Sometimes the steel plates formed a facing on the upper side.

The '*hydraulic-fill*' dams were composed of earth and gravel deposited by 'sluicing' the material into position; that is, by washing down the soil by jets of water from higher elevations in sluices or pipes into the desired position. In this way, by proper management, the finer soil could be made to occupy the center of the dam or embankment, while the coarser gravel and stones formed the outer portions; and extreme cheapness of construction was often attained. Thus, the Tyler dam, in Texas, 575 ft. long and 32 ft. high, cost only $1,140; including the expense of pumping water to form jets for loosening and sluicing the soil. As the water drains off gradually the gravel, sand and clay are more compacted, it is claimed, and hence a more water-tight dam obtained, than if the material had been laid dry and then tamped.

Naturally, the chapter on the masonry dam, as being the most durable and stable construction, occupies a greater space in the book than any other. Here the usual arguments are presented in favor of the gravity dam, as against the horizontal arch; though the curved form is advocated in certain cases for esthetic reasons, and as providing for remote contingencies. A full description is given of that 'eighth wonder of the world,' the noted Bear Valley dam, in California, which with its very slender dimensions depends for stability solely on its arched form; this form having been given to it to effect a saving in the cost of masonry, since the cost of hauling cement to the locality was at that time (1884) $10 per barrel. The Sweetwater dam, already mentioned, belongs to this

class and was built in 1888. An interesting fact with regard to sedimentation in this reservoir is that during the twelve years of its use the bed of accumulated silt in the deepest part (some 90 ft.) was only 3 ft. in thickness. This is in great contrast with the rapid silting of Lake Macdonald, the reservoir created by the Austin dam of Texas, whose design and construction, and also final failure in April, 1900, are described by Mr. Schuyler.

Concrete dams are next taken up, including the structure of that type built for the Hydraulic Laboratory of Cornell University; in connection with which an account is given of the device adopted for 'concentrating the contraction due to temperature changes in the concrete to a central point of weakness.' The resulting fissure was filled up in cold weather and continuity thus secured.

In the chapter on earthen dams mention is made of the ancient 'tanks' or storage basins, of Ceylon, one of which was closed in by an embankment 11 miles in length and 200 feet high; also of several in India. The other earthen dams mentioned are in Colorado and California, one of them (5.5 miles in length) serving to close in the Buena Vista Lake Reservoir, which has great extent (25,000 acres) but is only about 7 feet deep. As a result of this, the annual loss of water by evaporation is estimated at 70 per cent. of its capacity. However, when the evaporation is most active, the loss is made good continuously by the influx from the river.

The Ash Fork steel dam in Arizona, described on p. 222, was erected in 1897 and is an unusual construction, consisting of a number of vertical steel frames or trusses, connected or 'bridged over' at the upper side by curved plates of steel which form a continuous and water-tight covering. The structure is 33 feet high, 184 ft. long, and cost $45,000.

Natural reservoirs are next mentioned; *i. e.*, ready-made reservoirs or depressions, waiting only for water to be turned into them from neighboring streams of sufficient elevation and for suitable provision for its regulated escape.

The last chapter, on 'Projected Reservoirs,' is of considerable length and full of detail, treating of many irrigation surveys and projects for impounding water, throughout the Western States and Territories. Several of the structures mentioned are already in process of construction. An appendix of various tables made for the U. S. Geological Survey, and contoured maps of reservoir systems, complete the work.

A very commendable feature of Mr. Schuyler's book, and one that will be appreciated by civil engineers, is the information given as to the *cost* of many of the dams and other structures described in the work.

I. P. Church.

Annual Reports of the War Department: Report of the Chief of Ordnance. Washington, Govt. Print. 1900. 8vo. Pp. 474. Numerous appendices and plates.

The reports of the War Department always contain much of interest to the general reader and to the thoughtful citizen, apart from their purely technical matter, as, for example, the accounts of work performed under the River and Harbor Bill. Those of the Chief of Ordnance are particularly interesting to the student of metallurgy and to the engineer as giving much valuable information regarding materials. Occasionally a side-light is thrown upon interesting phases of governmental and official administration; as where the report of the chief of a bureau permits the reader to see the hand of the politician in the determination of the location of important locks, in river improvements in the West and the reason for the displacement of a worthy and capable officer insisting upon correct business methods, or where, as in the report before us, the official documents reveal the fact that a Committee of Congress, composed mainly if not entirely of non-experts, or amateurs at best, decides to 'try an experiment' with Government funds, to the extent of many thousands of dollars, directly against the expressed opinion of the official expert advisers of the Department and of Congress, or where official and expert authorities are permitted to be accused of refusing to permit the civilian expert reasonable opportunity to display his talent, and the charge is left without complete and decisive investigation and report. Amateurism is not altogether a monopoly with departments.

The Report of the Chief of Ordnance, proper, is a very brief, business-like and well-condensed summary of the operations of the bureau for the fiscal year ending June 30, 1900, covering 42 pages of the volume. The details of the work are exhibited in the remaining four hundred pages, in which are given forty appendices, mainly reports of officers charged by the Bureau with important duties and including the operations of the various arsenals.

Watervliet Arsenal, for example, has turned out during the year 45 ten- and twelve-inch rifles and mortars, and five smaller rapid-fire guns, and has made a large quantity of accessory material. Springfield Armory made about 60,000 army rifles and carbines and attained an output of 400 guns a day. Working eight hours a day, it now turns out about 200. As usual, a large amount of experimental work has been performed. Watertown Arsenal has been engaged upon sea-coast gun-carriages and its great testing-machines—it now has one of 200,000 pounds capacity, in addition to the older machine of 80,000 pounds—have performed a considerable amount of valuable scientific work in addition to that of the routine operation of the Department. Frankford Arsenal has made, during the year, 23,000,000 small-arm cartridges and can now issue about 90,000, per day of eight hours, continuously. Rock Island Arsenal turns out most of the infantry and cavalry equipments of the army. It makes blanket-bags at from $1 upward, haversacks at from 85 cents, canteens at 32 to 38 cents and tin cups cost but 10 cents to make. Costs have come down and wages gone up with the use of improved machinery. A new small-arms factory is under construction here, to produce 200 to 250 guns a day. Heavy guns for fortifications have been so extensively supplied that the Department is now turning its attention to the smaller rapid-fire guns. A muzzle velocity of 3,000 feet per second is to be attained in the later construction.

Wire-wound guns continue a subject of experiment, but still without complete success. It has come to be a question whether the disappearing gun-carriage for heavy mounts is best practice and whether it has not been too exclusively adopted. The Bureau does not express a decided opinion on this point. The automatically operating rapid-fire gun is reported upon and recently invented automatic pistols are the subject of investigation, with the result of choice of the Colt construction for army use, if later approved by the Department.

Interesting investigations of the composition of acceptable gun-steels give the valuable deduction that for an elastic limit of 70,000 to 75,000 pounds per square inch, and a tenacity of 100,000, with an elongation 15 to 20 per cent., the compositions should include about one-half of one per cent. carbon, one per cent. manganese, one-fifth to one-tenth per cent. silicon, and well under one-tenth of one per cent. of sulphur or phosphorus. Oil-tempering is not of advantage. Rolling is best performed at a temperature a little way below that of the blue 'critical heat.' One curiously interesting deduction is that the action of smokeless powder, or other high explosive, attaining a given pressure in the barrel of a gun, is less destructive than a similar pressure produced by ordinary static testing. The duration of the pressure is about 0.0004 second only, and time is thought to have an important influence upon results. The normal powder pressure in the army rifle is about 42,000 pounds per square inch. The singularly interesting phenomenon, extensively investigated by the writer many years ago, 'the exaltation of the normal elastic limit by strain,' * finds application here, as in so many other matters of applied science; the practice being now established of rolling and forging parts at a minimum temperature to insure high elastic limits and maximum tenacity.

R. H. THURSTON.

Experimental Psychology. A Manual for Laboratory Practice. By EDWARD BRADFORD TITCHENER. Volume I. Qualitative Experiments; Part I. Student's Manual. Pp. 214. Part II. Instructor's Manual. Pp. 456. New York, The Macmillan Co. 1901.

The place of laboratory practice in the teaching of psychology has, in American universities at least, become assured. It is by no means

* *Trans.* A. S. C. E., 1873. 'Materials of Engineering,' Vol. II., Chap. X.; Vol. III., Chaps. XIII., XIV.—R. H. T.

settled in method, mode of instruction, arrangement of the work, or indeed of the principal aims to be accomplished. There has been too little time for any usage to become traditional or classic; and individual solutions of the important as well as of the incidental problems have been the unavoidable rule. Such usage is likely to become established through the influence of laboratory manuals more easily than through any other source. Sanford's manual is the pioneer in this field, and has been available in various stages of incompleteness for five years or more. Cattell maintained an attractive announcement in a publisher's list for some years; but this was withdrawn on the publication of Sanford's book. Scripture has published some helpful notes on the conduct of experimentation in the psychological laboratory; Höfler and Witasek have recently published a book of *Schulversuche;* and other sporadic contributions to special parts of this topic may be found by the industrious seeker. Professor Titchener's volumes form a weighty addition to this small group of pedagogical aids, and one certain at once to take high rank and to have an important part in the shaping of experimental usage in psychology.

The plan of the work covers two volumes; the first devoted to qualitative experiments, the second to quantitative experiments. These, again, will appear in two forms; the one for the students and the other for the use of the teacher. The present two volumes include the qualitative experiments for the student and for the instructor. It is, therefore, as yet premature to judge of the scope of the completed work; but the architectural principles upon which it is reared are sufficiently represented in this first portion to enable one to intelligently estimate the place which the whole is to occupy in the literature of psychology. The student's manual proceeds, after a brief introduction on the general arrangement of experimentation, to consider sensation (six chapters, including the five senses and organic sensation), the affective qualities, attention and action. Then follows a consideration of the rôle of perception, and the association of ideas—falling into chapters on visual space perception, auditory perception, tactual space perception, ideational type and the association of ideas. This range of matter is grouped in thirty-seven experiments, many of them rather complex in character and involving a considerable number of separate observations. The experiments are clearly and suggestively elaborated, the instructions lucid, the emphasis laid on the interpretation of the results commendable. There are numerous illustrations, and the mechanical features of the volume leave nothing to be desired. The work represents the result of many years of experience of an experimental psychologist who emphasizes, as markedly as any of his colleagues, the importance of laboratory practice, and has evolved for his own use as comprehensive a system as is in vogue in any laboratory of psychology. The scholarly character of the result, the authoritativeness of the positions therein embodied, are unmistakable. Every director of a laboratory of psychology, small or large, will find much direct aid and more indirect suggestion in this newest manual.

The central question, upon which there is likely to be a marked difference of opinion, relates to the plan of the work and its adaptability to the several needs and facilities of the university and college courses in psychology. The division of the work into a qualitative and a quantitative part is evidently fundamental in the author's conception. Sanford's manual combines the two in a serial treatment of topics. How the two camps will divide it is not easy to foresee; for though we may hold that pedagogy is a science, it does not give unambiguous answers to such queries. The analogy to chemistry is at once suggested. But in chemistry there is in the main only a repetition of the one analysis with added mathematical factors; this seems hardly the case in psychology. The separation of the two in chemistry introduces no sense of incompleteness; and for introductory instruction, the one has a traditional and well-founded prestige. Neither fact is true of psychology. The practical question of economy of time and advantage in going over the ground once qualitatively and again quantitatively will deter many from introducing this practice even if they favor it upon logical grounds.

The present writer, after weighing the pros and cons both of a theoretical and of a practical

sort, must decide for his own part in favor of a topical treatment in which qualitative and quantitative analyses are conjointly used and regarded as methodical aids to the elucidation of principles and the determination of results. As in physiology we consider first the bony system, then the circulatory, then the nervous system, and so on and in the end and all the way through keep in mind the mutual interrelations of these systems, and introduce quantitative determinations so far as they aid the comprehension of the functions considered; so in psychology there is good ground for considering that the greatest pedagogical success and the clearest insight into the significance of mental phenomena will be reached by the pursuance of a similar method of exposition. For those of this opinion, it will still be possible to use the qualitative and quantitative parts together, though with some readjustment of method. Another marked characteristic of the manual is the selection of a relatively few groups of experiments and the careful elaboration of these. In this an exemplar may be found in the usage of many laboratories of physics. In the unsettled status of psychological practice this point is also likely to be favored by some and rejected by others. The principle involved is this: How far shall an experiment represent a verification by each individual of the essential facts of a given principle or trait of mental processes? or shall it be a miniature reestablishment of the method and the evidence which led to the formulation of that principle? Sanford adopts the former plan, Titchener the latter. Again, both practical and theoretical considerations will affect one's decision; that the former practice is the more readily assimilated to the ordinary practice courses of our universities admits of little doubt. These, then, are some of the differences of route which the psychological tourist will encounter; and he must choose his own guide and take the benefits and losses that result from his choice. Which is the easier road to travel, which affords the better outlook, experience alone will decide. It is fortunate that our psychological guides, in this case, are animated by the best of motives and equipped with admirable training for their tasks.

Both Sanford's and Titchener's manuals are adapted to the student with a marked and well-grounded interest in the work. They are manuals for 'long course' specialized students. There is still an urgent need for a more elementary manual that will cover a small number of carefully selected experiments in a way suited to the 'short course' students. Such seems to have been promised by the announcement which Cattell withdrew, and is in a measure accomplished by the German manual above referred to, and may be approximated by a judicious selection and reconstruction of Sanford's experiments. While welcoming a new and important aid to the teaching of experimental psychology, this need, that is still to be satisfied, may be appropriately noted.

The instructor's manual is a complete innovation in the literature of psychology, and one to be highly valued. It is to be understood that this is an entirely different book from the other, though necessarily following the same order of experiments and the same unfoldment of topics. Yet the text is addressed to the director of the experiments; he is given a complete account of the sources of error, and the precautions to be followed in the conduct of the experiment, is referred to the appropriate literature, and to more exact apparatus and observations not suited to student use. This, indeed, is in many ways the most valuable portion of the work. It makes possible for the first time the systematic training of the assistant by the director of the laboratory, and gives the special student in experimental psychology a reliable and methodical guide to the problems with which he is in the main to be concerned. The use of this manual as a basis of a special course for advanced students, in training to become professional psychologists, is one of its possibilities apart from its primary function. Professor Titchener has here placed at the disposal of his colleagues the result of years of very special and successful devotion to the problems of psychology susceptible to treatment by the experimental methods, and for this service so admirably accomplished he is entitled to the honors and privileges attaining to the distinction of carrying through so difficult and important a piece of pioneer work.

It is in the instructor's manual, likewise, that the spirit of the author's laboratory methods comes more clearly to the foreground. The presentation is more intimate, the descriptions more comprehensive, and the insight into the training which the course is intended to give more manifest. The genial set of instructions headed 'How to Fail in Laboratory Work,' might serve a good purpose if prominently exhibited in the laboratory. But the main point to be noted is the thorough appreciation of the fact that the psychological experiment carries with it its own conditions and peculiarities; that in becoming a 'subject' the individual retains all his peculiarities; and that these must be dealt with by tact and resource. The difference between good and bad observation upon mental matters depends upon this, almost equally with the acquaintance with method and technique. Both for the method and the matter, these volumes and the two to follow must be valued as amongst the most important of recent contributions to the furtherance of the aims of experimental psychology.

JOSEPH JASTROW.

Peach Leaf Curl: Its Nature and Treatment. By NEWTON B. PIERCE, in charge Pacific Coast Laboratory, Santa Anna, California. Bulletin No. 20, Division of Vegetable Physiology and Pathology, U. S. Department of Agriculture. Washington, Government Printing Office. 1900. Pages 1–204; plates I.–XXX.

A carefully detailed and exhaustive account of the geographical distribution, history, horticulture, botany and pathology of this destructive disease, and of experiments with the various remedies, methods and appliances for treating it. The most important of the conclusions is that very large percentages of the injuries due to the parasitic fungus *Exoascus deformans* are not caused by the renewed growth of perennial mycelium, but are the result of new infections occurring in early spring, and thus preventable by spraying the still unopened buds with Bordeaux mixture or other fungicides. Previous failures with such treatments are explained by the fact that the remedy was applied after the pathogenic organism had hidden itself in the tissues of its host.

As the annual losses from leaf curl in the United States are estimated at $3,000,000, the determination of these simple points is of great economic importance, and also of the widest interest, since this disease, unlike the yellows, extends to all regions where the peach is cultivated.

SOCIETIES AND ACADEMIES.

AMERICAN MATHEMATICAL SOCIETY.

A REGULAR meeting of the American Mathematical Society was held at Columbia University, New York City, on Saturday, April 27, 1901. About thirty-five persons attended the two sessions. Vice-President Thomas S. Fiske occupied the chair. The following persons were elected to membership: Mr. C. W. McG. Black, Yale University; Dr. S. E. Slocum, University of Cincinnati. Two applications for membership were received.

To relieve the increasing burden of administration, the office of Assistant Secretary was created and filled by the appointment of Dr. Edward Kasner, to serve until February, 1902.

The library of the Society, which at present consists mainly of some five hundred unbound volumes of journals received as exchanges, is about to be deposited in the library of Columbia University, under an agreement by which the University undertakes to bind, catalogue and care for the books now on hand and all future additions, and to make them easily accessible to the members of the Society. Arrangements will be made by which the books may be temporarily loaned to members living at a distance. The library is to be kept as a separate collection, duplicating as far as may be the general University library, and aiming to become as complete as possible in itself. The title to the books remains in the Society, which reserves

the right to withdraw them under agreed conditions.

The following papers were presented at this meeting:

Dr. W. A. GRANVILLE: 'Invariants of some m-gons under certain projective Lie groups in the plane.'

Dr. EDWARD KASNER: 'The algebraic potential surfaces.'

Professor F. MORLEY: 'On the real foci of algebraic curves.'

Mr. GEORGE PIERCE: 'A curious approximate construction for π.'

Professor E. W. HYDE: 'On a surface of the sixth order which is touched by all screws belonging to a three-conditioned system.'

Professor L. E. DICKSON: 'The hyper-orthogonal groups.'

Professor E. W. BROWN: 'On least action and minimal surfaces.'

Professor W. H. METZLER: 'On certain aggregates of determinant minors.'

Professor E. B. VAN VLECK: 'On the convergence of continued fractions in the complex elements; supplementary note.'

Professor W. F. OSGOOD: 'On a fundamental property of a minimum in the calculus of variations.'

Professor E. O. LOVETT: 'The geometry of quadrics.'

Professor E. O. LOVETT: 'The differential geometry of n-dimensional space.'

Dr. G. A. MILLER: 'On the groups generated by two operators.'

Dr. EDWARD KASNER: 'The relations between the angles of any number of lines in n-space.'

Dr. L. P. EISENHART: 'Isothermal conjugate systems of lines on surfaces.'

Dr. E. J. WILCZYNSKI: 'Geometry of a simultaneous system of two linear homogeneous differential equations of the second order.'

The summer meeting and colloquium of the Society will be held at Cornell University, Ithaca, N. Y., beginning August 19, 1901, and extending over a week.

EDWARD KASNER,
Assistant Secretary.

ZOOLOGICAL JOURNAL CLUB OF THE UNIVERSITY OF MICHIGAN.

AT the meeting of January 17th, Professor Jacob Reighard gave a paper on 'The Behavior of Plankton Nets.' This was based on plankton work done on Lake Erie in 1899 and 1900, in company with Professor H. B. Ward, under the auspices of the United States Fish Commission. The amount of water strained by the nets was directly measured by the use of a meter. It was thus possible to determine accurately the coefficient of the nets under various conditions, to judge as to their constancy, and to decide as to the correctness of the coefficients calculated by other investigators. The results have a fundamental bearing on the worth of all plankton work hitherto done; details will be published in a paper now under preparation.

January 24th, Mr. Raymond Pearl gave an account of work on the 'Electrotaxis of Infusoria.' The paper was accompanied by demonstrations with the projection apparatus. The following demonstrations were given:

1. The reactions of Paramecium to the current. The orientation and movement toward the kathode in a weak current were first shown. Then by a gradual increase in the intensity of the current the speed of swimming was made to decrease, and in a very strong current the characteristic changes in body form were seen to occur.

2. The reactions of a species of *Oxytricha*, one of the *Hypotricha*. It was seen that on making the current a part of the animals immediately oriented and went toward the kathode, while others swam in an oblique direction more or less transverse to the current. Attention was called to the fact that during the transverse swimming the animal often jerked sharply to one side, the direction of this jerk always being the same—that is, toward the right side of the organism. It was shown that by this process of frequently jerking toward the right side while swimming obliquely, orientation with the anterior end toward the kathode was ultimately brought about. It was pointed out that the reason why a part of the animals oriented at once, while others did so only in the indirect way thus described, was owing to the different position of the axes of the body with reference to the anode and kathode at the time of making the current. When the long axis of the body was transverse to the direction of the current and the oral side was toward the kathode, the transverse or oblique swimming

occurred, while from all other positions immediate and direct orientation with anterior end toward the kathode followed the closing of the circuit. On reversing the current, it was seen that the animals always gained the new orientation with anterior end to the new kathode by turning to the *right*. The fact was shown that sudden breaking (as well as reversal) of the current always caused the typical motor reflex that is given by the organism as a response to stimuli of other sorts—the animal always turning to its right.

3. The kataphoric effect of currents of moderate intensity in carrying *Chilomonas* and suspended particles in the water toward the anode was shown.

Following the demonstrations an account was given of the electrotactic reaction of a number of infusoria, and the bearing of the results on the recent work of other investigators was discussed. Reference was made to the reactions of some of the lower Metazoa which resemble in many ways the reactions of the infusoria.

H. S. JENNINGS,
Secretary.

DISCUSSION AND CORRESPONDENCE.

CORRECTION TO ANDRÉ'S ASTRONOMIE STELLAIRE.

THE favorable notice of André's 'Traité d'astronomie stellaire' contained in the number of SCIENCE for April 19, 1901, leads me to call attention to the following curious error contained in that work, which appears to have escaped the notice of all its reviewers.

In Vol. I., § 225, the author seeks to account for the well-known fact of a progressive variation in the periodic time—interval from minimum to minimum—of certain variable stars, and resorting to the hypothesis of a uniform motion in the line of sight, he proceeds by elementary mathematical methods to derive the effect of this motion in altering the periodic time of the light variations. It is almost self-evident that the effect of this motion is to produce a small but constant difference between the true period, and that furnished by observation, and this result is confirmed by the author's analysis when properly executed. But at the equation marked (2) in the text, André commits the algebraic error of dividing two terms of his equation by a certain factor, $n' - n$, while neglecting to divide the third term and obtains thereby an erroneous result which he interprets, correctly enough so far as the equation itself is concerned, as showing that the star's radial velocity produces a progressive change in the periodic time of its light variations. He applies this equation to certain well-known variables having secular terms in their light equations, and derives from purely photometric data, numerical values for their motion in the line of sight, which, although plausible enough in respect of magnitude, are entirely wrong in principle. The entire section entitled 'Terme séculaire' should be suppressed since it is completely vitiated by the algebraic error noted above.

GEORGE C. COMSTOCK.

AN APPEAL FOR COOPERATION IN MAGNETIC AND ALLIED OBSERVATIONS DURING THE TOTAL SOLAR ECLIPSE, MAY 17–18, 1901.

To further test the results obtained by the United States Coast and Geodetic Survey during the total solar eclipse of May 28, 1900, arrangements are being made for obtaining simultaneous observations of the magnetic elements and of allied phenomena over the entire globe during the next total solar eclipse, May 17–18, 1901.*

* CIRCUMSTANCES OF THE ECLIPSE.

	Greenwich Mean Time.				Longitude from Gr.		Latitude.	
Eclipse begins	May 17 d.	14 h.	59 m.	.9	51°	34′.4 E.	20°	21′.9 S.
Central eclipse begins	17	15	57	.6	40	11 .2 E.	27	27 .6 S.
Central eclipse at noon	17	17	28	.8	96	51 .9 E.	2	07 .1 S.
Central eclipse ends	17	19	10	.2	156	53 .6 E.	12	49 .0 S.
Eclipse ends	17	20	07	.9	145	04 .5 E.	5	38 .0 S.

To make the investigation exhaustive, an earnest appeal is herewith made to all persons who have instruments at their disposal to participate in the proposed observations and to put themselves in communication with the Division of Terrestrial Magnetism, U. S. Coast and Geodetic Survey, Washington, D. C., so that the necessary directions may be given them.

The scheme of work proposed embraces the following:

1. Simultaneous magnetic observations of any or all of the elements, according to instruments at the observer's disposal, every minute from May 17, 14 h. to 21 h., Greenwich mean astronomical time.*

[To insure the highest degree of accuracy attainable, the observer should begin work early enough to have everything in complete readiness in proper time.†]

2. At magnetic observatories all necessary precautions should be taken, so that the self-recording instruments will be in good operation, not only during the proposed interval, but also for some time before and after, and eye-readings should be taken in addition, wherever circumstances will permit.

3. Such meteorological observations as are possible for the observer should be made at convenient periods (as short as possible) throughout the interval. It is suggested that temperatures, *e. g.*, be read every fifth minute (directly after the magnetic reading for that minute).

4. Observations of atmospheric electricity and of earth currents should be made wherever possible, and any other phenomena of importance should be fully noted.

The request is made that observers send, as soon as possible, a full report of their work to the Superintendent of the Coast and Geodetic Survey.

L. A. BAUER.

*For America this interval occurs during the night hours of May 17th and 18th, civil dates, while for Europe, Asia, Africa and Australia, it occurs during the morning or afternoon hours (according to longitude of station) on May 18th, civil date.

† See directions followed by the Coast and Geodetic Survey during the recent eclipse, Journal 'Terrestrial Magnetism,' Vol. V., p. 143.

CLAYTON'S ECLIPSE CYCLONE AND THE DIURNAL CYCLONES.

IN a letter with the above title, in SCIENCE of April 12th (N. S., Vol. XIII., p. 589), Professor Bigelow criticizes my papers on the 'Eclipse Cyclone and the Diurnal Cyclones.' His criticism is subdivided into two heads: (1) concerning 'some minor errors' which he thinks he finds in the formulas, and (2) concerning the theory of the cold-center cyclone.

My method of treating the winds observed during the eclipse was first to find the mean wind during the eclipse at each station, then to find the deflections of the observed wind from this mean at intervals during the eclipse, in order to see if there were any systematic changes which might reasonably be attributed to the eclipse. In getting the mean wind, I plotted the individual observations of direction and velocity, taking them as nearly as possible at regular intervals, and drew the resultant direction for each station. As a check on this method and for greater exactness I next computed the mean wind for stations where the wind directions were recorded to degrees of azimuth, or the observations were otherwise considered sufficiently accurate. Observations to only eight points of the compass are not in general sufficiently accurate to show the eclipse wind. The general winds were from the southwest near the central path of the eclipse of May 28, 1900, in our Southern States, and the observations with which I had to deal were something like the following:

	Direction in degrees.	Velocity in miles.
(1)	S. 23° W.	3
(2)	S. 56° W.	2
(3)	S. 80° W.	1

These were plotted as shown in diagram 1 *A*, in which the continuous arrows are the observed winds and the broken arrow is the mean wind. With the above values the plotted mean was found to be S. 44° W. Calling the observed wind o and its velocity v, the mean was then computed as follows:

	sin. o	cos. o	(sin. o)v	(cos. o)v
(1)	.391	.921	1.173	2.763
(2)	.829	.559	1.658	1.118
(3)	.985	.174	.985	.174
Sum.			3.816	4.055

$$\begin{aligned}\log.\ 3.816 &= 0.582\\ \log.\ 4.055 &= 0.608\\ \hline \text{diff.} = \log.\ \tan.\ \theta &= 9.974\\ \theta &= 43°\end{aligned}$$

θ is the mean wind, and in computing it in the present case it was not necessary to consider the sign of the quadrant, as all were in the same quadrant. It is seen that the plotted mean and the computed mean agree within one degree, and agreements approximating to this I found throughout the work. Diagram 1 *B*, gives an example of another set of winds. These examples are only to illustrate the methods. In the actual computations there were from 10 to 30 observations. In my statement of the formula, Professor Bigelow thinks the v should precede the sin. o and cos. o, but why he attaches importance to this I do not know. The product of xy is the same as that of yx. It is distinctly stated in my paper that o is the observed direction and v the observed velocity, so I fail to see how there could be any misunderstanding; but, if a change is needed, it would seem to me best to give the formula thus:

$$\tan.\ \theta = \frac{\Sigma\ (v \sin.\ o)}{\Sigma\ (v \cos.\ o)}.$$

Having found the mean wind, my next step was to find the direction and velocity of the wind which, acting on the mean wind, would produce the observed wind in each case. This I sought to do by means of the well-known parallelogram of forces, as shown in Fig. 2. In this diagram, if *AB* represents the mean wind and *AC* the wind observed at some given time, then *AC* may be assumed to be deflected from the mean by a wind having the velocity and direction of *AD*. By plotting the observations in this way, I obtained the resultant winds for different portions of the eclipse area, and having plotted them, found evidence of a systematic circulation around the center of the eclipse area. This circulation followed the eclipse, and hence I conclude that it is caused by the eclipse. As before, I endeavored to check the plotted results and obtain greater accuracy by computing the resultant wind *AD* for certain of the stations. To do this, without changing the position of *AD*, I drew a line as represented by the dotted line *BD*, and from

FIG. 1.

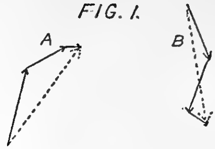

FIG. 2.

FIG. 3.

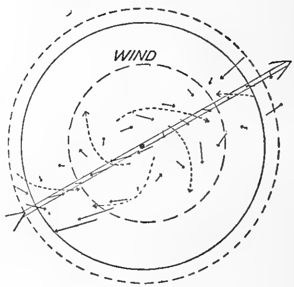

FIG. 4.

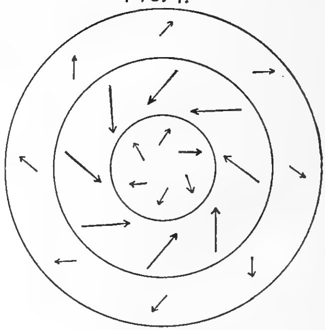

the triangle ABD proceeded to compute AD by well-known trigonometrical relations. I do not know why Professor Bigelow should find confusion because, in changing from plotting AD to computing AD, I changed the diagonal from AC to BD. I explained much of this in my paper, but, as I was writing for scientific men, it did not seem to me necessary to explain all the elementary processes.

Further details are given in the *Bulletin* of the Blue Hill Meteorological Observatory containing my discussion (*Annals* of the Astronomical Observatory of Harvard College, Vol. XLIII., Part 1, Observations and Investigations of the Blue Hill Meteorological Observatory, A. Lawrence Rotch, Director).

The final results as regards the wind circulation are illustrated in Fig. 3. In this diagram the arrows indicate, in the usual way, the direction of the resultant wind for different portions of the eclipse area, and the lengths of the arrows indicate the velocity of the wind. The central dark spot shows the area where the eclipse was total and the outer continuous circle shows the outer limit of the penumbra. The inner circle of broken lines shows the position of a probable ring of low pressure and the outer circle of broken lines shows the probable position of a ring of high pressure. The change of pressure found during the eclipse was in perfect accord with this latter conclusion derived from the wind circulation, and Professor Bigelow says that the observations of the Weather Bureau confirm my curve of pressure. The tendency to an anticyclonic circulation of the wind near the central area of the eclipse is confirmed by the observations of Professor Upton and Mr. Rotch in previous eclipses. (See *Amer. Meteor. Jour.*, Vol. IV., p. 456, Feb., 1888; also *Annals* of the Astronomical Observatory of Harvard College, Vol. XXIX., p. 18, 1893.)

I infer that Professor Bigelow does not seriously question the results as given by me, as he says Ferrel's 'cold-center cyclonic circulation * * * is just the opposite of the result of the eclipse observations.' It is the interpretation of the observations to which Professor Bigelow objects.

When I discover a new fact, it seems to me proper and even necessary for the advancement of science to consider the relation of the new fact to earlier known facts and to accepted theories and generalizations. In doing this I attempt to compare all the various facts and theories accessible to me and accept the best.

In considering the bearings of the eclipse data, I read among other things the views of Professor Bigelow in the International Cloud Report to which he refers. I find myself unable to accept his views of the air circulation in cyclones which he derives from the cloud observations, nor is his explanation of the diurnal change in pressure as an electromagnetic phenomenon satisfactory. However, in publishing results it is usually not possible for an author to enter into detail in regard to conclusions with which he is not in accord, nor is it best because it arouses strife and feeling. It seems best to give one's own conclusions and leave the future student to decide between conflicting views, as we have done.

In comparing my eclipse data with the different theories, I found that the results agreed so perfectly with certain views expressed by Ferrel concerning the cyclone with a cold center, that it leaves me no room for a new theory nor an improvement on his.

Ferrel says, "The conditions of a cyclone with a cold center which are the most nearly perfect are those furnished by each hemisphere of the globe, as divided by the equator, in which the pole is the cold center, and the temperature gradient from the pole toward the equator is somewhat symmetrical in all directions from the center. * * * The center of a cyclone with a cold center may, or may not, have a minimum pressure, according to circumstances. A certain amount of temperature gradient, and of pressure gradient which is independent of the gyratory motion, as explained in § 72 in the case of the general circulation of the atmosphere, is necessary to overcome the friction in the lower strata and to keep up the vertical circulation, upon which the cyclone depends; and the pressure gradient, which depends upon the temperature gradient and is independent of the gyrations, may be such that the increase of pressure in the central part due to this cause may be greater than the decrease of pressur

arising from the cyclonic gyrations, especially where surface friction is great" ('A Popular Treatise on the Winds,' pp. 338–339). This is from Ferrel's latest book, and note that he says the increased pressure 'is independent of the gyrations.' He explains that the velocity, v, of the air circulation tends to decrease the pressure at the center of the cyclone and not at the same time cause a rise of pressure, as is assumed by Professor Bigelow. The § 72 referred to reads as follows:

"The first effect of the motion in the upper strata of the atmosphere from the equator toward the pole, as in the case of the water flowing from the warmer toward the colder end of the canal, would be to fill up a little, as it were, the polar region with air from the equatorial, the effect of which is to increase the pressure a little in the former and to decrease it a little in the latter region, thus creating at the earth's surface and in the lower strata a gradient of pressure decreasing from the pole toward the equator, which would cause a counter current in the lower strata."

Ferrel does not state here whether the counter current would be anticyclonic or not, but states in other passages that such a gradient under the influence of the earth's rotation *would* produce an anticyclonic circulation. However, we are not left to inference in regard to Ferrel's views in this matter, for in the *American Journal of Science* (2 Ser., XXXI., p. 33, par. 15) he states his views explicitly as follows:

"Near the poles the tendency to flow toward the equator seems to be the greater, and causes a current there *from* the poles, which being deflected westward (5) causes a slight northeast wind in the north frigid zone, and a southeast wind in the south frigid zone. But this is only near the earth's surface, and the general tendency of the atmosphere in the upper regions must be toward the east as will be seen."

In the paper just quoted Ferrel gives a diagram of the air circulation in the polar cold-air cyclones which shows the circulation about the north pole as given in Fig. 4, in which I have made the north pole the center of the circulation for comparison with the eclipse circulation. The circulation around the pole indicated by Ferrel agrees with that shown by observations, as will be seen by comparing it with the carefully prepared charts in the 'Report on the Scientific Results of the Exploring Voyage of H. M. S. *Challenger*, 1873–76' (Vol. II.).

The similarity to the wind circulation found in the eclipse area must be apparent to every one (compare Figs. 3 and 4). The chief difference is that the anticyclonic circulation around the center, as compared with the surface inflow, is relatively larger in the eclipse circulation, and the outer circle of outblowing winds in the latter is only faintly indicated, owing to lack of observations. But the larger anticyclonic circulation around the center in the eclipse is exactly what theory would indicate for a circulation over a continental area where surface friction is great, and in a case where the gradient necessary to overcome the friction is feeble.

It may be asked why the diagram quoted here from Ferrel differs so radically from those given by Professor Bigelow. The explanation, I think, is simple. Ferrel, for the purpose of mathematical treatment, in the examples which Professor Bigelow quotes, was dealing with ideal cases in which there was little or no friction When his theory was applied to actual conditions on a globe possessing friction, his illustration of the cyclone with a cold center was like that I have given, with an increase of pressure and an anticyclonic circulation in the center at the earth's surface. The greater the friction the larger the central anticyclone must be to overcome the friction and maintain the circulation.

This view of Ferrel's theory is exactly that taken by Professor Davis, who is probably the ablest student of Ferrel in this country (*Quar. Jour. of the Roy. Meteor. Soc.*, April, 1899, p. 165).

The necessity of making every detail clear about the eclipse cyclone makes it necessary to omit consideration of the diurnal cyclones, but I think enough has been said to make clear the reasons for the contrasted views of myself and Professor Bigelow.

H. Helm Clayton.

Blue Hill Observatory,
April 16, 1901.

LELAND STANFORD JUNIOR UNIVERSITY:

To the Friends of Stanford University:

The undersigned, members of the University Council [professors and associate professors] of the Leland Stanford Junior University, in view of the numerous publications following upon the resignation of Professor Ross, which reflect on the University and its founder, and on our connection with it, deem it wise to issue the following statement.

In doing this we do not impeach the good faith of those who have interested themselves in this matter because of the question of university policy involved, but we wish to affirm our confidence in the University, its founder and its president.

We have examined all records, letters and copies of letters in the possession of the University bearing upon this case, and are agreed:

1. That in the dismissal of Professor Ross, no question of academic freedom was involved.

2. That in the dismissal of Professor Ross, President Jordan was justified.

CURRENT NOTES ON PHYSIOGRAPHY.

TOPOGRAPHIC ATLAS OF THE UNITED STATES.

THE second folio of this atlas, prepared like the first by Gannett, includes some striking topographic types. The Dismal swamp (Norfolk sheet, Va.) is given as an example of a coast swamp; discharge of its waters is prevented by the abundant vegetation on the flat uplands of a low coastal plain whose surface has been somewhat dissected and whose shore line has been extended inland by a slight submergence which has drowned many valleys. A number of the branching bays are headed by valley swamps of a different type from those of the plain. The lower Missouri is given as an

example of graded river (Marshall sheet, Mo.); that is, "its course has been eroded to almost as low a stage as possible, and its slope has become very slight, so that its cutting power is trifling." Reference to the balanced relation of load and carrying power might have here been made to advantage. There is perhaps some objection to citing the Missouri as an example of a normally graded river, as it is probable that the present Missouri has established its flood plain by aggrading rather than by degrading the valley floor. The Platte river (Lexington sheet, Neb.) is instanced as an 'overloaded' stream, of which class it is certainly a very striking example; but it is to be regretted that, as the term 'graded' was adopted for the Missouri, 'aggraded' or 'aggrading' was not employed for the Platte.

The linear Appalachian ridges are beautifully shown where the Susquehanna cuts across them (Harrisburg sheet, Pa.), types of their class for the world. The text of this example is somewhat less satisfactory than that of the others: tributaries are said to cut down their beds more rapidly than the main river; the sinuosities of the side streams are ascribed to the retarded erosion of the Susquehanna across the hard rocks, instead of to the pause in uplift, during which the inter-ridge lowlands were etched out; indeed, no explicit mention is made of these lowlands as local weak-rock peneplains, although the extraordinary enclosed meanders of Conedoguinet creek are referred to a time when the Susquehanna was 'held at one level for a considerable period'; 'subsequently, by some means, the river succeeded in lowering its bed' and its tributary followed suit. 'By some means' might be well replaced by 'after an uplift.' The diagram giving a section of some of the ridges does not properly represent the dip of their strata, and the Medina formation is labelled Potsdam. Finer examples than the alluvial fans ('cones') of southern California and the huge basin of Crater lake in Oregon could not be selected for the closing numbers of this folio, which contains ten sheets in all.

TERRACES FRONTING THE ROCKY MOUNTAINS.

AT various points piedmont to the Front range of the Rocky mountains in Colorado, there are sloping gravel-covered plains or mesas, into which the streams have cut their valleys. Lee describes some of these (The origin of débris-covered mesas of Boulder, Colorado. *Journ. Geol.*, VIII, 1900, 504–511, 4 figs.) and emphasizes the contemporary date of the graded piedmont surface, beveled across the underlying rocks, and the deposits of coarse waste with which it is covered; both are the product of the lateral shifting of streams, cutting on one side and filling on the other; the waste, 25 to 50 feet in thickness, being chiefly a flood deposit. The present action of the stream at Boulder in its channel and on its flood plain imitates the former action by which the intermediate mesa terrace and the higher mesa were produced. It is suggested that the three grade plains thus indicated "do not seem necessarily to require the assumption of any change in the attitude of the land subsequent to the elevation of the mountains, but are the natural sequences of erosion as influenced by the local distribution and difference in hardness of the formations involved." A gradual down-cutting with an active lateral shifting appears to account for the features described.

THE FORMATION OF DESERTS.

'DAS Gesetz der Wüstenbildung in Gegenwart und Vorzeit' (Berlin, 1900, 175 p., 50 views) is a new work by Walther, already known for his studies of desert denudation. The book opens with a comparison of sea floors and desert surfaces; each one becomes smoother by filling with waste from the enclosing highlands, the coarser waste remaining near the margins; but the deposits in one contain few records of life, while those of the other may teem with fossils. Special accounts are given of the process and results of dry weathering, of wind erosion (deflation) and of water action in arid regions. The forms assumed under these processes are well described and illustrated. Rock ledges are left bare, frequently with a pitted surface; they are sometimes found worn down to a small relief and strewn with a scanty covering of waste. The popular impression that deserts are plains is held to be not so far from the truth as is sometimes taught, since so large a part of arid landscapes is degraded

or aggraded to a nearly even surface. The crescentic sand-dune is taken as a normal form on an open surface. The necessity of a former pluvial period to explain the wadies of deserts, as stated by some writers, is doubted; and in spite of the violence of occasional cloud-burst floods, the chief agency in the preparation of desert topography is held to be the wind; a conclusion that seems to have been long familiar to the Bedouin, just as the transportation of erratics by a former extension of glaciers has long been known to Swiss peasants. The importance of identifying ancient desert formations in the geological series is emphasized.

Although peneplanation under arid conditions is not excluded from the Walther discussion, the systematic advance of the processes of arid denudation through an ideal cycle and the description of the forms thus successively developed are not fully presented. Old and young deserts are not clearly separated. In some arid regions, the marginal deposits of the coarse waste rise upon the flanks of the enclosing mountains; in others a piedmont slope of evenly degraded rock, veneered with thin sheets of waste, slopes gently forward from the mountain base. The first is probably a younger form than the second; but no one has yet studied out the full series of still younger and still older forms of an arid landscape.

W. M. DAVIS.

THE AMERICAN GEOGRAPHICAL SOCIETY.

THE American Geographical Society will move into its new building in 81st Street, New York, in the course of the next two or three months. The Society has at present about 1,200 members and, to still further increase its numbers, has sent out a circular, from which we quote the following:

The objects of the American Geographical Society are: The collection, discussion and diffusion of geographical information; the promotion of the exploration of our territory and of the survey and preservation of our harbors; the establishment in the chief maritime city of the Union of a place where will be afforded the means of obtaining accurate information of every part of the globe, and the registration and careful record of discoveries and studies in geography and the related sciences.

The Society was founded in 1852. One of but twelve similar societies at that time, it now exchanges its publications with three hundred scientific associations scattered throughout the world.

The Society has outgrown the house, No. 11 West Twenty-ninth Street, in which it has been lodged for more than twenty years. A handsome fireproof building is now being erected in West Eighty-first Street, opposite Manhattan Square. This will afford perfect security to the library of 30,000 volumes—one of the foremost geographical libraries of the world—the thousands of maps and charts and the collection of atlases of the sixteenth, seventeenth and eighteenth centuries, now in the map rooms, and will also provide ample accommodation for readers and students.

Travelers, men of science, and others properly accredited, are welcomed at the rooms of the Society and freely offered the use of the library and collections.

The Society is now free from debt and possesses a property which has of late been steadily growing in value.

It is desired to add to the number of fellows on the roll in order to strengthen and extend the influence and the usefulness of the Society.

No special qualification for fellowship is required other than interest in the spread of knowledge and the advancement of science. The annual dues are $10.

RESOLUTION OF THE COMMITTEE OF CENTRAL NATURALISTS.

AT a meeting of the committee appointed by the Chicago meeting of naturalists to arrange for the next meeting, held at Chicago, March 28th, the following was voted. The vote has since been submitted to a number of the older members of the American Society of Naturalists living in the Central States and has been approved by them. It may, therefore, be taken to represent the prevailing sense of the naturalists of the Central States.

VOTED: Whereas, the naturalists of the Central States propose to meet annually at some convenient point for intercourse and the reading of papers;

And whereas, no point east of the Alleghenies (to which territory the meetings of the American Society of Naturalists are by its constitution confined) is practicable as such meeting point;

And whereas, the central naturalists would view with approval the formation of a national body which might properly be called the Amer-

ican Society of Naturalists, by which name the eastern society is now known;

And whereas, it is desirable that the organization of the central naturalists should be coordinate with the eastern society;

And whereas, it is desirable that all the naturalists of the country should, as far as possible, come together from time to time in a national general gathering;

Resolved, that the naturalists of the Central States form a permanent organization and that they favor a coordinate relation of this association and that of the Eastern States, as eastern and central branches respectively of the American Society of Naturalists.

That the two organizations meet annually in their respective territories (except as stated below), have the same conditions of membership, elect their own officers and collect and disburse their own funds;

That the records of the two branches, including lists of members, be published jointly at joint expense and under the joint editorship of the secretaries of the two branches;

That every third year the two branches meet together alternately in the East and in the Central States, that the officers of the meeting be those of the receiving branch, and that visiting members enjoy full privileges, except as may be agreed upon at the time of joint ratification of this resolution;

That this resolution be transmitted to the American Society of Naturalists at its Chicago meeting, with the suggestion that it be referred to a committee to arrange further details and that the report of the committee be received and acted upon at the same meeting;

That, a copy of these resolutions be printed in SCIENCE to give an opportunity for full discussion of them.

C. B. DAVENPORT,
Secretary of Committee.

SCIENTIFIC POSITIONS UNDER THE GOVERNMENT.

A NUMBER of important scientific positions will be filled by civil service examination on June 3d. It is desired to establish an eligible register for the positions of plant physiologist and plant pathologist in the office of Plant Industry, United States Department of Agriculture, with salaries of $1,800 per annum. The competitors will not be assembled for this examination, but must make application for the special form and send the following information not later than the date mentioned. The statements in physiology, those in pathology being similar, together with the weights, are as follows:

1. A statement of the line of study pursued in the colleges in which the competitor has received degrees or in which he has carried on work:
   (*a*) Technical and practical work with plant physiology. 20
   (*b*) Scientific research in physiology and coordinate lines 20
   (*c*) Submission of a list of articles on physiology and related subjects published by competitor 25
2. A statement of the competitor's experience as an executive officer or teacher..................... 15
3. A statement of not less that 500 words setting forth the present status and prospective development of plant physiological research........ 20

An examination will be held on the same day in any city where postal free delivery has been established for the position of assistant in the seed laboratory of the Division of Botany with a salary of $1,200, the subjects and weights being as follows:

1. Essay on methods of conducting purity tests (orthography and penmanship will be marked on this exercise) 10
2. Structural botany............................ 15
3. Morphology of the seed 20
4. Reading botanical German 10
5. Drawing of seeds 15
6. Identification of seeds............................... 30

An examination under similar conditions will be held for the position of a field assistant in the Department of Agriculture, with a salary of $1,000. Here the subjects and weights are:

1. Forestry......................... ...(sheet 1).......... 60
2. Botany...............................(sheet 2).......... 10
3. English composition.............(sheet 3).......... 10
4. Education and experience......(sheet 4).......... 20

An examination for the position of computer in the Division of Forestry, with a salary of $1,000, will also be held, the subjects being:

1. Forest mensuration................ 60
2. General forestry.. 25

3. Education and experience............................ 15

For the position of ethnologist in the Bureau of American Ethnology, at a salary of $1,500, an examination will be held as follows:

1. Essay on ethnologic and archeologic subject..... 20
2. Experience in ethnologic work (*a*) in the field; (*b*) in writing, teaching, etc 20
3. Original publications on ethnologic and archeologic subjects.. 20
4. The geographic, ethnologic, and archeologic features of Arizona and New Mexico........... 30
5. Literature of ethnology and archeology of southwestern United States........................ 10

SCIENTIFIC NOTES AND NEWS.

A MEETING was held at Cambridge University on April 27th to arrange for some acknowledgment of the services to science and the University of Professor G. D. Liveing. Professor Liveing is now seventy-three years of age. In 1852 he organized the chemical laboratory at Cambridge which was the first scientific laboratory in the University.

DR. EDMUND B. WILSON, professor of zoology at Columbia University, and Dr. J. Playfair McMurrich, professor of anatomy at the University of Michigan, are among the Americans who will attend the International Zoological Congress to be held in Berlin from the 12th to 19th of August.

THE U. S. Biological Survey has been engaged for several years in studying the geographic distribution of animals and plants in Texas, with a view to the preparation of maps showing the limitations of the life zones and faunal areas in that State. Mr. Vernon Bailey, chief field naturalist of the Biological Survey, has charge of this work and has recently gone to southwestern Texas to begin field operations for the season of 1901. He is assisted by Mr. H. C. Oberholzer.

DR. D. A. CARMICHAEL, recently appointed federal quarantine officer in San Francisco, has arrived in that city. He has presumably been given this appointment on account of his success in suppressing the plague in Honolulu.

DR. GEORGE BLUMER, of the Bender Laboratory at Albany, has been appointed director of the Bureau of Bacteriology and Pathology, newly established by New York State.

PROFESSOR H. POTONIÉ and Dr. Aug. Denckmann have been appointed geologists in the Geological Bureau at Berlin.

MR. EVELYN BALDWIN, who is shortly to lead the North Polar expedition equipped by Mr. Ziegler, has gone to Norway and Denmark in connection with his preparations. He will shortly go to Dundee to join the steamer *America* which he recently acquired for the expedition.

MR. W. H. C. PYNCHON has given a course of six lectures at Trinity College upon the 'Geology of the Connecticut Valley Lowland.'

MISS C. M. DERICK, lecturer in botany at McGill University, has been granted a year's leave of absence, and will study botany under Strasburger at Bonn.

DR. THOMAS CONRAD PORTER, since 1866 professor at Lafayette College, died on April 27th, at the age of seventy-nine years. Dr. Porter at first taught the natural sciences at Lafayette College, while later his work was confined more especially to botany. He was made emeritus professor four years ago, but remained dean of the Pardee Scientific School. He was the author of a 'Botany of Pennsylvania,' 'A Synopsis of the Flora of Colorado' and other works. He was a man of great learning, belonging to the older school of naturalists, and, although he left very valuable collections and notes, it is to be feared that a vast fund of valuable information is lost by his death.

THE death is announced, at the age of 82 years, of Mr. James Douglas Reid, who was interested in the construction of the early telegraph lines in this country. He was the author of a book entitled 'The Telegraph in America,' and for a while conducted a journal devoted to telegraphy.

WE regret also to record the death at the age of 82 years, of F. K. M. Feofilaktow, lately professor of geology in the University at Kiew, of Dr. Adolph Hirsch, professor of astronomy in the University of Neuchatel and director of the observatory, and of Dr. S. Lamanski, the physicist of St. Petersburg.

THE International Association of Academies

will hold its next meeting in London in 1904. It does not seem possible to obtain information in regard to the recent meeting until the *Comptes rendus* are published.

THE Thirty-ninth Congress of the Sociétés Savantes met at Nancy last month with about two hundred and fifty delegates in attendance.

A CONFERENCE of State University presidents will be held at the University of Illinois on May 1st and 2d. The following presidents are expected to attend the meeting: James H. Baker, of the University of Colorado; Joseph Swain, of the University of Indiana; George E. McLean, of the University of Iowa; Acting Chancellor W. C. Spangler, of the University of Kansas; James B. Angell, of the University of Michigan; Cyrus Northrop, of the University of Minnesota; R. H. Jesse, of the University of Missouri; Chancellor E. B. Andrews, of the University of Nebraska; W. C. Thompson, of the University of Ohio; W. E. Stone, of Purdue University, and Acting President E. S. Birge, of the University of Wisconsin.

A METRIC Association is being organized in Canada, the object of which is to prepare the people for the adoption of the metric system.

THE French Association of Anatomists held its third meeting at Lyons in April under the presidency of M. Renaut. There were about fifty students of anatomy in attendance, including a number of foreigners. The next meeting of the Association will be held at Montpellier in 1902 under the presidency of M. Sabatier.

THE committee of the British National Physical Laboratory announces that it is prepared to receive applications for appointments as members of the staff of this laboratory, the buildings of which will be in the grounds of Busheyhouse, Teddington. It will appoint a superintendent of the engineering department, with a salary of £400 per annum; one or two assistants in the physics department, with salaries of from £200 to £250 per annum; and one assistant in the physics department to take charge of such chemical investigations as may be required, with a salary of £200 per annum. The committee is also prepared to receive applications for a small number of junior assistantships, at salaries of from £100 to £150 per annum. Applications, accompanied by a limited number of testimonials, should be made, not later than May 24th, to the director, National Physical Laboratory, Old Deer Park, Richmond, Surrey.

PREPARATIONS are being made by the Division of Forestry of the Department of Agriculture to remove from its present crowded quarters to offices on the sixth, seventh and eighth floors of the Atlantic building. Under the reorganization plan of the Department of Agriculture, authorized by the last Congress, the Forestry Division will, on July 1st, become a bureau of the Department.

THE American Museum of Natural History, New York, has acquired a valuable collection of Peruvian antiquities, including Indian pottery, musical instruments, stone implements, gold and silver vessels, and the like.

THE New York Academy of Medicine has been given a fund of $10,000 by Mrs. S. B. Gibbs and Miss G. B. Gibbs for the establishment of the Edward N. Gibbs memorial prize fund.

M. SANTOS-DUMONT, to whom the prize of the Paris Aeronautical Club was awarded in 1900, has returned the money to the Club to be used as the foundation for a new prize. The amount is 100,000 fr., and the income is to be given to the members of the Club who can make a circuit of the Eiffel Tower and return to the point of departure at St. Cloud.

A TELEGRAM has been received at the Harvard College Observatory, dated May 2d, from its station at Arequipa, stating that a very bright comet was seen at eleven hours thirty-five minutes (Greenwich mean time) in R. A. $3^h\ 30^m$ and Dec.—1°. This is presumably the comet announced by Dr. Gill, April 24, 1901. It seems to be no longer visible in the northern hemisphere.

THE *Electrical World* states that the Administration of Posts and Telegraphs contemplates the introduction of wireless telegraphy in Spain on a large scale. It is rumored that Marconi will soon go to Madrid to arrange matters with the Government. The Balearic and Canary Islands are first to be connected by this system, which will then be extended from these islands

to the Continent. Several places on the coast of Morocco, such as Ceuta, etc., will be connected with Algeciras and Tarifa.

MR. H. E. BIERLY, professor of biology in the State College at Tallahassee, Fla., succeeded during the last meeting of the State Teachers' Association in having child-study made a special department of the Association, and was elected director. During the last month the women's clubs, mothers' clubs and kindergarten associations in the State have been taking up the subject under his direction. The State superintendent of public instruction recommends the work officially. All the colleges, normal schools, etc., in the State are giving their hearty support to the movement and are very much interested in the subject.

THE Paris correspondent of the New York *Evening Post* writes as follows regarding an address made by Professor Bernheim, at the congress of French learned societies held recently at Nancy:

> The venerable Professor Bernheim, the founder of the famous school of Nancy, which still holds out against Charcot and the Salpêtrière, made an impassioned declaration of his beliefs and principles. He utterly denies the hypnotic character of the phenomena observed in the patients of the Salpêtrière, whom he declares to be mere hysterical personages. He developed at length his theory of the universal suggestibility of all men; he denied once more the existence of anvthing like a magnetic fluid, under whatever name. There is a radical defect in experiments concerning thought transferrence, which he says ought rather to be spoken of as treason than as a veritable transferrence of brain influence. There was some bravery in this renewed declaration of opinion on the part of one who has already suffered excommunication from the most recent science.

Just what is meant by the last sentence is not clear, but it is apparently intended to indicate that Professor Bernheim's science is antiquated because he does not believe in the vagaries of the Salpêtrière or in telepathy. It is difficult to understand why a journal as carefully edited as the New York *Evening Post* should not submit its scientific news to an expert for revision.

THE London *Times* states that an apparatus, invented by Mr. Poulsen, of Copenhagen, for recording telephonic messages is now being shown in London. The invention, which can be used in substitution for, or in cooperation with, any ordinary telephone receiver, consists essentially of a long steel wire or ribbon, which passes rather rapidly before the poles of a small electromagnet. This electromagnet, which is wound with very many turns of exceedingly fine wire, is inserted in the telephone circuit by the current in which it is magnetized. The steel wire is of course also magnetized, and the essence of the machine lies in the fact the magnetization induced in the successive portions of the wire varies in agreement with the undulations of the electric current in the telephone circuit, produced by the voice of the speaker. To read the message it is only necessary to pass the steel wire in the same direction past the poles of the same or a similar electromagnet, when the same undulations will be set up in the current passing through its coils and consequently the same sounds reproduced in the attached receiver. In the instruments in London these reproduced sounds are remarkably true and pure. It is said that the same message may be reproduced from what may be called the sensitized ribbon an indefinite number of times, but, if it is desired to remove the record, that can be simply effected by subjecting the wire to a constant magnetizing force, such as is obtained by passing an unvarying current through the electromagnet. In one form of the machine ordinary pianoforte wire is employed, and is wound helically round a brass cylinder rotated by a electric motor. In another, which is adapted for longer messages, thin steel ribbon is wound on and unwound from two rolls alternately. The curious thing here is that, although no magnetic screen or insulator is interposed between the successive layers of ribbon, the magnetization produced in every portion of them is preserved unaltered. In a third form, a continuous steel band is stretched between two revolving pulleys; at one point is placed the electromagnet connected with the transmitting telephone, and beside it is any number, limited only by considerations of space, of electromagnets connected with receiving telephones, each of which in turn receives the message impressed on the ribbon. After the ribbon has passed all these electromagnets it is sub-

jected to the influence of several permanent magnets by which it is, so to speak, wiped clean and prepared to receive another series of magnetic impressions.

M. DARBOUX, in welcoming the delegates to the International Association of Academies at the recent Paris meeting, according to the report in the London *Times*, attributed the original idea of association for scientific research to Lord Bacon, recalling the curious conception of the College of the Six Days' Work or the House of Solomon, which, however, was never realized. To-day, such was the range of scientific activity, no such scheme could ever be realized, and only the common agreement and reciprocal support of the nations could suffice even to undertake the solutions of the problems which were now imposed in all their multiplicity on the attention of the world. Such agreement had been secured for a certain number of special questions, such as the International Bureau of Weights and Measures, the International Geodetic Association, the Association for the Map of the Heavens and, notably, the international catalogue of scientific literature, due entirely to the initiative of the Royal Society. M. Darboux then continued: This international cooperation, which has always proved its value in all the cases where it has been found indispensable, will be assured in a lasting, normal and universal way by the formation of our Society. The task that we have undertaken may appear difficult, but it has become absolutely necessary, and the spirit actuating us ought to give us the assurance that we shall succeed by our united efforts in overcoming all difficulties. In constituting under a visible and permanent form this universal academy, which had been conceived and prepared by Leibnitz, many of whose other dreams, moreover, have been realized or are being realized, our Association will render to civilization and science a service of which it is impossible to exaggerate the importance. Thanks to it, the man of science devoting his life to the most delicate or the most abstract researches will cease to feel himself isolated, while still preserving that independence which is the greatest good and the primary need for the investigator. By uniting in the different academies all those who are studying the same subjects, by giving them, if they wish it, the opportunity of joining in a common work, by drawing the attention of the governments to all the schemes the speedy realization of which is necessary or desirable, by indicating to them also the means of executing these schemes in the most favorable conditions and with the greatest possible saving, and by proposing and preparing, through the common understanding of *savants*, in the domain of theory the agreements of peoples on the basis of practice and facts, our Association is destined to become rapidly one of the most powerful instruments of concord and of progress. It is with this firm conviction that I declare open the first general assembly of the International Association of Learned Societies.

AT a meeting of the Geological Society of London, on March 6th, Professor George Frederick Wright, of Oberlin College, presented a communication entitled, 'Recent Geological Changes in Northern and Central Asia,' the paper being the outcome of a journey made by the author in company with Mr. Frederick B. Wright in 1900–1901. He said that in North America an area of about 4,000,000 square miles was brought under the direct influence of glacial ice during the Glacial Epoch. The result of six weeks spent in Japan was to show that there are no signs of general glaciation in Nippon or Yesso. Neither is there any sign of glaciation along the border of the Mongolian Plateau, where the general elevation is 5,000 feet, but the whole region is covered with lœss. This has usually accumulated like immense snow-drifts on the south-eastern or lee side of the mountains, and in it houses and villages are excavated. In the mountainous region, strata of gravel and pebbles are so frequent in the lœss, that it is necessary to invoke both wind and water in order to explain fully the origin of the deposit. At the present time the lœss in the interior is being washed away by streams much faster than it is being deposited by the wind. The journey across Manchuria from Port Arthur along the Lao-Ho and Sungari rivers was through valleys choked with alluvium, and there was no evidence that the drainage of the Amur had ever been reversed by ice, like that

of the St. Lawrence; nor was there any other evidence of glaciation. The lower course of the Amur indicates subsidence. Again, there are no signs of glaciation on the Vitim Plateau. Lake Baikal appears to be of recent origin; it is 4,500 feet deep and has not been filled by the great quantities of sediment brought down by the Selenga and other rivers. Although glaciers could frequently be seen on the mountains which border the Central Asiatic Plateau to the northwest, there was no evidence that the glaciers had ever deployed on the plain. The lœss-region of Turkestan, and indeed the whole area from the Sea of Aral to the Black Sea, appears to have been recently elevated, in some places as much as 3,000 feet. Desiccation took place at the same time, so that the larger lakes are only brackish or still fresh. Direct evidence of this in the form of deposits is given. The author thinks it likely that the absence of glaciation in northern Asia may have been due to the rainlessness of the region and that, while America was elevated, Asia was depressed during the Glacial Epoch.

THE Brussels Academy of Sciences announces, as we learn from *Nature*, the following prize subjects for 1901: New researches upon the compounds formed by the halogens between themselves (800 francs); the determination of the form of the principal terms introduced into the formulæ of nutation in obliquity and longitude by the elasticity of the earth's crust (800 francs); historical and critical discussion of Weber's experiments on unipolar induction, and new experiments bearing upon the laws and interpretation of this physical fact (300 francs); a contribution to the study of mixed forms with a number of series of variables, and the application of the results to the geometry of space (600 francs); history of researches on the variation of latitude, and a discussion of the interpretations of this phenomenon (600 francs); investigations of the physiological rôle of albuminoid substances in the nutrition of animals or plants (800 francs); new researches on the organization and development of *Phoronis*, and the relations existing between the animals *Rhadopleura* and *Cephalodiscus*, and the class to which the name Enteropneusta has been applied (1,000 francs); description of simple substances, sulphates and binary compounds of Belgian soil (800 francs); researches on the influence of external factors on karyokinesis and cellular divisions in plants (800 francs).

WE learn from the *Lancet* that on April 10th the committee of the Marine Biological Station at Millport received representatives from various educational bodies at the Station, with a view to extend a knowledge of the educational resources at their command. Dr. J. F. Gemmill, the president, gave a sketch of the new teaching arrangements, which include a course of lectures on marine zoology and botany, with practical demonstrations on Saturdays from April 27th to June 15th, inclusive, the introductory lecture to be delivered by Sir John Murray, K.C.B., F.R.S. The visitors were afterwards conducted over the laboratories, tank-room and museum by Dr. James Rankin, and then proceeded on a dredging excursion on the steam-launch *Mermaid*, recently presented to the institution. It is hoped that the new teaching arrangements will encourage the practical study of natural history among board school and other teachers, upwards of 40 of whom have already entered their names for the new classes. The science students in the University of Glasgow also find the station an admirable center for practical work, and the younger dons in the science faculty are energetically assisting in its development.

IT is announced that, through an expedition to Kenai Peninsula by Mr. Andrew J. Stone in the interests of the American Museum of Natural History, the Museum has received some fine specimens of the big Alaskan moose, recently described as *Alces gigas*. This animal is the largest known representative of the deer tribe, and differs from the moose of eastern Canada and Maine in its larger size and darker colors, but especially in the great development of its antlers, which are much larger than those of the eastern moose. Mr. Stone also obtained specimens of two species of bear and the head of a fine caribou. Other recent accessions of note are a collection of mammals from Peru, consisting of about one

hundred and fifty specimens, and representing some twenty-five species, of which quite a number proved new to science and others had been only recently described from specimens received at the British Museum. With this collection was also received a small collection of birds, which contained many species new to the Museum collection and several new to science.

UNIVERSITY AND EDUCATIONAL NEWS.

Mr. George W. Carroll, of Beaumont, Texas, has given $60,000 to Baylor University, at Waco, Texas, for a science building.

By the will of Miss Mary Shannon, of Newton, Mass., $125,000 is distributed among charitable and public institutions. Wellesley College receives $15,000 and several institutions for the education of negroes receive sums ranging from $5,000 to $10,000.

A building to contain the bacteriological and pathological laboratories is to be erected at the University of Michigan at a cost of $100,000.

As we have already announced the degree of Bachelor of Arts will hereafter be given at the University of Michigan without any requirement in the classical languages either at entrance or afterwards. It has now been decided that there will be no required subjects in the course, except English in the freshman year. In addition first-year students may select three subjects from the following: Greek, Latin, French, German, history, mathematics, physics, chemistry, biology.

It is expected that Cornell University will this June grant 380 baccalaureate degrees and 74 advanced degrees. They are apportioned as follows: 125 A.B. degrees; 1 B.S.; 44 LL.B.; 16 B.S.A.; 9 D.V.M.; 5 B.S.F.; 6 B.Arch.; 51 C.E.; 123 M.E. (including electrical, marine and railway M.E.); and 21 A.M. degrees; 9 M.S. in Agr.; 4 M.C.E.; 10 M.M.E.; 1 D.Sc.; 29 Ph.D.

The forty-five graduate students of the New York University, with one exception, have signed the following resolution, and forwarded it to the chancellor of the University and to the president of the University Council:

Resolved, that we, the undersigned members of the Graduate School of the New York University, sincerely regret the resignation of Professor Edward F. Buchner, Ph.D., Samuel Weir, Ph.D., and Professor Charles H. Judd, Ph.D., whose departure threatens the high standard and continuity of our courses, as well as the usefulness of the Graduate School, and respectfully request the authorities of the University to secure the continued services of those professors. Some of us also hold our Bachelor's and Master's degrees from this and other universities, and we believe that we are competent judges of professional worth, and hereby desire to express our unqualified repudiation of the aspersions cast upon the professional efficiency of Dr. Edward F. Buchner. Many of us have been in his classes, and we have uniformly found Dr. Buchner to possess a rich and rare gift of insight, a profound grasp of philosophical problems, as well as felicitous power of expression and painstaking and sympathetic class-room methods. Believing that this rare gift as a teacher and a scholar makes him an ornament to his profession and a credit to the University, we trust that the University Council will give this resolution full weight in their deliberations.

Professor E. A. Ross, of the University of Nebraska, recently of Leland Stanford Junior University, has been appointed a visiting lecturer at Harvard University for next year.

Owing to the recent complications, Dr. Arthur O. Lovejoy, associate professor of philosophy at Stanford University, has resigned.

Dr. Max Farrand, professor of history at Wesleyan University, has accepted the chair of history in Stanford University.

Dr. Edmund Arthur Engler, professor of mathematics at Washington University, St. Louis, and dean of the College of Engineering, has been elected president of the Worcester Polytechnic Institute.

Mr. J. W. H. Pollard, Dartmouth '95, has been appointed physical director in Lehigh University.

Dr. J. Stafford, lately of the University of Toronto, has been appointed lecturer in zoology at McGill University.

Dr. J. A. Gmeiner has been appointed associate professor of mathematics at the German University of Prague.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE PLAGUE IN SAN FRANCISCO.

IN the spring of 1900 the city bacteriologist of San Francisco and the quarantine surgeon of the Marine Hospital Service, stationed at Angel Island, San Francisco Bay, made the discovery that the death of a Chinaman had been caused by plague. In accordance with the provisions of the laws governing these two officers in their respective functions, the case was officially reported. Other cases soon developed, and the occurrence of these cases was likewise officially reported. The reports of the quarantine surgeon were published in the Public Heath Reports of the Marine Hospital Service in accordance with law and with international agreements. The truth of the reports was at once questioned by the larger portion of the local public press, the objections being partly of a political and partly of a commercial character. A certain portion of the medical profession also opposed the recognition of the diagnosis, and the opinions of these physicians constituted the basis of the denial by the press of the truth of the existence of plague. The diagnosis had been established in accordance with the conceptions of plague as determined by the scientific study of the

disease in the Orient by Yersin and Haffkine, and by the various plague commissions which were sent to the Orient by various European governments for the study of plague; in short, the diagnosis was established precisely as it was in India, China, Japan, Portugal, Alexandria, Sydney and Cape Town; and the fact that the scientific methods, which in the countries quoted are unreservedly accepted as trustworthy and reliable, were in San Francisco disregarded and ridiculed is a sad commentary upon that portion of the medical profession which maintained the negative attitude.

Fearing that the State Board of Health might quarantine the city and that other States might quarantine the city, or even the State, to the vast injury of public and commercial interests, the commercial interests of the city solicited the establishment by the City Board of Health of a quarantine of 'Chinatown,' the portion of the city occupied by the Chinese in which all the reported cases had occurred. This request was acceded to, and the quarantine was established. At the solicitation of the railway companies, the Marine Hospital Service, through its surgeon-general in Washington, though against the protest of the surgeon stationed at Angel Island, laid a similar quarantine against 'Chinatown.' The public was given to understand that plague was a disease of frightful contagiousness and rapid spread, and that this quarantine was necessary to prevent the spread of the disease through the entire city. The quarantine, though inadequately enforced and obviously ineffective, was quite naturally obnoxious to the Chinese residents of the quarantined area, and they sought relief in the courts.

In the opinion rendered upon the case, Judge Morrow decided the establishment and maintenance of the quarantine illegal, but marred what was, under the laws, a correct decision by the prejudicial and unwarranted statement that no cases of plague had existed in San Francisco. That the quarantine was, in the light of our knowledge of plague and in the light of the Oriental experiences with the disease, an unwarranted and mistaken procedure is obvious. As a rule plague is not a personal infection, it is a house infection; the best evidence of this fact is the statement of one of the European commissions that about the safest place in Bombay is the plague hospital. As a general rule plague may be said to become a personal infection only when the pneumonic form is prevalent, and even under such circumstances the sensitiveness of the *Bacillus pestis* to sunlight and desiccation renders the infectiousness of the disease much less than is observed with other infections. As stated, the public in San Francisco had been led to believe that plague was a disease of frightful contagiousness; when then the quarantine was raised, and the Chinese population was allowed to go where it chose in the light of the aforestated information, the disease was expected to spread at once through the city. It did, of course, nothing of the sort. And naturally the general public at once lost confidence in the local board of health and in the correctness of the diagnosis.

Following this date fresh cases occurred from time to time, and the occurrence of these cases was officially reported by the city bacteriologist and by the surgeon of the Quarantine Station of the Marine Hospital Service. The public press then began a campaign of personal abuse of Surgeon Kinyoun, the quarantine surgeon of the Marine Hospital Service, though this officer had done nothing but follow his orders and obey the law. Matters dragged on until the opening of the State Legislature. In his message, his Excellency Governor Gage denied the existence of plague in the State and passed severe strictures upon the surgeon of the Marine Hospital Service. A motion was then introduced into the Legislature requesting the National Government to recall surgeon Kinyoun, the implication again being that Dr. Kinyoun had exceeded his authority, a charge which was entirely unfounded, as every other surgeon in the service would of necessity have done exactly as did Dr. Kinyoun. Dr. Kinyoun thereupon demanded an investigation of the hygienic state of affairs in San Francisco. The Treasury Department thereupon sent to San Francisco a special committee composed of men of international reputation as experts in matters of the kind, men entirely without connection with the Marine Hospital Service, and in fact connected with large institutions of public learning. The committee consisted of Professor Flexner, of the University of Pennsylvania, Professor Novy, of the University of Michigan, and Professor Barker, of the University of Chicago.

Upon the advent in San Francisco of these gentlemen, bills were introduced into the State Legislature making it a criminal offense for any one to report the existence of plague without the confirmation of the State Board of Health, and prohibiting the handling of cultures of the *Bacillus pestis* as prejudicial to the public health; these bills were not pushed, and did not pass; they are mentioned simply to illustrate the mental attitude from which they sprang. It had been previously charged that the bacteriologists reporting the cases of plague had intentionally infected with the *Bacillus pestis* the bodies of Chinamen dead of other causes, in order to bolster up their diagnoses; this absurdly vindictive charge is repeated simply to illustrate to what an appalling extent of mental and moral error prejudice will carry men. The special commission spent several weeks in San Francisco, saw and studied six cases of plague, and presented a report confirming the existence of the disease in the city. On the receipt of the information of the contents of this report, a committee of citizens went to Washington, and an agreement was entered into with the national authorities, that the city of San Francisco and the State of California were to furnish the funds wherewith the section of the city known as Chinatown was to be cleaned and disinfected under the supervision of an officer of the Marine Hospital Service, and this disinfection is now in progress.

That the existence of plague in San Francisco has been of considerable commercial loss to the State is without question. That the misfortune of the occurrence of plague in San Francisco must, in the

nature of things, have been attended with some commercial loss is obvious. The men who have maintained the existence of the disease have the interests of the State as closely at heart as have those who have opposed the diagnosis ; they differ in their convictions as to the best and least injurious method of procedure. The men who have maintained the existence of plague reason thus : Plague is here ; clinically, pathologically and bacteriologically it has been proved to be here. Under the circumstances the best method of procedure, the one affording the best protection to the public health and the least injury to the business interests of the State, is to acknowledge the truth, undertake energetic measures, and clean and disinfect 'Chinatown' in such a manner as to stamp out the disease at once. The opposition comprises two sets of men. One set does not believe that plague is here, and for them there can be no necessity for hygienic action. Though honest in their convictions, it must be insisted on that the existence of plague is a matter for scientific consideration, and is not within the scope of the judgment of business men. The second class realizes that the disease is present, but reasons that, as there are so few cases and as these are largely confined to Chinese, the situation is not serious and should be concealed in the hope that the disease will die out, and that public recognition and active hygienic measures should be deferred until the conditions become so serious that the public health is gravely jeopardized. The scientists know that there are but few cases, that the general health is not in serious danger, but believe it better to stamp out the infection while in its infancy, with the attendant small commercial loss, than to wait, in the hope that the disease will die out of its own accord, until the situation shall have become very serious, with the risk of overwhelming commercial losses in the event of a generalization of the infection.

There can be no question that the first course was the correct one. That now, one year after the trouble began, the State is compelled to do what it all along refused to do, undertake the hygienic renovation of 'Chinatown,' is an obvious proof of the correctness of the frank and open course. Had the Chinese section been promptly and effectively cleaned one year ago, the disease would have been stamped out at little cost, and the episode would have been ere this forgotten. At present the pall still hangs over California, and there is a general distrust of her on the part of the other States. We trust that the present measures will prove effective, and that the State has escaped the occurrence of a serious epidemic ; but this escape will have been purely accidental, and in matters like these a community has not the right to trust to the fortune of chance.

Conditions have apparently not been favorable to the immediate spread of the disease. This is, however, an old experience ; in many places and at many times the plague has dragged along for a long while, only to suddenly flare up into an active epidemic. The recent experience in Cape Town is a fresh illustration. The plague has been present and dragging along in

Cape Town for eighteen months; on account of the military situation, its effective eradication was neglected, and now the disease has roused into active form. It is this risk which San Francisco has been running, and this risk no community has the right to assume.

THE DESTRUCTION OF SEA LIONS IN CALIFORNIA.

PROFESSOR WOODWARD'S wholesome address on the necessity of verifying theories by the observation of facts finds an excellent illustration in the sea lion question in California. These animals, which have long been prized by lovers of nature as one of the great attractions of the coast, have fallen into disrepute among the fishermen because their presence was supposed to account for the deterioration of certain fishing grounds. So confident was the belief in their fish-devouring habits that their destruction—or at least a great reduction of their numbers—was advocated and in part accomplished by the State Commission of Fisheries. But it now appears that this belief was without substantial foundation. The appeal to fact has been made by the critical examination of the stomachs of slaughtered sea lions, and it has been found by Professor Dyche that the twenty-five animals examined had eaten only squids and other cephalopods, eschewing fish altogether. The case is suggestive of the old philosophical puzzle: Why is it that a live fish adds nothing to the weight of a bucket of water? and would be amusing but for the sad fact that the unfounded theory has already led to the killing of many of these graceful creatures.

The investigation of food-habits by means of stomach examination is of far-reaching importance. Dr. Merriam, whose letter on sea lions we print on another page, is engaged, through the Biological Survey, in the most elaborate study of animal foods ever made. For many years the stomachs of wild birds and mammals have been systematically collected and laboriously studied, to the end that the favorite and the occasional foods of each species in each season of the year, and in each part of the country, may become known. As each group is worked up the facts are published by the Department of Agriculture, and farmers and legislators are thus informed what species may properly be regarded as friendly, and what as hostile, to the interests of the people. In many instances it has been found that popular impressions, almost necessarily founded on a comparatively small number of facts, are altogether erroneous, so that war has been waged on our friends and protection given our enemies. *

*ON THE VITAL ACTIVITY OF THE ENZYMES.**

IN spite of the vast amount of work that has been done on the soluble ferments, since the discovery of diastase by Kirchoff, in 1814, the exact chemical nature of these substances is, perhaps, even more of an enigma to-day than the nature of albumen itself. Indeed, beyond the fact that the enzymes, or at least the greater number of them, are albuminous, that they probably belong to the group of nucleo-proteids and that they contain phosphorus, and probably iron, in addition to carbon, hydrogen, oxygen and nitrogen, we know but little more concerning their exact chemical composition than was known to Payen and

* In slightly different form this paper was read before the Cincinnati Section of the American Chemical Society, December 15, 1900.

Many of the biological memoirs referred to in the following were inaccessible to the writer in the original. He, therefore, desires to acknowledge his indebtedness to the following authorities: 'The Soluble Ferments and Fermentation,' Green; 'Die Fermente und Ihre Wirkungen,' Oppenheimer; 'The Cell in Development and Inheritance,' Wilson; 'Plant Physiology,' Sachs; 'Plant Physiology,' Pfeffer; Hueppe's 'Principles of Bacteriology,' Jordan.

Persoz in 1833, or to Bussy, when in 1840 he wrote that up to that time it had not been possible for him to obtain myrosin in crystalline condition. Apart from this uncertainty respecting their chemical composition, however, there has been a growing conviction in the minds of many most familiar with the peculiar and remarkable properties of these substances, that in the soluble ferments we have to deal with certain subtle and peculiar activities similar to those manifested by the living organism itself. The idea that the enzymes retain at least some vestiges of the original activity of the cell or organ of which they once formed a part is one that has appeared again and again in the scientific literature of the last twenty years with a curious persistency and under almost as many different guises as the proteid molecule itself is supposed to assume. According to Loew,* who was probably the first to advance any ideas of this kind, the enzymes are to be regarded as *active* or *labile* proteids or peptones, the activity of which is probably traceable to the presence of amido and aldehyde groups in the molecule, and whose instability is in some way connected with various molecular rearrangements involving these groups. He has also pointed out that many of the so-called protoplasmic poisons are just such substances as are known to readily attack amido and aldehyde groups in organic molecules, and it was in this connection that Loew first called attention to the silver reduction test as a means of distinguishing between active and inactive ferments and dead and living protoplasm. According to Loew† the conversion of the albumin of living into that of dead protoplasm presents a remarkable analogy to the transformation of an unstable substance into its stable modification. Such a transformation, for example, as is met with in the change of the yellow iodide of mercury into the more permanent red variety of this compound.

* Pflüger's Archiv., 27 (1882), 203, and 36 (1885), 170.

† Pflüg. A., 65, 249, 1897.

In the same way Medwedew,* like Loew, has found it necessary to assume that certain of the enzymes at least possess a residuum, as it were, of the vital forces of the living cell; and finally Armand Gautier † has gone even further in his assumptions and has taken the extreme view that the enzymes are to be regarded as *dissolved cells*, and that in addition to their other remarkable properties, they possess in common with other cells the power of assimilation and reproduction. Remarkable and suggestive as these ideas certainly are, they do not seem to have met with anything like general acceptance at the hands of biologists; indeed, in certain quarters, at least, they have encountered a very vigorous and decided opposition, and by some have been pronounced as far too vague to constitute even a satisfactory working hypothesis.‡ Apart from the fairness and justice of this criticism, there can be no doubt that, in his earlier work upon this subject, at least, Loew was inclined to lay too much stress on the silver reduction test as the basis of a sharp and accurate distinction between *active* (living) and *inactive* (dead) proteid; and while the terms *splinters of protoplasm* and *dissolved cells* may appeal very strongly to the poetical side of our nature, it cannot be denied that they are far too hazy to express with any sharpness of definition a scientific truth.

On the other hand, it would seem to the layman, particularly if he happen to be a chemist, that the whole trend of modern biology, until very recently at least, has been toward form rather than substance, and that all of the efforts of the biologist to

account for vital phenomena have been directed to the vital mechanism to the exclusion of the material substratum.

Indeed, it is not an uncommon thing to see the argument advanced that on account of their instability we can never hope to learn very much concerning the chemistry of those substances entering immediately into the composition of the living cell, for the reason that any attempt at their isolation from the cell contents at once results in their decomposition or permanent alteration. And yet the fact remains that even now at least fifty apparently distinct and different substances are known apart from, and independent of, the cell, which, in addition to some peculiar and characteristic property, such as the power to convert starch into sugar or split a fat into glycerin and a fatty acid, possess many of the more general properties and activities of the cell itself. These substances are the soluble ferments. In two very recent communications on the subject Bokorny* has given us some additional evidence of the sensitiveness of the enzymes and some additional reasons for believing in the inherent similarity between these substances and protoplasm. According to Bokorny, the sensitiveness of the ferments and their general similarity to protoplasm are to be observed in their conduct towards heat, light and the protoplasmic poisons. He therefore reaches the conclusion that the enzymes are substances similar to protoplasmic albumen, and that in all probability the two are only to be distinguished by the fact that the enzymes are wanting in organization. As the result of some recent work on certain aspects of enzyme action, the writer has been brought to see the necessity of these or similar conclusions from a somewhat independent standpoint; and, aside from their extreme instability and their delicate sensitiveness to their physical environment and to chemical reagents, the conclusion that the enzymes are active, in the sense of retaining certain of the vital activities of the living cell, would seem to derive considerable support from the following considerations:

First, their widespread and universal occurrence in all living things.

Secondly, their importance and necessity in metabolism.

Thirdly, their mode of origin.

Finally, in what follows it will be pointed out that the ferments exhibit a remarkably close analogy to the living non-nucleated fragments of the cell.

Since the discovery of diastase, in 1814, a large number of enzymes have been recognized, and what is of still greater interest and physiological significance, a large number of them, such as diastase, lipase, trypsin, etc., etc., have been found in both the vegetable and the animal organism, and, for that matter, in nearly every living cell. By means of diastase, starch is rendered available as a food-stuff both to the animal and to the plant. Trypsin occurs not only in the digestive fluids of the intestines, but is also found in the pineapple and the leaves and sap of the *Carica papaya*. The fat-splitting enzyme has been found not only in the pancreatic secretion, but also in the blood and liver and in nearly every organ and tissue of the hog. Its presence also has been proved in many seeds and seedlings. Myrosin, the mustard ferment, is found not only in the many species and varieties of Cruciferæ, but in many other natural orders of plants as well. Emulsin is another enzyme of the widest distribution in the vegetable kingdom. It has been aptly said, therefore, concerning the occurrence of the enzymes, that 'wherever life exists there also occurs the enzyme.' The one is the inseparable companion of the other. It is in connection with growth

* Chem. Ztg., 24, 1113–1114, Dec. 19, 1900; Chem. Ztg., 25, 1136–1138, Dec. 26, 1900.

and metabolism that the importance of the soluble ferments to the vital economy is seen to the greatest advantage. According to Thompson,* "The power of growth, of adding to itself substance of the same nature as itself, is the real mystery of living matter." So far as is known at present, it is mainly with growth that the enzymes are concerned. As a general thing they effect those changes which have to do with nutrition, *i. e.*, with the digestion and assimilation of food on the part of the organism. As a rule the enzymes bring about hydrolytic cleavages, the net result of which is to transform insoluble and non-absorbable reserve or food materials into absorbable and assimilable form. The transformation of starch into sugar, the change of inulin into levulose and that of cellulose into glucose, the hydrolysis of fats and the conversion of albumen into peptone, are all important and interesting examples of enzyme action. That the enzymes can also effect certain polymerizations and syntheses seems scarcely to admit any longer of a reasonable doubt; indeed, it seems not improbable, in the light of our present knowledge, that many changes hitherto looked upon as resulting from the vital activity of the living cell itself may in reality be accomplished through the instrumentality of a ferment.† Indeed it has been found that the soluble ferments stand in the closest possible relation to the vital activities of the animal and the plant. For example, Maquene ‡ has recently pointed out that the predominating, if not the only, rôle in the conservation and development of seeds must be attributed to the enzymes, and that the causes which retard the alteration and activity of the enzymes tend to maintain the germinating powers of seeds, and that, when preserved under conditions favorable to the enzymes remaining inactive, seeds may be kept indefinitely.

‡ Ann. Agron., 1900, 26, 321–332.

In this connection Sachs* long ago pointed out that the so-called dormant periods of seeds and buds are probably intervals during which the necessary ferments are being produced in the cell. The vital relation of the enzyme to the living cell is also indicated by the fact that the ferment is often produced by the cell to meet some new necessity arising from a change in external conditions or environment. For example, it has been found that the molds produce no diastatic or proteolytic enzymes so long as they are freely supplied with sugar. When cultivated on an albuminous medium, however, they speedily develop a proteolytic enzyme and on starch they soon produce diastase, and in the same connection Bernard has observed that the larva of one of the common flies, *Musca lucilia*, contains a large amount of glycogen, but no diastase. As soon as the larva passes into the chrysalis stage, however, where the glycogen is required, a diastatic ferment at once makes its appearance.

Apart from the production of several of the enzymes from their corresponding zymogens by the action of dilute acids, no enzyme has ever been produced outside of the living cell. In this connection it will be recalled that the zymogens are the mother substances of the ferments and that they in turn have never been produced outside of the living cell. In the light of these facts, the mode of origin of the ferments becomes a matter of considerable interest and importance. It has been proved that just as the nucleus and cytoplasm both participate in the formation of new cells by cell-division, so also both participate in the

* Sach's 'Plant Physiology,' 1887, p. 352.

formation of the zymogen granules, and that these, in turn, ultimately give rise to the soluble ferments. In this connection, it might be well to recall the interesting histological investigations of Heidenhain on the pancreas of the dog during the different phases of nutrition. In the case of a dog that had been fasting for a little over one day, each cell of this gland was seen to consist of two zones. The inner zone, abutting on the lumen of the alveolus, was observed to be much the larger of the two and to be thickly studded with fine granules, while the outer one, towards the basement membrane, was narrow and its substance clear and homogeneous. The nucleus of the cell was observed to be considerably shrunken and corrugated and to lie at the border of the two zones. In a pancreas of another dog, that had been killed during full intestinal digestion, the same two zones were visible. The inner granular zone, however, was much contracted and the granules much less numerous, whereas the outer hyaline zone was much wider. The cell, as a whole, had become smaller, the nucleus had regained its spherical shape and was situated near the center of the cell. These changes in the cells were observed to repeat themselves during the several phases of digestion. In the same manner other observers have been able to demonstrate a close connection between the degree of granularity of the cell and the amount of enzyme secreted. In studying the secretion of diastase by the scutellar epithelium of germinating barley, Brown and Morris were able to determine that when the secretion of diastase had ceased the marked granularity of the cells had also disappeared, and, what was even more remarkable, the nucleus of the cell had disappeared also. It would seem, therefore, that for each enzyme there exists in the gland cell a distinct antecedent substance or zymogen, ready to be transformed into the ferment the moment the latter is required. That these zymogens are not enzymes has been proved by Langley, for pepsin at least, in the most masterly and convincing manner; and the same thing has been shown for other zymogens by other equally competent observers.

The most important histological studies on the formation of the zymogens have been made by Macallum. By employing nuclear stains he was able to make out that during the formation of the zymogen a part of the chromatin of the nucleus was extruded into the cytoplasm of the cell in the form of a substance which he calls prozymogen. On coming into the cytoplasm it unites with some component thereof, as the result of which combination the granules of zymogen are produced. These granules were observed to gradually increase in size, apparently at the expense of some substance in the cytoplasmic portion of the cell. It will be observed that Macallum's view of the formation of the zymogen granules enables us to understand the shrinking and disintegration of the nucleus during secretion. It should be borne in mind, however, that in the formation of the mother substance of the ferment both nucleus and cytoplasm supply their quota.

This view of the formation of the zymogens strongly supports the conclusion that the enzymes retain a part, at least, of the original activity of the living protoplasm. In the formation of a new cell or an individual, the cell nucleus and the cytoplasm, of either the same or different cells, are involved. We have just seen, however, that in the production of the zymogen granules both the nucleus and cytoplasm participate. If, therefore, we look upon the cell nucleus as the formative and directive force in the one case, it would seem logical to so regard it in the other, the only difference being, that while upon the one hand its energies go to the forma-

tion of a new cell, on the other, they are consumed in the synthesis of an exceedingly active compound. So that scrutinize the matter as carefully as we may, we are able to see no break or discontinuity anywhere between protoplasmic activity on the one hand and the activity of the enzyme upon the other, and, originating as they do, it would be very strange indeed if the enzymes were found to be inactive substances. In this connection Langley's view on the relation of pepsin to the gland cells is highly suggestive. He says, I conceive the matter thus: "The protoplasm of the gland cells does not at one swoop form zymogen as it occurs immediately previous to its conversion into pepsin, but forms certain intermediate bodies in which the zymogen radicles become more and more isolated. Since the zymogen contains the radicle of the ferment, the ferment will be obtained with greater difficulty from the imperfectly elaborated zymogen, *i. e.*, as we ascend from the final meso state to protoplasm, the ferment will be split off less and less readily. The last traces of the ferment, then, which are obtained by repeated extractions, I take it, arise from substances which are on the way to be converted into zymogen.''* From such clear and beautiful reasoning it is but a short and logical step to the modern view of Reynolds Green,† who sees in the power to produce fermentation a fundamental inherent property of protoplasm; and who sees in the secretion of a particular enzyme 'a mark of differentiation within the living substance, just as in the slow movements of amœboid protoplasm we recognize something which in the higher and more differentiated organism appears as the contraction of muscular fiber.'

The general conduct of the enzymes is such, therefore, that if, in addition to their other properties, we could invest them with morphological characteristics and with the power of growth and reproduction, even the most conservative would, I take it, be inclined to place the soluble ferments in the category of living things. If they possess morphological characteristics, however, these are beyond the reach of the highest magnifying powers in our possession to-day; and while the enzymes exhibit certain recuperative tendencies,* they have never been made apart from the zymogen granules or the living cell, and while in perfectly dry condition they are fairly stable under ordinary conditions, their solutions speedily deteriorate, and only in a very few instances has there been observed any spontaneous

* 'The Soluble Ferments and Fermentation,' Green, p. 384.

† 'The Soluble Ferments and Fermentation,' Green, p. 371.

* The tendency on the part of the enzymes to regain their activity after they have once lost it, for any cause, is very suggestive in the light of these considerations. Bussy in his investigation of myrosin long ago pointed out that after the activity of this ferment had been destroyed by small amounts of ether or weak acids it regained the same by remaining in contact with water for 24 to 48 hours.—*Liebig's Ann.*, 34 (1840), 227.

In like manner Bokorny has found that a 0.01-per-cent. solution of formaldehyd renders malt diastase inactive for 24 hours without destroying the enzyme altogether.—*Chem. Ztg.*, 24, 1113–1114, 19/12, 1900.

Quite recently Hanriot has observed that serum lipase is rendered inactive by small amounts of free acid. After neutralization, however, the ferment regains its activity. He concludes, therefore. that the acids first combine with the enzyme to produce substances no longer capable of hydrolyzing fats, and that upon neutralization these compounds are decomposed and the ferment regenerated.—*C. R.*, 132, 146–149.

In this connection it is further interesting to note that by treatment with caustic potash Scholl was able to partially restore to blood serum the antiseptic powers which it had lost as the result of heating. At present the germicidal property of serum is believed to be zymotic. Hueppe's 'Principles of Bacteriology.' —*Jordan*, p. 86.

It is further interesting to note in this connection also that during life protoplasm shows a faintly alkaline reaction. Hammarstan's 'Physiol. Chem.' Also 'Lehrbuch der Physiol. Chem.' Neumeister.

increase in the activity of such solutions. Outside of the living cell, therefore, these substances do not seem to be able to grow or to reproduce.

In this connection it has occurred to the writer that the enzymes sustain about the same relation to the living cell as do the non-nucleated cell fragments. It has been proved as the result of numerous observations that, if a unicellular organism be subdivided by mechanical means, each fragment thereof will still manifest vital activity. To the biologist, all these fragments are alive and yet their ultimate fate may be very different. Those that are nucleated have been found to have the power of completely repairing their injuries and ultimately develop into complete cells again and reproduce by cell-division. On the other hand, while the non-nucleated fragments frequently retain their vitality for days, for example, non-nucleated fragments of the amœba have been known to live for fourteen days, they ultimately perish. In some cases the non-nucleated fragments may even heal their wounds and engulf food particles; the latter, however, remain undigested and the fragment ultimately dies without reproduction. In this connection Verworn has pointed out that a nuclear fragment entirely devoid of cytoplasm can no more regenerate the entire cell than can the non-nucleated cytoplasm alone. He is, therefore, of the opinion that the formative energy of the cell cannot derive from either the nucleus or cytoplasm alone, but from both. To him the cell itself, and not merely the nucleus, is the vital unit, the activities of which are contributed to, in part at least, by both the nucleus and the cytoplasm, and that numerous exchanges of material actually go on between them is supported by the most trustworthy histological evidence of the present day. We see thus that in the formation of a new cell, whether by the natural repair of a cell fragment or by the usual process of reproduction, both the cell nucleus and the cytoplasm are concerned. It has also been shown, however, that both the nucleus and the cytoplasm are concerned in the production of the zymogens and ultimately of the ferments. It would seem, therefore, that the enzyme and non-nucleated cell fragments stand in essentially the same relation to the living cell. Both originate in much the same manner, both lack the power of growth and reproduction, and yet both exhibit certain vital activities. Would it be far from the truth, therefore, to look upon the enzyme as the chemical basis of life?

*THE PROGRESS MADE IN ENGINEERING DURING THE NINETEENTH CENTURY.**

THE progress made in engineering during the nineteenth century, on the one hand, furnishes in itself a reminder of its ultimate dependence upon mathematics and the sciences, and, on the other hand, it attests the fact that its great and growing inspiration has been the welfare of all the civilized world. A hundred years ago but little of engineering worth or prominence was in existence; so little, comparatively, that a glance at contrasting conditions then and now will reveal striking differences.

A century ago traveling in its highest development was limited on land to the horse and coach, covering perhaps a wearisome fifty miles in a day; now a day's travel is eight hundred miles. Then, a trip from New York City to Philadelphia consumed as much time and occasioned more fatigue than one from New York to St. Louis now; or a journey then from New York to St. Louis consumed the greater

* Read before the Academy of Science of St. Louis on February 18, 1901.

part of a month at best and was considered a greater hardship than a journey to India or China now. Then, the wind furnished the sole motive power for the ships of the ocean, and a voyage took as many weeks as now it does days. A hundred years ago the great canals were not built (one making the route to India as short as was formerly the distance to the half-way point—the Cape of Good Hope); nor monolithic lighthouses erected along the coasts for the safety of ocean voyagers. Then a building three stories in height was unusual; now a sixteen-story building is not uncommon. The century has seen the chaise give place to the horse-car and this to the cable, and finally the electric car with its speedy service brings the office within easy reach of the suburban residence.

The military engineer, while still trained and ready to engage in the fiercest shock of battle, has also developed plans of hasty works to accelerate transportation and the march, to make practicable the temporary entrenchments of the battlefield or the more permanent works of encampment and the siege; and he has perfected to a high degree the many stupendous works of permanent fortification and defense. While in the preceding century architecture was considered a branch of engineering,* yet in the century just closed they have been definitely divorced.

The mine engineer has developed methods and perfected details, until the total yield of mineral wealth now each year exceeds a thousand millions of dollars, while a hundred years ago it was but a modicum. Copper has been needed for electric purposes and the arts, and he has driven adits and shafts, drifts and tunnels, until some regions are honeycombed in the search for the metal to depths exceeding a mile. The same watchful enterprise characterizes the search for other metals. But by far the most important products of the mine are coal, devoting over seven hundred million tons a year to the countless uses of commercial and industrial life, and more than seventy million tons per annum of iron and steel, whose services in the century's developments are preeminent.

* *Vide* 'Science des ingenieurs,' Belidor, Paris, 1729.

The marine engineer has developed not only the speed of ocean vessels as noted, but their safety and size as well, developing a marvel of steel construction that will contain the lading of a score of barks of a hundred years ago and carry a small city of people across the seas with a safety all but perfect. Less than a hundred years ago the first successful steamboat was built, of 4 H. P. and steaming at a rate of seven miles per hour; now the tonnage of our great steamships reaches 16,000, with a H. P. of 37,000, a length of more than seven hundred feet and a speed of twenty-seven miles per hour, while some military steamboats attain an hourly speed exceeding forty miles. A century ago the tonnage of steamships was naught; now this yearly addition to the commerce of the world is more than two million tons. Since the days of the *Clermont* and the *Savannah*, the marine engineer has been applying new discoveries and evolving improvements, slowly at first and then with increasing success, until the perfected steel giants of to-day cost about four million dollars each, instead of twelve thousand dollars for the sailing vessel of a century ago. And now there are more than fourteen thousand steamships in the world aggregating nearly twenty million tons register—a great world's fleet that, steaming abreast, would cover a width of a hundred miles.

The electrical engineer, within the latter portion of the century, has developed a field felt in all phases of practical progress, ranging from the inauguration of the telegraph of the mid-century and the submarine cable

of about forty years ago to the enormous electric stations, furnishing power for our expanding industries, turning night into day in our cities and making practicable the great development in electric traffic in urban districts, electric elevators in our stores and electric apparatus of infinite variety everywhere to minister to our needs and comforts. Through the electric transmission of power has a vast field of industry been opened. Through all the ages had great water power been useless because of its remoteness, until the development of electric machinery, suited to the purpose, made practicable the transmission of power, twenty, thirty, forty miles, with much greater distances in prospect. As indications of the inevitable result, witness the busy life in the new cotton mills of the Piedmont regions of the Southern States, or the quickened industries of the Pacific Coast.

The mechanical engineer had invented the steam engine before the beginning of the century just closed, but its development was crude, as shown by the winding and pumping engines, the sun and planet, and beam engines placed in South Kensington Museum to illustrate the practice of that day, engines which were then considered unusual if they developed one two-hundredth part of the power of engines of to-day; while the total for the world is now not far from seventy million horse-power, which is greater than the aggregate physical power of the total population of the world, even were it possible to exert this power without cessation. And the engine is only one instance of the unparalleled advance; we should also mention such inventions and developments as the cotton-gin and cotton-bailing machinery, the gas and oil engines, the harvester, the sewing machine, the hydraulic press and other hydraulic machinery, the steam-hammer, and countless other labor-saving, epoch-marking machines of wide import and far-reaching significance, like the printing press, capable now of printing, folding and counting 1,600 eight-page newspapers per minute, where the hand-press a century ago could make not more than four or five impressions in the same length of time.

The metallurgical engineer has added his full share to the increased productive capacity of the world. A hundred years ago only a pitiful modicum of iron and steel was produced, and this with great expense and almost infinite pains. The blast furnaces then were about one-half their present diameter and one-third the height, producing perhaps five thousand tons per annum, where furnaces now will produce thirty to forty times that amount. Wrought iron was produced by the Bloomery, Catalan or other crude direct processes, or by the direct open-hearth fineries of Sweden or Wales; and steel by the Catalan, cementation or crucible steel processes, likewise very expensive and slow. At the present day we have, for the production of pig iron, blast furnaces a hundred feet high, costing seven hundred thousand dollars each; and for the finished product we have the puddling furnace (first introduced by Cort close to the end of the eighteenth century), producing malleable iron, and the Siemens open-hearth and the Bessemer processes (developments of the last half-century) for the production of steel. These last two inventions mark the greatest advance ever made in metallurgical processes, and have made possible the wide range in construction in steel in all the various branches of engineering. Figures are wanting to give the quantity of steel produced a century ago. It could not have exceeded a hundred thousand tons, for fifty years ago Sheffield, then the great steel-producing city of the world, manufactured about fifty thousand tons per year; and the cost of crucible steel, made from Swedish iron, worth sev-

enty dollars, was two hundred and fifty dollars per ton. Now steel is produced at less than thirty dollars; single steel firms produce millions of tons each year, and the annual product of the world is nearly thirty million tons. To show the great growth of this interest, Sir Henry Bessemer illustrated the total production of Bessemer steel of the world by saying that if the product of a single month were made into a solid shaft of one hundred feet diameter it would reach 557 feet high. This illustration of the world's production eight years ago is now equally applicable to the United States alone, nor does it include the production of open-hearth steel, or wrought or pig iron, the total for the world approaching eighty million tons annually. There is hardly any personal, municipal or corporate life, or hardly an enterprise of war or peace, that has not more or less closely connected with its development the use of this remarkable engineering material.

In the domain of the civil engineer progress is none the less marked. Within a score of years there has been developed the tall office and other buildings of the steel skeleton type, where the engineer has had to so design the steel frame that it will support sixteen, eighteen or twenty stories, crowded with busy life and industry, as well as to bear the weight of the walls and the great wind pressures that such high buildings sometimes must sustain; and not only this, but he has so considered and controlled methods and materials in the design and in protecting this all-important steel skeleton from fire that the occupants are safer in them than in the older style of building. Steel bridges have had a longer reign, though less than forty years ago it was considered a very remarkable feat to build an iron bridge whose length of span was 320 feet. Thirty years ago the magnificent steel-arch bridge of our own city, consisting of three spans, with the central one 520 feet in length, was erected by Captain Eads. Twenty years ago the Brooklyn suspension bridge, of 1,600 feet length of span, was being constructed. Ten years ago the great cantilever bridge across the Firth of Fourth was built, containing two spans of 1,710 feet each. And now there are plans, perfectly practicable, for a suspension span of 3,200 feet, to carry eight railway tracks across New York harbor and to weigh between sixty and seventy thousand tons. In railway affairs the engineer has perfected the problems of transportation as we have seen, until the total mileage of the century is great enough to girdle the world fourteen times. In questions of water supply and sewage all our cities provide systems as a necessity, where a hundred years ago they were the luxuries of the very few, and woefully inadequate at that; and the engineer and the biologist have been colaborers in developing successful methods of preventing danger of contagion from these public utilities. Harbors and docks have been constructed and improved consonant to the spirit of the age. Foundations for great bridges and towering buildings are carried to depths requiring methods and inventions of particular resourcefulness, including the famous pneumatic processes. The development of hydraulic principles has made possible a varied series of achievements of far-reaching significance. Irrigation enterprise, which had been dead for centuries in its ancient home and was dormant even in India, has spread over the arid regions of the globe and is making oases of the waste places of the earth. In only two-thirds of the year one of the small canals of the century transports merchandise of a greater value than have the imports of China, for which the great world powers are so strenuously alert. The construction of the proposed canal from ocean to ocean across Central America will be a stupendous undertaking; humanity has never ceased to

marvel because of the great pyramids, and they have always been considered one of the wonders of the world; but, reckoned at the present cost of masonry, a dozen such pyramids could be built for the expense in-involved in the Nicaragua Canal. And when it shall be built the engineer may well improve the great waterways of the interior and build fleets of steel barges that can withstand the sea, so that our products can be sent without transhipment from our inland cities to the western coasts of the Americas. Another product of the century of significant import is Portland cement. With the aid of the chemist this material has been so improved and made accessible that now the artificial stone made from it is most widely used and is superior to most natural ones. Furthermore there is the unequivocal indication that, in combination with the all-important steel, many classes of structures of superior characteristics will be designed. Already there have been built many steel and concrete bridges which are a hundred feet in span and more, and for the Memorial Bridge at Washington, maximum spans of this construction are planned to be 192 feet each in length; while the engineer who designed it considered perfectly practicable an alternative plan of similar arches 283 feet in length. Arches of such majestic span are among the imminent constructions of the engineer.

A half-century ago Macaulay said, "Those projects which abridge distance have done most for the civilization and happiness of our species." And yet, since then, transportation facilities have increased many-fold, the first ocean cable had not been laid, nor was the telephone in use, nor other distance-annihilating inventions made. The attainment of results both definite and valuable has been in constantly accelerating ratios through all the broad field of endeavor which marks the domain of the engineer, viz., the 'direction of the great sources of power' and the development of the boundless resources of materials in nature to the use and convenience of mankind. The effect and value of this art pervade all lines of human interest and of contact, whether following Macaulay's idea of potentially bringing peoples nearer together or in the way (largely developed since his day) of rendering it possible to make life more thorough and intense by the concentration of power and of effort in great centers of activity, which is made possible by engineering structures and developments such as the towering office and industrial buildings of the last score of years; the tremendous concentrated power in steam and electric machinery of the present; the penetrating circulation of life-bringing, waste-removing water, ministering to our cities as does the blood to the body; and other examples of almost infinite variety which would cause amazement were they not so common now.

The glory and the power of the civilization of to-day result from the concentration of forces, both human and material, commanding the resourcefulness of mankind, applying the principles and discoveries of pure science, and developing the resources of nature for this purpose; and such is the degree of successful adaptation already reached, that the span of life of man potentially surpasses the millennial existences of legendary times. 'Better fifty years of Europe than a cycle of Cathay.' And the crowning glory of the measure of achievement thus far reached is that its inspiration is the welfare of the race.

MONAURAL LOCALIZATION OF SOUND.

IN the *Psychological Review* for May, 1901, occurs a detailed account of an investiga-

tion conducted by Dr. Warner Fite and the present writer upon the capacities of auditory localization in a man totally deaf in one ear. The readers of SCIENCE may be interested in a brief statement of the essential facts observed.

The subject of the experiments is a man of thirty, who lost his hearing in one ear during early childhood, as the result of scarlet fever. The present symptoms, as reported by expert clinical test, indicate total nerve-deafness and consequently lesion of the labyrinth. The drum membrane was originally destroyed by ulceration of the middle ear and a scar has now replaced it. The precise condition of the bones of the middle ear cannot be determined. The malleus appears to be intact. The uninjured ear is decidedly more acute than the average, but in no such degree as would warrant the term hyperesthetic.

Without entering into details, the apparatus employed in the experiments may be described as consisting of a mechanical device, whereby noises and tones may be given in various directions and at a constant distance from the subject's ear. The arrangement permits the exact registration, in connection with the surface of an imaginary sphere, of each location from which a sound is given. The instrument permits all the adjustments to be made noiselessly, so that the subject, who keeps his eyes closed during the experimentation, receives no suggestion whatever of the direction from which the sound proceeds. The stimuli used consisted of tuning fork tones, the tones of a Galton whistle and the snapping sound made by sending an electric current through a telephone. The tones of the forks are practically pure. The notes of the whistle are more complex and the noise of the telephone is highly complex, containing a large number of partial tones.

It will facilitate a succinct statement of the results to imagine the subject seated in the center of a large clock dial placed horizontally. The figure twelve is directly in front, the figure six behind, three is opposite the right ear and nine opposite the left ear, which is deaf. The sounds of which we shall speak first are given at the height of the ear.

Pure tones are almost, if not wholly, unlocalized by this subject. Often he can assign no position whatever to such tones, and, when he does hazard a location, the percentage and character of error show that the process is extremely inaccurate. On the other hand, complex sounds are localized with an accuracy which follows closely the number and audible nature of the partial tones they contain. The one exception to this is the region lying between eight and ten on the face of our illustrative dial. This is the region immediately opposite the deaf ear. To offset this defect the discrimination between positions immediately in front and those directly behind is superior to that of normal persons, for whom this distinction is notoriously uncertain. For the remaining regions, from ten toward the right around to eight, the localizations are only slightly inferior to those of normal individuals. Occasional confusions of the right and left hemispheres occur, which are almost unknown to binaural hearing. But in general, both as regards the character of the error and as regards the amount, the localizations are surprisingly like those of the binaural type.

In normal persons the localization of sounds is commonly supposed to depend upon the differences in the stimulations reaching the two ears. These differences are describable as partly differences in intensity and partly differences in quality. Thus, a sound opposite the right ear, for example, stimulates that ear more intensely than it does the left ear, and, if it be a complex sound, more of its component overtones will be noticeable to the right ear

than to the left, so that qualitatively it will be perceived as different from the same sound when heard directly in front. In the case of monaural hearing it is clear that the intensity of a sound can afford only the most ambiguous information. An apparent change in intensity in such a case may mean change of distance, change of direction, change of actual intensity or some combination of these alternatives. But the single ear is by no means so helpless as regards the detection of qualitative differences due to changes of direction. Our subject himself connected his capacity to localize sounds with this noticed change in quality. His results show that (although in every case he remained ignorant of his success or failure during the experimentation) he possessed to begin with a relatively accurate auditory orientation on the basis of these qualitative peculiarities of sounds due to their direction, and, furthermore, that after gaining a little familiarity with the sounds, his localizations became very accurate. Nor did he seem to find any serious difficulty in determining direction, when the absolute distance of the sounds was varied, nor yet when the absolute intensity was varied. Pure tones he could not localize for they undergo no qualitative modifications by change of direction. Intensity changes are the only ones of which they are susceptible. Slightly complex sounds he can localize fairly. Highly complex sounds, possessing component tones well inside the range of ready detection, he can localize extremely well, save in the region just opposite the deaf ear. The same statements hold for localizations above and below the equatorial plane, to which we have confined our description. The modifications met with outside this plane are all conformable to the fundamental theory of the dependence of the localizations upon qualitative differences in the sounds. The pinna, the meatus, the bones of the head, etc., all contribute to the production of these qualitative modifications.

FOOD OF SEA LIONS.

THE California State Board of Fish Commissioners during the past two years has taken steps to kill off a very large number of sea lions on the California coast, on the ground that these animals are highly destructive to the salmon fishery. The president of the board, Mr. Alexander T. Vogelsang, claims that it is not the intention of the board to exterminate the sea lions, but merely to kill '10,000 of the 30,000 that now infest our harbor entrance and contiguous territory.'* The opinion of observers familiar with the sea lion rookeries is that the number of animals has been greatly exaggerated, and that long before Mr. Vogelsang has killed the contemplated 10,000 there would not be a living sea lion left on the whole coast. Already many have been killed and, unless public sentiment is aroused to check the movement, some of the most interesting rookeries of the State are in danger of depletion. The Fish Commissioners have employed men to shoot the sea lions, and are loud in their lamentations because the Government light-house reservations have not been thrown open to the slaughter.

The local fishermen, the State Fish Commission and others assert without qualification that the sea lions feed extensively on salmon, and the inference from their statements is that the animals subsist chiefly, if not entirely, on fish. A few years ago, when similar complaints were made against the fur seals, I took the trouble to examine the stomach contents of a large number of these animals, and found to my surprise

*In letter to Hon. Lyman J. Gage, Secretary of the Treasury, dated San Francisco, June 3, 1899.

that the great bulk of their food consisted of squids, hundreds of whose beaks and pens were found in the stomachs, while in only a few instances were any traces of fish discovered.

In 1899, a well-known naturalist, Prof. L. L. Dyche, of the University of Kansas, spent the months of June, July, August and September on the California coast, at a time when the sea lions were being slaughtered in the alleged interests of the fishermen. Professor Dyche became interested in the question of their food, and took the trouble to examine the stomachs of 25 sea lions, not one of which contained so much as a trace of fish. The region visited extends from Monterey Bay southward along the coast for about 25 miles.

Between June 25th and July 16th, there were washed ashore within three miles of Point Pinos, at the mouth of Monterey Bay, eight sea lions which had been shot, the fishermen said, because they were feeding on salmon. Professor Dyche examined the stomachs of all of these and has given me a detailed record of the contents of each. It would take too much space to print this in full. Suffice it to state that the remains of squids and cuttlefish (*Octopus*) were found in all, and that several were filled with large pieces of the giant squid. Notwithstanding the fact that at the same time and place salmon were being caught by fishermen, not a fish scale or bone was detected in any of the stomachs. Whenever possible Professor Dyche opened the stomachs in the presence of the fishermen, who invariably expressed the greatest surprise at the result. On July 20th, Professor Dyche moved his headquarters southward and established a camp about twelve miles below Monterey Bay, between Point Carmel and the lighthouse, near which is an extensive rookery of sea lions. Between July 20th and August 16th, the stomachs of seventeen additional sea lions were examined. Eight out of the seventeen were well filled with the flesh of the giant squid; two were gorged with large octopus, while the remaining seven contained pens and beaks of squids, the quantity varying from half a pint to about a quart.

Professor Dyche was told that there were no fish within two or three miles of the sea lion rookeries near his camp, as the sea lions had caught or driven them away. In the face of this statement, he himself caught a dozen rock cod one morning between shore and the seal rocks, and his boatman, George Carr, an old salmon fisherman, caught plenty of rock cod weighing from one to eight pounds each, within sixty feet of the flat rock where from one to 300 sea lions landed each day. The water close to these rocks, where the sea lions had lived for ages, proved to be the best fishing ground in the locality. Professor Dyche states further that he landed a number of times on the rocky islands where in places the excrement from the sea lions formed a layer a foot thick. He hunted through this for fish bones and scales, without being able to discover a single one. On the other hand, the tough pens from the backs of the squids were abundant.

Professor Dyche found the fishermen loud in their denunciation of the sea lions on account of their alleged destruction of salmon, but, although he was on the fishing grounds continuously for more than three months, the fishermen were unable to show him a single instance in which a sea lion had killed a salmon. He adds, "You can hardly imagine the surprised look on these fishermen's faces when they saw the great masses of squid meat roll out of the sea lions' stomachs when cut open."

The fact that sea lions in captivity will eat fish rather than starve has little bearing on the question, and the additional fact that salmon in nets are sometimes found bitten off or eaten is by itself no evidence

at all, particularly in places where either sharks or otters occur.

It is not claimed that sea lions in their native element never eat fish; at the same time the only actual evidence we have on the subject fails utterly to substantiate the allegations of the fishermen. On the contrary, all of the twenty-five stomachs of sea lions examined by Professor Dyche contained remains of squids or cuttle fishes, and not one contained so much as the scale or bone of a fish. And is it not significant that in former years, when sea lions were much more plentiful than now, salmon also were vastly more abundant? If the fishermen will look into their own habits and customs during the past twenty-five years, it is believed that the cause of decrease of the salmon will not be difficult to find, and this without charging the decrease to the inoffensive sea lions, whose rookeries constitute one of the greatest attractions to the visitor on the California coast.

C. HART MERRIAM.

SCIENTIFIC BOOKS.

The Seri Indians. By W J McGEE. Extract from the Seventeenth Annual Report of the Bureau of American Ethnology. Washington, Government Printing Office, 1898 [1901]. Pp. 344, with 62 plates, and 42 figures in the text.

Seldom has one to chronicle the appearance of a work so thoroughly 'a contribution to human knowledge' as is this modestly titled essay. Brinton, in his 'American Race' (N. Y., 1891), styles the Seris 'a Yuma folk,' and consecrates a few lines to the enumeration of their not very prepossessing characteristics. Indeed, although these Indians came into contact with the whites in 1530–1540, they remained till towards the close of the nineteenth century perhaps the least studied of all the North American aborigines. The expeditions sent out in 1894 and 1895 by the Bureau of American Ethnology, under the efficient leadership of Dr. McGee, have resulted in the shedding of a flood of light upon one of the most interesting and remarkable groups of savages on the globe. After a brief introduction dealing with the salient features of the people, geographical nomenclature, etc., come sections on habitat (pp. 22–50), summary history (pp. 51–122); tribal features—nomenclature, external relations, population (pp. 123–135); somatic characters—stature, color, etc., skull, skeleton, pedestrian habit, fleetness and endurance, absence of 'knife sense,' race sense, cheirization, alternation of states (pp. 136–163); demotic characters—symbolism and decoration, industries and industrial products, social organization, language (pp. 164–344). Throughout these pages one is made aware of that noteworthy combination of keenness of perception and aptness of expression, that harmonious unity of the explorer and the recorder, which make the author's anthropological publications rank with the most suggestive and most stimulating scientific literature of the day.

The Seris (the word is Opata and means 'spry'), or, as they call themselves (by a name including fire and the animal world) *K^m káak*, 'our-great-mother-folk-here,' inhabit Tiburon Island (some 30 miles in length by from 12 to 20 in width) in the Gulf of California, and a limited adjacent area on the mainland of the Mexican State of Sonora. Two centuries ago they are said to have numbered several thousands, but almost uninterrupted warfare has reduced them to some 350, of whom not more than 75 are adult males or warriors; and, notwithstanding the fact that, under the renewed isolation of the last decade or two, they seem to have rallied their strength a little, or at least to have held their own, Dr. McGee holds out to us no other prospect than the 'early extinction of one of the most strongly marked and distinctive of aboriginal tribes.' In the historical summary the chief events in the contact of Caucasians and Seris, with their terrible results, in so far as the latter are concerned, are outlined, the concessions (now reported) of Seri territory to American speculators may be the beginning of the end. If so, the Seris will not have passed away without meeting an able and sympathetic chronicler. The importance of Dr. McGee's monograph for those engaged in the study of the phenomena of heredity and

environment, of somatic and mental relationship, of tribal and individual expressions, of isolation and *Wanderlust*, of race antagonisms and human affections, of labor and repose, of the matter-of-fact and the mystical, can hardly be exaggerated, since, as he claims, with seeming justice, 'the Seri must be assigned to the initial place in the scale of development represented by the American aborigines, and hence to the lowest recognized phase of savagery' (p. 295). The environment of the Seris consists of the broad Desierto Encinas (the eastern boundary), the mountainous zone of Sierra Seri, Tiburon Island (with adjacent islets), the navigable straits and bays about the islands and the mainland. The mainland is a sort of a dependency, for Tiburon Island (the eastern shore especially) is the real home of the Seris. To their dwelling chiefly on the prolific seashore of Tiburon Dr. McGee attributes the fact that the Seris 'never learned the hard lesson of desert solidarity,' and so have 'held aloof from that communality of the deserts which has brought so many tribes into union with each other and with their animal and vegetal neighbors through common strife against the common enemies of sun and sand—the communality expressed in the distribution of vital colonies over arid plains, in the toleration and domestication of animals, in the development of agriculture, and eventually in the shaping of a comprehensive solidarity, with the intelligence of the highest organisms as the controlling factor' (p. 133). The isolation of the Seris is reflected in their enmity towards aliens—the Papagos, the Yaquis, the Caucasians—an enmity which removes them in thought and life from all contemporaries so that 'they far out-Ishmael the Ishmael of old on Araby's deserts.' The local antipathy is even greater than the race antagonism for the whites, who have been sometimes tolerated for a time as food-bringers or wonder-workers. This antagonism amounts to obsession, and is 'crystallized into a cult'; yet among themselves, we are told, 'they were fairly cheerful, and the families were unobtrusively affectionate'—maternal affection, especially, is strong.

The waters about Seriland, as some of the Spanish names—El Infiernillo, Sal-si-puedes, etc.—indicate, are very stormy and dangerous to navigation, but 'the fierce currents and frequent storms of the region * * * have undoubtedly contributed to the development of the peculiarly light, strong and serviceable water-craft [balsas] of the aboriginal navigators among the islands' (p. 45). The primary resource of Seriland is potable water, and the springs and water-holes are few and far between. Yet it is the tribal policy (based perhaps on military instincts) to 'locate habitations in places surprisingly remote from running water' (p. 183). This has naturally developed the water-industry, and it is not strange that the Seris 'are essentially and primarily water-carriers, and all their other industries are subordinated to this function.' As remarkable as their conquest of the stormy sea is the Seri invention of an olla or water-jar, which, in so far as capacity is related to weight of vessel, is about twice as economical as the corresponding ware of the Pueblos or the Papagos. These Indians seem to have conquered the desert also in this respect. The basketry of the Seris is likewise of very noticeable lightness.

Among the most striking physical characteristics of the Seris are 'the noble stature and erect yet easy carriage,' the dark color of the skin, breadth and depth of chest, 'slenderness of limbs and disproportionately large size of extremities (especially the feet),' long and luxuriant hair, and 'a peculiar movement in walking and running.' But a single Seri skeleton has been scientifically studied, and the details of the measurements, as given by Dr. Aleš Hrdlička, occupy pages 141–147 of the work under review. The skeletal facts confirm the deductions from the living body as to the slowness of the organism in attaining maturity—somatic growth continues 'throughout an exceptionally long term in proportion to other stages in the life of the individual.' The range of variation in stature, color, etc., is less than is the case with neighboring Indian tribes. The segregative habit and antagonism to aliens—'protean manifestations of race-pride'—amount to what Dr. McGee calls *race-sense*. Indeed, the Seri are so close to each other and so far from all others that a member of the tribe 'can no more

control the involuntary snarl and growl at the approach of the alien than can the hunting dog at sight or smell of the timber-wolf' (p. 155). The pedestrian habit and the adaptation of the body in its movements (simulating almost the antelope) to the needs of progression in a particular environment, are quite remarkable, and the skill of the Seri runners, like their swiftness of foot, is almost incredible—in men, women and children, the pedestrian art is highly developed. Another conspicuous peculiarity of these Indians is 'habitual use of hands and teeth in lieu of the implements characteristic of even the lowly culture found among most primitive tribes.' They practically lack the 'knife sense,' and are, moreover, conspicuously unskilful in all mechanical operations involving the use of tools. Seri warriors are said often to have recourse to tooth and nail in battle.

Except face-painting, which is practically confined to the female members of the tribe (being of blood-marking significance; the 'elder-women' are very prominent), and recalls the markings of animals, decoration or tangible symbolism is rare among the Seris. Not only are these people less advanced in æsthetic development than other American Indian tribes, but they are also 'at the bottom of the scale in the ratio of æsthetic to industrial motives' (p. 176).

A dearth of fishing tackle is also noted, but in the capture of the sea-turtle (a most prominent article of diet), the adaptation of means to ends is beautifully illustrated: 'The graceful and effective balsa is in large measure an appurtenance of the industry; the harpoon is hardly heavier and is much simpler than a trout-fishing tackle, yet serves for the certain capture of a 200-pound turtle; and the art of fishing for a quarry, so shy and elusive that Caucasians may spend weeks on the shores without seeing a specimen, is reduced to a perfection even transcending such artifacts as the light harpoon and fragile olla' (p. 189). The ingenious use of the young or crippled pelican, as an aid in the procurement of food may possibly have been borrowed from other California tribes. The arrow, the weapon of the chase, is, perhaps, even more notably perfected than the harpoon. Between the arrow and the harpoon, on the one hand, and the fire-drill on the other, there is a remarkable structural homology, the harpoon having been in all probability the primary device. With the Seris, the bow has now replaced the atlatl, or throwing stick formerly in use. In contrast with the arrow, the bow is a rude and clumsy device. The posture of the Seri archer is one of the most remarkable known. The development of the hunt has apparently 'blinded the Seri to the rudiments of agriculture,' and goes far to explain 'their intolerance of all animal associates, save the sly coyote that habitually hides its travail and suckling in the wilderness, and perhaps the deified pelican' (p. 203). The hunting of the horse is an acquisition of post-Columbian date, in which these Indians have developed rare skill.

As to food, the Seris are omnivorous, and their systematic scatophagy—the 'second harvest' of the tuna is carefully stored—gives them almost a bestial character, though in this peculiar practice the beginnings of a thrift-sense and the germs of industrial economy are possibly to be seen. The 'houses' of the Seris are of the rudest sort, merely shelters adapted to the roving needs of the tribe, but it is very interesting to learn that 'placing and fitting of the beams and tie-sticks are accompanied by a chant, usually led by the eldest matron of the group,'—for women are the builders here. The chant is probably a very primitive 'worksong' of the sort Professor Bücher has recently discussed. The absence of the breech-clout (so common an article of primitive clothing) is, Dr. McGee thinks, accounted for by conditions of environment making 'the free-flowing and easily removable apron' of most service as a protective dress. An autochthonous dress of the Seris is the pelican-skin kilt, while as cords, fasteners, etc., fabrications of human hair are abundantly employed.

In so far as their peaceful industries are concerned, the Seris are among the most primitive of known tribes, and 'combine the features of the zoomimic and protolithic stages more completely than any other known folk, and in such wise as to reveal the relations between these stages and that next higher in the series with

unparalleled clearness' (p. 253). Their implements of stone reflect the conditions of their habitat remarkably well.

Seri warfares, like the hunting customs of the tribe, is 'largely sortilegic,' and the warfare of the tribe (devoid of military tactics in the strict sense of the term) is 'merely an intensified counterpart of their chase' (p. 261). To the 'blood-craze' of the hunters corresponds the 'war-frenzy' of the fighters. Poor in offensive and in defensive devices, the Seri Indians, apart from the natural conditions of their habitat, find their effective protection in 'their fleetness coupled with their habitual and constitutional timidity.' The famous 'poison arrows' of the Seris are discussed at pages 255–261, and a description given of the loathsome mess compounded by the medicine-man for tipping them.

The most interesting fact in Seri sociology is 'prominence of the females, especially the elderwomen, in the management of every-day affairs' (house building, transportation of family property, regulation of personal conduct, productive labor, shamanism, proprietary affairs, legislative and judicative functions, etc.). The social unit appears to be the maternal clan, with certain modifications and additions due to the general feeling of the tribe, the clan-mother being the central figure of the group, but the executive power residing in her brothers in the order of seniority. In other words, 'while the personal arrangement of the group is maternal, the appellate administration is fraternal' (p. 275). The contests for the chiefship are sometimes very protracted, but 'the choice really reflects physical force.' The process of adoption, so important generally with primitive peoples, seems 'entirely foreign to the thoughts of the tribe,' only a few sporadic and uncertain cases being on record. Since there is a surplus of women among the Seris, polygamy naturally prevails, although the practice is perhaps incidental and of comparatively recent origin. Of the sexual unions of these Indians the author remarks (p. 279): 'The primary mating of the Seri is attended by observances so elaborate as to show that marriage is one of the profoundest sacraments of the tribe, penetrating the innermost recesses of tribal thought, and interwoven with the essential fibers of tribal existence. Few, if any, other peoples devote such anxious care to their mating as do the Seri [the author compares them with the Australian aborigines]; and among no other known tribe or folk is the moral aspect of conjugal union so rigorously guarded by collective action and individual devotion.' The premarital tests are severe, and the conditions of the probationary period are such as to demand indubitable proof of control of sexual passion. Of the mortuary customs of the Seris, the most remarkable feature is 'the special dignification of females in respect to funerary rites,' something without exact parallel among other American aborigines. Traces of at least an inchoate belief in a future life, and of strong veneration for, or fear of, the spirits of the departed (matrons in particular), were noted, as indeed is indicated by certain funeral customs.

The Seri linguistic material was submitted to Mr. Hewitt, of the Bureau of American Ethnology, whose thorough-going comparative study (rather too decided, perhaps, in some respects) occupies pages 299–344. The result is to settle the status of Seri speech as an independent tongue, and not a Yuman dialect, as some have thought. Taken altogether, the Seri mind shows itself to be 'local, chance-dominated, exceeding lowly, and especially autochthonal in its contents and workings.' The author's views as to the meanings of the correlation of race-sense and stirpiculture are of great interest to all students of racial and individual development (p. 162): 'Even if the measure of the incarnation of ideals be reduced to the lowest maximum consistent with human knowledge it remains true that the progeny of successive generations are not the offspring of average parents, but of pairs at the perfection and conjugal culmination of their virile and muliebrile excellencies; so that the generations must run in courses of cumulatively increasing racial (or human) perfection, under a general *law of conjugal conation*.' Well, indeed, do the Seri Indians illustrate the incarnation of primitive ideals, as indeed the Greeks once did, and with not such moral descent as the latter sustained.

Another general fact concerning the Seris, of great importance to the psychologist, and

suggesting at once comparisons with childhood and the phenomena of genius, is the marked alternation of intense activity and complete repose—activity measured by hours, intervals of rest measured by days. Equally noteworthy is the rapidity of change from one state to the other. According to Dr. McGee, "the Seri are at once the swiftest and the laziest, the strongest and the most inert, the most warlike and the most docile of tribesmen; and their transitions from rôle to rôle are singularly capricious and sudden" (p. 156). This throws a new light upon the question of savage laziness and hints how unfair some of the earlier writers have been in picturing primitive man as uniformly inert. This essay is emphatically a valuable addition to the scientific literature about primitive man. The appearance of the author's companion study of the Papagos will be awaited with great interest.

ALEXANDER F. CHAMBERLAIN.
CLARK UNIVERSITY,
WORCESTER, MASS.

Verhandlungen der deutschen Zoologischen Gesellschaft auf der zehnten Jahresversammlung zu Graz, den 18 bis 20 April, 1900. Im Auftrage der Gesellschaft herausgegeben von Prof. Dr. J. W. Spengel, Schriftführer der Gesellschaft. Mit in den Text gedruckten Figuren. Leipzig, Verlag von Wilhelm Englemann. 1900. Pp. 170. Preis M. 6.

The most important matter brought before the tenth meeting of the German Zoological Society at Graz was the report of Professor Franz Ellhard Schultze, editor-in-chief of *Das Tierreich.* The year preceding the report witnessed the publication of several sections of this great work upon systematic zoology, the most notable being that of Labbé upon the 'Sporozoa' and that of Michaelson upon the 'Oligochæta.' That substantial progress will be made in the near future is seen in the fact that the following manuscripts were ready for the press: 'Hydrachnida' by Piersig, 'Halicarida' by Lohmann, 'Nemertina' by Bürger, the first division of the 'Amphipoda' by Stebbing, the 'Palpigrada' and 'Solifuga' by Kraepelin, the 'Libytheida' by Pagenstecher. The following sections are now in the process of editorial revision: calcareous sponges by Breitfuss, the second division of the 'Copepoda' by Giesbrecht and Schmeil, the second division of the 'Decapoda' by Ortmann, the first division of the 'Formicida' by Emery, the 'Pneumonopoma' by Kobelt, the 'Rodentia' by Trouessart, the 'Rhizopoda reticulosa' by Rhumbler, and the first division of the 'Apida' by Friese.

To insure prompt publication of the accumulating manuscript is a problem for whose solution the recommendation is made that a competent 'Superreviser, Secretar, and Bureauchef' be appointed to assist the editorial bureau in the laborious work of securing uniformity in matters of terminology, nomenclature and bibliography, and to maintain the unity of this monumental work which the German society has undertaken. Arrangements were consummated whereby in the future the *Tierreich* will be issued conjointly by the Society and the Royal Prussian Academy of Sciences, as will be shown by the title page of future issues.

The principal address of the session was given by Professor Karl Heider on 'Das Determinationsproblem,' a masterly review of the whole subject of experimental morphology. In a second paper Professor Heider calls attention to a new and strange genus of trematodes parasitic in the dolphin. This new type, *Braunina,* is peculiar in possessing a pedicel and a mantle developed to a degree hitherto unknown in the group, while suckers are entirely lacking.

Herr Künkel has investigated the capacity of *Limax* for the absorption of water which enters the body not only through the mouth, but also through the skin by absorption. The volume of the slug may be increased by this process as much as 209% while the specific gravity is correspondingly decreased and feeding activities are suspended until the water is reduced. The consumption of oxygen in respiration was studied and the rate of exhaustion of the air was found to be 0.36 ccm. per hour for each cubic centimeter of the slug's body. The respiratory process is carried on not only in the air-chamber, but also on the surface of the body.

Dr. Hans Rabl finds no evidence to support the ectodermal origin of the pigment cells in embryos of cephalopods. From their first

appearance the chromatophores are found *only* in the mesoderm. They are single cells with a single large nucleus, appearing to be multi-nuclear only when in degeneration they are invaded by adjacent connective-tissue cells. The author explains the expansion of the cells by the contraction of the radial fibers around it and its contraction by the elasticity of the cell membrane.

Other papers are by Herr Thon on 'The Copulatory Organs of the Hydrachnid Genus *Arrhenurus* Dugès'; by Dr. Doflein on 'The Inheritance of Cell Characteristics'; by Dr. Simroth on 'Self-Fertilization in Pulmonates'; by Dr. Escherich on 'The Germ Layers in the Muscidæ'; and a history and description of the Graz 'Zoologisch zoolomische Institut,' by Professor L. v. Graff.

The excursion of this session was made to the Austrian Zoological Station at Trieste founded twenty-five years before, largely through the efforts of Professor F. E. Schultze. Since the retirement, in 1896, of Professor Carl Claus, director of the station for many years, the control of the enterprise has been in the hands of a board representing the leading Austrian universities. With the change has come renewed activity, an enlarged building and increased equipment.

CHARLES A. KOFOID.

UNIVERSITY OF CALIFORNIA.

A Select Bibliography of Chemistry 1492–1897. By HENRY CARRINGTON BOLTON. Section VIII. — Academic Dissertations. City of Washington: published by the Smithsonian Institution. 1901. Pp. iv + 534.

This volume—number 1253 of the Smithsonian Miscellaneous Collections—is the third in Dr. Bolton's 'Bibliography of Chemistry.' It is devoted exclusively to those academic dissertations which have been printed independently, and especially to those from the universities of France, Germany, Russia and the United States. The number of the last is exceedingly small, for it seems not yet to be the custom of most American universities to require the printing of theses for the doctor's degree, although much of this work finds its way sooner or later into periodical literature. About seven thousand dissertations are catalogued in the volume, about four-fifths of the titles being German, and a large share of the remainder French.

The reviewer has been interested in tabulating the results of an examination of sample pages, scattered uniformly through the book. From this it appears that nearly five thousand of the dissertations are from German universities, slightly more than a thousand from French, and perhaps seven hundred and fifty from the Swiss, schools. Of the German universities, Erlangen, Berlin, Göttingen and Leipzig stand first, each furnishing about five hundred titles, while Freiburg and Heidelberg stand considerably lower, and are not very closely followed by Rostock, Tübingen, Jena and Würzburg. Of the Swiss universities, Zürich furnishes about as many titles as Rostock, and Berne as many as Jena. More than half the French dissertations are from l'École de pharmacie de Montpellier, most of the remainder being from Paris and from l'École de pharmacie de Paris, those from the latter being rather more in number than from the former. One hundred and thirteen titles are in Russian, and perhaps nearly as many more are from the University of Dorpat.

This glance reveals to us the position which Germany occupies in the teaching of chemistry, and, if the dissertations of the last few years alone were considered, it would be found that France stands much lower than is shown by the figures above.

Dr. Bolton will receive the thanks, especially of all chemists who are engaged in research, for this addition to his many valuable contributions to bibliography, for it affords access to a very important field of chemical literature, which, for want of an index, has hitherto been practically closed. The original dissertation is often of far more value to the investigator than the re-edited work which appears in the journals. The value of this book is still further increased by reference to those dissertations which are in the libraries of the Geological Survey and of the Smithsonian Institution; and also—this would certainly be missing in no book of Dr. Bolton's—by a very complete index, which fills ninety double-column pages.

While this volume completes the undertaking

begun by the author in 1888, of preparing a 'Select Bibliography of Chemistry,' he has now in preparation a fourth volume, which will afford him an opportunity of supplying omissions in the three already published.

JAS. LEWIS HOWE.

WASHINGTON AND LEE UNIVERSITY,
LEXINGTON, VA.

Elementary Organic Analysis, The Determination of Carbon and Hydrogen. By FRANCIS GANO BENEDICT, PH.D., Instructor in Chemistry in Wesleyan University. Easton, Pa., The Chemical Publishing Co. 1900. 8vo. Pp. 86. Price $1.00.

The author states in his preface, "Perhaps no analytical operation is at once so fundamentally important and exasperatingly vexatious as the organic combustion. Notwithstanding this fact, save for the meager statements in one or two of the larger books on organic chemistry, no description of the process of the determination of carbon and hydrogen is accessible to most students. As a rule a knowledge of the operation is chiefly obtained by word of mouth.

"This little manual is presented in the hope that the descriptions of processes here recorded will aid in making this method of analysis more familiar and more satisfactory."

The author states that he has had an experience with over two thousand combustions and that in this book he has embodied such modifications of the general method as have been suggested by that experience.

Some idea of the book will be obtained from the following table of contents: Introduction, preparation of oxygen, compressed oxygen, gasometers or gas holders, air, purifying apparatus, rubber tubing and stoppers, combustion furnaces, combustion tubes, oxidizing agents, filling the combustion tube, boats, absorbing agents, absorbing apparatus, cleaning and weighing absorbing apparatus, weight of material used, burning out the combustion tube, general process of the combustion, combustion of nitrogenous substances, combustion of bodies containing the halogens, combustion of bodies containing sulphur, combustion of bodies containing the alkali metals, combustion of difficultly combustible bodies, combustion of liquids and volatile bodies, combustion of explosive bodies, calculation of results, appendix and index.

The book is well printed and of convenient size for laboratory use. For use in teaching students of chemistry the methods of combustion analysis it will be of great value, and even the experienced chemist will find in it many suggestions and new ideas.

W. R. ORNDORFF.

SCIENTIFIC JOURNALS AND ARTICLES.

The American Naturalist for April has as its first article a paper by B. Arthur Bensley, on 'A Theory of the Origin and Evolution of the Australian Marsupialia.' The adaptive modification of their teeth and feet are compared with those of placental mammals, the author concluding that the marsupials were differentiated from Didelphyd forms, but adding no evidence to show from what direction they entered Australia. R. M. Strong presents in detail 'A Quantitative Study of Variation in the Smaller North American Shrikes,' and Frank Russell describes 'A New Instrument for Measuring Torsion' in the long bones of the human skeleton, but applicable to other purposes. The valuable series of 'Synopses of North-American Invertebrates' is resumed, the present paper, the fourteenth of the series, by C. W. Hargitt, being devoted to 'The Hydromedusæ, Part I.' The number contains the quarterly record of gifts to institutions, and the appointments, retirements and deaths of scientific workers.

The Journal of Physical Chemistry, March, 1901, 'On the Dielectric Constants of Nitrils,' by Herman Schlundt. The fact that solutions

of salts in nitrils are good conductors of electricity makes a determination of the dielectric constant of importance. Hydrocyanic acid was found to have a higher dielectric constant than water. An increase in the size of the molecules of nitrils by the addition of carbon and hydrogen lowers the dielectric constant. 'The Fundamental Equation of a Multiple Point,' by Paul Saurel. 'On a Property of the Pressure-Volume Diagram,' by Paul Saurel. 'Dissociation Studies,' by Wilder D. Bancroft. A study of the equilibrium relations of the three modifications of ethyl-aldehyde.

The April number (No. 2, Vol. XXIII.) of the *American Journal of Mathematics* contains the following memoirs: 'The Cross Ratio Group of 120 Quadratic Cremona Transformations of the Plane,' by H. E. Slaught; 'Memoir on the Algebra of Symbolic Logic,' by A. N. Whitehead; 'On a Special Form of Annular Surfaces,' by V. Snyder; 'On the Transitive Substitution Groups, whose Order is a Power of a Prime Number,' by G. A. Miller; 'Geometry on the Cubic Scroll of the Second Kind,' by F. C. Ferry.

The leading article of the May number of *Popular Astronomy* is the concluding one of the series written by Herbert A. Howe, on 'Astronomical Books for the Use of Students.' G. Seneca Jones contributes a discussion of Professor Holden's recent article in *McClure's Magazine*, entitled 'What we Know about Mars'; George C. Comstock an article on 'Establishing a Meridian Line,' and Dr. J. Morrison the third instalment of a series on general perturbations and the perturbative function. 'The New Star in Perseus' is discussed by A. E. Douglass, of the Lowell Observatory, Flagstaff, Arizona, and by George E. Hale, of the Yerkes Observatory, and Professor J. G. Hagen's second chart and catalogue are printed. Observations are reported by David E. Hadden, F. E. Seagrave and Wm. E. Sperra. Dr. H. C. Wilson writes of the approaching total solar eclipse of May 17–18, 1901, accompanying his article by charts showing the path of the eclipse and its track across Sumatra and Borneo. The General Department contains notes upon Amherst College Total Eclipse Expedition, the Benjamin Apthorp Gould fund, Eros a Double Planet, Astronomy in High Schools, List of Stellar Novæ and So-called New Stars-Book, reviews of Serviss, 'Pleasures of the Telescope,' and Comstock's 'Text-Book of Astronomy,' 'Astronomy in the 20th Century' and the Alvan Clark and Sons Corporation. The usual planet and asteroid notes are also included.

SOCIETIES AND ACADEMIES.

ANTHROPOLOGICAL SOCIETY OF WASHINGTON.

At the 317th meeting, held on April 9th, Mr. George C. Maynard exhibited an interesting series of early time-keeping apparatus, consisting of a set of four sand glasses, mounted in a frame, used during the fourteenth century in churches; a water clock; a pewter and glass time lamp; a time candle, and a small cocoanut cup from Lower Siam, having a perforation; the cup, when floated on a basin of water, sinks in a stated period.

Hon. Edward F. McSweeny, Assistant Commissioner of Immigration, port of New York, read a paper on the immigration question. The paper was accompanied by charts and photographs of racial types. Mr. McSweeny, in discussing the subject of immigration, gave some historical account of the origin and cause of such movements, and, in reference to the tide that early set toward this country, he called attention to the variety of peoples that were represented. In the chart showing immigration by years, the diminution of the influx of foreigners during the periods of industrial depression was most marked. Mr. McSweeny pointed out that the foci of immigration have shifted from northern Europe to eastern Europe, and that the bulk of immigrants are Italian, Slavic and Oriental, of an undesirable class. He fears that the present tendency to concentration in all fields of industrial endeavor may be utilized in connection with the introduction of vast hordes of these aliens to break down labor conditions and wage standards, and suggests that legislation to exclude this undesirable class should be framed. The paper was discussed by Major J. W. Powell, John R. Proctor, and a number of others present.

Walter Hough.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

THE 535th regular meeting was held April 27th, President Walcott in the chair.

Mr. I. M. Cassanowicz, of the National Museum, presented an interesting paper on 'The Funerary Rites of the Ancient Egyptians.' He said the monuments and remains of ancient Egypt are chiefly of a sepulchral character. The Egyptians believed in a personal existence after death. Their conception of the conditions and localities of the future existence was vague, but these seem to have been patterned after the conditions known in Egypt: the dead formed a nation who worked for Osiris as for a Pharaoh. As the Egyptians could not conceive of existence apart from a tangible substance, a link was needed to connect the *Ka*, the representative of personality, with the world of substantial things; this link was the body, and so its preservation was indispensable.

The various modes of embalming were then described, all involving a process of steeping in natron for 70 days. The bodies of the poor were preserved by soaking in salt and hot bitumen, whence the name 'mummy.' Then followed a minute description of an Egyptian funeral, largely derived fiom the Papyrus of Ani, a finely illustrated 'Book of the Dead' a facsimile of which is in the National Museum.

The next paper was by Mr. A. L. Baldwin, of the Coast and Geodetic Survey, on 'The Measurement of Nine Primary Bases in 1900.' The bases referred to are those required to control the triangulation which is now being carried both northward and southward from the great transcontinental belt of triangulation in latitude 39°, and will eventually give an arc of the ninety-eighth meridian twenty-three degrees long in the United States. On this triangulation it was decided to measure the bases with considerable rapidity while keeping the accuracy fully up to the requirements of the triangulation. Five sets of base apparatus, namely, the Eimbeck duplex bars and four tapes, were used on each base, about one-fifth of the measurement being made with each. Each set of apparatus was standardized under the field conditions at the first and last base, using the iced bar formerly employed on the Holton Base as the standard. The paper was a statement of the methods of measurements and of some of the results obtained in the field, and closed with a good series of twenty-six lantern slides showing the different forms of apparatus in actual use in the field. The greatest difference between measures of the same base was 20 mm. to the kilometer. The nine bases were measured by a party of ten officers and men in but little more than six months.

CHARLES K. WEAD,
Secretary.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 339th meeting was held on Saturday evening, April 20th. Mr. O. F. Cook read a paper on 'The Shading of Coffee,' in which he advanced the belief that there is no basis in reason or observed fact for the common idea that shade is a general necessity for the coffee plant. It was shown that the beneficial effects connected with shade arise only from the protection afforded against drought, erosion and winds, and that in regions not affected by injurious climatic extremes the planting of shade trees is justified from the cultural standpoint only by the increased fertility imparted to the soil by means of the nitrogen-fixing root tubercles of leguminous species. This being the case, it was thought that leguminous fertilizing might be effected by shrubs and herbs yielding edible or otherwise useful fruits and requiring no more space or care than those yielding no direct returns.

Mr. Charles L. Pollard presented a paper entitled 'Some Strange Methods of Plant Naming,' giving a brief review of the various classes of incorrect generic and specific names, and commenting on the practices that have been followed in each case. He discussed particularly the so-called barbaric names of Adanson and Necker; those falsely constructed from classical sources, and those whose meanings are at variance with actual facts. The speaker also discussed the modern tendency to carelessness in the publication of scientific names, and recommended that botanists give united support to some movement in favor of greater exactness in nomenclature.

Dr. Theodore Gill made some remarks 'On the Mode of Progression and Habits of some

Dinosaurs,' contending that the supposed saltatorial habits of forms like *Hadrosaurus* and *Iguanodon* were physical impossibilities. Besides noting that the force of gravity would prevent so much action in such ponderous animals, the speaker also mentioned structural characters incompatible with it—notably the absence of the calcaneum.

WILFRED H. OSGOOD,
Secretary.

TORREY BOTANICAL CLUB.

AT the meeting of the Club on February 27, 1901, the scientific program was introduced by Dr. Britton with a paper 'On some *Senecios* of the Eastern United States.' The critical study of this genus dates from 1893, when Dr. Rusby collected in the Green Mountains a peculiar plant, described but not published in the middle of the century by Oakes and named by him *Senecio Robbinsii.* Dr. Rusby described this plant in the *Bulletin* in 1893.

While working up the genus for the Illustrated Flora 1895–6, Professor Britton found that *Senecio aureus* of Gray's Manual included the six following species: *Senecio obovatus*, *S. discoideus*, *S. Balsomitae*, *S. Smallii*, *S. compactus*, *S. Robbinsii;* besides *S. aureus* with two varieties. Professor Britton showed specimens of the species discussed: 1st, *S. aureus*, common and known by its large cordate basal leaves, growing in wet meadows; 2d, var. *gracilis*, with smaller cordate leaves, considered by Professor Greene a distinct species. Professor Britton had on one occasion observed intermediate forms and thought the distinction not clearly established. Both forms are growing in the Composite beds in the Garden. 3d, var. *pauciflorus*, smaller in every way than *S. aureus*, found in Newfoundland and Labrador; 4th, *S. Robbinsii*, smooth, with thin and jagged leaves, belonging to New England and the Adirondacks; 5th, *S. Smallii*, with long basal leaves and large corymbs of small heads. This occurs in the south, and is reported as far north as Pennsylvania. 6th, *S. obovatus*, with obovate leaves, including two subspecies, the first *elongatus* from the Delaware valley, with the lower portion of the leaves elongated, and smaller heads almost devoid of rays; the second, *rotundus*, from Tennessee and Missouri, which may be a distinct species. *S. discoideus* and *S. compactus*, are western species, separated by Dr. Rydberg.

Professor Britton quoted from a recently published study of *Senecio* by Professor Greenman, who distinguishes two additional varieties of *S. balsamitæ*, *pauperculus* and *prælongus.* Professor Britton said that there was much need of further material and observations in the field of all these forms.

Specimens of the *tomentosa* group of *Senecio* were then shown: *S. tomentosus* of Michaux, common along the Atlantic seaboard as far north as New Jersey; *S. antennarifolius*, found by Dr. Allen and Professor Britton at the White Sulphur Springs in West Virginia. This species is established in the Garden and flowers early.

A peculiar and undescribed species was exhibited collected by Professor Earle in Henry County, Alabama, resembling the *tomentosa* group in general characters, but having no tomentum. This differs from all other species in having the teeth tipped with round glands.

Dr. Britton expressed the hope that field notes on this genus would be made during the coming season.

The second paper, also by Dr. Britton, was on *Eupatorium*, and illustrated the three Linnæan species, *E. purpureum*, *E. maculatum*, and *E. trifoliatum*; the first two were collected at Copake Iron Works last summer on a field excursion of the Club. Of these, *E. purpureum*, with thin almost glabrous leaves with sharp teeth, grows in woodland and copses; and *E. maculatum* has leaves thick and rugose, with prominent veins broader and more ovate, and not as sharply serrate as the last; stem rough and spotted; grows in open meadows.

E. trifoliatum has been found in the South, as far north as Pennsylvania; it was named by Elliott *E. ternatum.*

The essential distinction of this species is the crenate leaves; the stem is smooth, the leaves narrower and inflorescence often larger than *E. purpureum.*

Dr. MacDougal showed an opened spathe of skunk cabbage found in the Garden, which was greeted as the first authentic sign of spring.

He exhibited an experiment on the force exerted in the swelling of seeds; a strong iron pipe was filled with peas and water, and a test tube inserted in the top. In 24 hours from the time the peas were put in, a pressure was registered of eight atmospheres, or 120 pounds to the square inch, the highest pressure hitherto recorded by this means.

Dr. MacDougal also discussed malformations in *Arisaema*, and showed specimens of *A. triphyllum* with the spathe double or forked, with the spadix divided and flattened or proliferous, and with two leaves from the same petiole. Also *A. dracontium* with the tapering end of the spathe divided into double hood-like forms. He called attention to the fact that early specimens may be infested with a fungous growth which causes the hood to stand erect.

Edward S. Burgess,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE KEELER MEMORIAL.

Professor Keeler's sad and sudden death last August came as a great and unexpected shock to his many friends and admirers. Of his work and life it is unnecessary to speak here; it has been sympathetically and ably described by Campbell, by Hale, by Brashear, by Perrine and others. The whole scientific world has united to mourn his loss, both as a colleague and as a friend. But nowhere has his death been more keenly felt than among his many friends and associates whom he formed while connected with the Allegheny Observatory. It was here that he began his scientific career as assistant to Professor Langley, and it was here, as Langley's successor, that he subsequently accomplished much of the work that has rendered his name famous.

It seems therefore particularly fitting that the new Allegheny Observatory, the first plans for which were drawn by Keeler, should contain a memorial to his memory. When the news of his death was received we arranged to have his name placed on the frieze of the new building among the names of other great American astronomers of the past. But some more special tribute is needed to mark our appreciation of his high attainments as a scholar, of his distinguished services not only to our own observatory, but to the whole scientific world, and last but by no means least to his noble character as a man.

Keeler's last great work, the work upon which he was still engaged when death so suddenly cut him down in the prime of life, was being carried on with the Crossley reflecting telescope, an instrument which for the first time under his able management was being made to demonstrate its possibilities. It is proposed, therefore, to erect the 30-inch reflecting telescope of the new Allegheny Observatory as a peculiarly fitting memorial to his memory; one which he himself would prefer to any monument or statue. The suggestion has met with much favor among his many friends, and a fund is now being raised to carry it into effect.

We desire to make this memorial a general rather than a local tribute to Professor Keeler. A number of voluntary subscriptions have already been promised, and many of his scientific friends and colleagues from other institutions have expressed a desire to contribute. We feel sure that there are many others that only await an opportunity or an invitation to join the movement, and I have therefore written this notice to bring the subject to their attention. Those who wish to subscribe to the fund will kindly send their names and the amount of their subscription to Mr. John A. Brashear, chairman of the Observatory committee, or to the writer. All contributions will be acknowledged from time to time in Science. If the fund raised exceeds in amount the estimated cost of the memorial telescope, which is $10,000,* the balance will be used either to found a general fellowship for the study of astrophysics, 'the Keeler Fellowship,' or for the award of a 'Keeler Medal' for work in the same field, as the majority of the contributors may decide; the award in either case to be made by the Astronomical and Astrophysical Society of America or some other scientific body equally representative of general interests.

We hope all scientific men will join us in this effort to do honor to the name of one who did so much for the advancement of knowledge in

* It is expected that at least this amount will be subscribed here in Pittsburg and Allegheny alone.

his chosen field of work, who was so broadly sympathetic in his views, and who endeared himself to so many by his personal character and attainments.

F. L. O. WADSWORTH.

ALLEGHENY OBSERVATORY,
May 1, 1901.

THE LARYNX AS AN INSTRUMENT OF MUSIC.

I SEE in the last number (April) of the *American Journal of Science* an excellent paper by Professor Scripture on the 'Nature of Vowels.' After a graphic analysis of these sounds, he criticizes with much acuteness the views of other writers. Of this I have nothing to say, except that I have been greatly interested. But in the last paragraph he concludes that the so-called vocal cords cannot vibrate in the manner of strings nor of tongues of reed-pipes, but must vibrate *compressively* in the manner of *elastic cushions*.

Now I write this to say that somewhat similar views have been expressed by me in my class lectures on comparative physiology for 25 years, although not published until last year in my book on 'Comparative Physiology and Morphology of Animals.'

On p. 210 of that work, speaking of the *larynx as a musical instrument*, after showing that it cannot be likened to a stringed instrument nor to a reed-pipe, I say: "It is strange that no one has thought to liken it to an ordinary *horn*—a stage horn, or better, a *French-horn*. In this instrument the sound is modulated exactly as in the larynx, viz., by the *tension* and the *pressing together* of the *lips of the performer*. The edges of the *rima glottidis* ought to be called *the vocal lips*—as indeed they are, and not *the vocal cords*—which they are not in any sense. The analogy between the two instruments is perfect. The performer on the horn presses his lips together tighter, makes them tenser and the opening between them smaller, in proportion as he desires a higher note. He then drives the air between the tense lips so as to set their edges in vibration. This vibration, by alternate partial closing and opening of the aperture, gives rise to *successive jets or pulses of the out driven air*, and this in its turn gives corresponding pulses to the air in the sounding cavity of the horn. Precisely the same, as we have seen, takes place in the larynx. The only wonder is that so small an instrument as the larynx and the mouth-cavity should be capable of such marvelous effects."

It is true I do not say anything about '*compressive vibrations*,' but I think there can be no doubt that the nature of the vibrations in the two cases is identical.'

JOSEPH LE CONTE.

BERKELEY CAL., April 24, 1901.

THE PHOTOGRAPHY OF FOSSILS.

TO THE EDITOR OF SCIENCE: In the current issue of SCIENCE (May 3, 1901), p. 710, report is given of a paper read before the New York Academy of Science by Mr. Gilbert van Ingen, on 'A method of facilitating Photography of Fossils.'

It may be of interest to your readers to know that a patent covering the process there described was issued in December 1899, and a company, the 'Scientific Photograph Company,' under the business management of Roger H. Williams (Address 28 East 28th St., New York) has been formed to execute orders for the preparation of illustrations by this patented process. The results obtained are successful in reproducing the most delicate details of the form of opaque objects of all kinds in which accuracy is demanded. The process eliminates both the interpretation of the artist and the distorting effects of color and uneven reflection of natural surfaces, and is proving of great value as a means of reproducing, in publications, the exact form of fossils and other objects.

HENRY S. WILLIAMS.

SHORTER ARTICLES.

VARIATION IN LIGHT OF EROS.

THE range of variation in the light of Eros, which has been diminishing during the spring, has now become zero. In February, 1901, it was found by European astronomers to amount to 2.0 magn. Observations by Professor O. C. Wendell, with the Harvard Equatorial, showed that the range on March 12, 1901, was 1.13

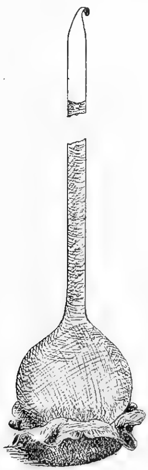
magn.; on April 12 it was 0.40 magn., and on May 6 and 7 it was imperceptible and apparently less than 0.1 magn.

EDWARD C. PICKERING.

HARVARD COLLEGE OBSERVATORY, May 8.

A SIMPLE OSMOMETER.

THE end of a thistle tube is drawn out, broken off and closed temporarily with wax. The bulb is then filled with molasses and a piece of pig's bladder,* is securely but loosely tied over the



mouth. The wax is removed from the end of the stem and the end well fused. Two thicknesses of strong linen are tightly drawn and securely tied over the membrane to take the strain. The bulb is then placed in water, when in a few minutes the column of liquid becomes higher and the air column compressed by the osmotic action through the membrane.

In two or three days the maximum pressure is obtained, then the length of the air column is taken. The air in the stem is allowed to expand to its normal condition by puncturing the membrane with a needle and the length of the air column measured; which length, divided by the length under compression, gives the pressure in atmospheres.

The greatest pressure I have yet obtained with an apparatus of this sort is the expansion of 1.5 cm. to 13.2 cm., showing a pressure of 8.8 atmospheres, or 668.8 cm. of mercury, or 129 pounds per square inch.

The highest pressure I find recorded for Pfeffer's cell is 436.8 cm. mercury.*

The air column after expanding will not be so long by six to eight per cent. as it was before compression, showing that some of the air has been absorbed by the liquid.

The accompanying figure will serve to show how the apparatus is arranged.

CURRENT NOTES ON PHYSIOGRAPHY.

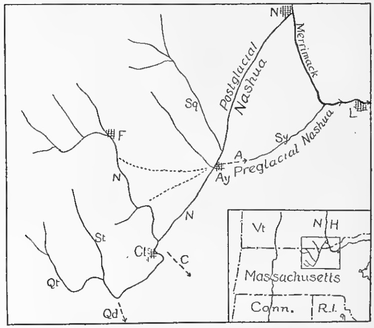
PHYSICAL GEOGRAPHY OF THE TEXAS REGION.

THE third folio of the Topographic Atlas of the United States is entitled 'Physical Geography of the Texas Region' by Hill. It may well serve as a type of many to follow. Twelve folio pages are given to text, chiefly concerned with an explanation of relief and drainage; then follow a sheet of nine climatic and other diagrams, four sheets holding 22 photographic views of typical landscapes, five sheets presenting 24 small topographic maps of typical reliefs and streams, and finally a folded map of Texas drawn under Hill's direction by Selden and Johnson on a scale of 25 miles to an inch with contours every 250 feet. The imperial area of the 'Texas region' is indicated by the statement that each of more than twenty physiographic subdivisions has an extent equal to that of an average State. Mountains, plateaus and plains, canyons, valleys and waste-floored basins (bolsones) are described in so great variety that selection for special remark is difficult. Descriptions are marked by a thorough-going adoption of explanatory methods, such as have always found ardent ad-

vocacy in Hill's writings. Terminology is largely flavored with words of Spanish origin, taken from the language that was once general and that is still familiar towards the Rio Grande. Plains are classified as constructional and destructional; the first being the result of accumulation, the second of denudation. Constructional plains are either sea-made or land-made; the latter including many examples of surfaces covered by the coarse or fine wash from higher ground. The destructional plains here found are usually 'stratum plains,' that is, surfaces of hard strata from which weaker overlying strata have been stripped; and of these three sub-classes are given, mesa plains, dip plains, and cut (or dissected) plains. Paleoplains is suggested as a name for buried destructional plains, but the word is objectionable etymologically; ancient plain may serve instead, as all the other classes of plains are indicated by adjectives. The descriptions of the Texan rivers show clearly enough that the conventional idea of a river as a constant current of water needs many modifications to fit it to regions of moderate rainfall and plentiful rock waste.

THE NASHUA VALLEY, MASS.

The 'Geological History of the Nashua Valley during the Tertiary and Quaternary periods' is discussed by Crosby (*Technology Quarterly*, Boston, XII., 1899, 288–324, 2 maps, 2 pl.). The lower lands of eastern Massachusetts are regarded as parts of a Tertiary peneplain, eroded beneath the uplifted Cretaceous peneplain of the central and western uplands of Massachusetts; the remnants of the latter form hills on the former. Previous to the Tertiary erosion, a coastal plain of Cretaceous sediments is supposed to have overlapped the southeastern part of the older peneplain and through this cover a number of east or southeast-flowing rivers were superposed on the greatly deformed and denuded underlying rocks. Traces of this system of drainage are found in the headwaters of certain rivers whose valleys now converge in a general southeasterly direction towards notches in the hills through which their united volume is thought to have once continued in about the same course, but from which it seems to have been in several cases diverted by headwater capture by small streams that grew along a belt of weak slates. The upper Nashua river is the best example of this kind, a number of its head-



Rough Diagram of Nashua River System, Mass. Cities: Ay., Ayer; Cl., Clinton; F., Fitchburg; L., Lowell; N., Nashua. Streams: N. N., Upper Nashua; Qt., Quinepoxet; Sq., Squannacook; St., Stillwater, Sy., Stony. Tertiary Water Gaps: A., Ayer; C., Clinton; Qd., Quinsigamond.

water branches having been gathered from other systems into a single trunk. During the progress of these captures and adjustments, broad, low-grade valleys were opened, their sub confluent floors constituting the Tertiary peneplain, above mentioned. A number of narrow gorges in these valley floors, now concealed by drift and discovered by borings in connection with the extensive works of the (Boston) Metropolitan Water Board, are explained as the result of a preglacial elevation; and as such they may come to be compared with the narrow young valleys so distinctly seen in the uplifted Tertiary peneplain of Pennsylvania, but not hitherto identified in central New England. During the retreat of the ice sheet, lakes were formed in front of it in the upper Nashua valley; their outlets were across notches among the hills, at whose level a number of deltas and sandplains are now found. Drift obstructions in the broad notch traversed by the preglacial Nashua trunk seem to have diverted its flow northeastward along its present lower course into the Merrimack.

It is to be hoped that fuller details, especially in

the form of maps, may in due time be presented regarding the glacial lakes above noted. As to the restoration and development of the Tertiary drainage systems, the problem is inherently difficult on account of the unproved inland extension of the Cretaceous coastal plain, of the complicated rock structure of the region, of the uncertain relation between river volume and valley size in the advanced stage reached by the Tertiary cycle of erosion before the glacial period, and of the large volume and irregular distribution of the drift. Additional examples of streams, explainable by the same theoretical process, would perhaps lead as far towards demonstration as the case allows.

W. M. DAVIS.

CURRENT NOTES ON METEOROLOGY.

MONTHLY WEATHER REVIEW.

THE *Monthly Weather Review* becomes more and more indispensable to teachers and students of meteorology with every succeeding number. Under the able editorship of Professor Cleveland Abbe, the *Review* is rapidly enlarging its scope and its sphere of usefulness. The number for December (issued in February) contains, among its special contributions, 'The Circulatory Movements of the Atmosphere,' a translation of portions of a paper by Professor V. Bjerknes, recently published in the *Meteorologische Zeitschrift*, and 'Line Integrals in the Atmosphere,' by Professor F. H. Bigelow. In the 'Notes by the Editor,' Professor Abbe takes up a great variety of topics. In 'Micro-Photographs of Snow Crystals,' the history of the study of snow crystals is briefly reviewed. Under 'Bombarding the Hail Clouds' the question as to the possibility of dispersing hail storms by means of cannonading is answered by Professor Abbe as follows: "The Editor would state that although statistics show that during the past year 15,000 shooting stations were established in Italy, and a very large number in southern France and Austria, yet there is no evidence whatever that the shooting done by these stations has had any effect whatever upon the hailstorms or the hail." A short paper on 'Oscillations of the Lakes and the Climate in Arid Regions' mentions the decreasing depth of Great Salt Lake, the notable diminution of the quantity of water in the streams and wells of Turkestan and Bokhara, and the shrinking of Lake Ngami, in South Africa, and points out that these observations do not indicate a permanent change in the conditions of the atmosphere, these lakes having gone through many similar dry periods before now. Other papers are 'The Commercial Importance of Storm and Weather Forecasts,' 'The Evolution of the Thermometer' (a review of Dr. H. C. Bolton's recent book); 'Correlation of Weather in Distant Localities,' and 'Lightning from Cloudless Skies.' A recent investigation of the 'Relations between Summer and Winter Temperatures,' by Dr. O. L. Fassig, of Baltimore, is found to show that neither warm nor cold summers have any more relation to the succeeding winter temperatures than have the normal summers, or, in general, that there is no regular alternation or period in atmospheric temperatures.

NEW CHARTS OF MEAN MONTHLY RAINFALL.

THE first charts showing the mean monthly rainfall for the world were constructed by Dr. A. J. Herbertson, and published in Bartholomew's new 'Atlas of Meteorology' (1891). Several charts of mean annual rainfall had previously been published, the first fairly complete one being that of Loomis (*Am. Journ. Sci.*, third series, Jan., 1882; revised edition, *Ibid.*, Jan., 1883). Seasonal rainfall charts have recently been constructed by Supan. Herbertson's monthly rainfall charts have now appeared in 'The Distribution of Rainfall over the Land' (*Roy. Geogr. Soc.*, London, 1901, 8vo, pp. 70), on a considerably larger scale than that adopted for them in the 'Atlas of Meteorology.' The discussion is also much more extended than in the 'Atlas.' This monograph will naturally not attract as much attention as it would have done had not the charts already appeared, but nevertheless it may be said that Herbertson's 'Distribution of Rainfall over the Land' is one of the most important meteorological publications of recent years.

NOTES.

ARCTOWSKI, the meteorologist of the *Belgica* expedition, contributes to *Ciel et Terre*

for March 16th a paper entitled 'A propos de la question du climat des temps glaciaires,' in which he states it as his belief that the problem of the climate of glacial periods will be solved through a careful study of the meteorological and other conditions of the Antarctic.

Mr. H. N. Dickson, lecturer in physical geography in the University of Oxford, contributes a paper on 'The Circulation of the Surface Waters of the North Atlantic Ocean' to the *Philosophical Transactions of the Royal Society of London*, Series A, Vol. 196, pp. 61–203. The plates, which are colored, show the monthly distribution of temperature and of salinity in the surface waters of the North Atlantic during the years 1896 and 1897.

'Cloud observations during 1896 and 1897 at Toronto' is the title of a recent publication of the Meteorological Service of the Dominion of Canada (4to, Toronto, 1901, pp. 27). These observations were begun September 21, 1896, and were made by means of theodolites. The full tables of observations are given, but there is no discussion of the results, there being only the briefest summary of average altitudes and velocities by months.

Mammoth Tank, in the eastern portion of San Diego Co., Cal., on the line of the Southern Pacific R. R., is one of the most interesting meteorological stations in the United States. 'The Climatology of Mammoth Tank' is the title of a brief article in the February number of *Climate and Crops: California Section.* The mean annual rainfall for 23 years is 1.81 inches. The maximum temperature recorded was 130°, on Aug. 17, 1878. The warmest month is July, with a mean temperature of 98.5°.

R. DeC. Ward.

FRANÇOIS QUESNAY.

The Smithsonian Institution has received a Livre d'Or, published in commemoration of M. François Quesnay, who died in December, 1774, at the age of eighty years, and was buried at his birthplace, Méré, Seine-et-Oise, France.

The monument and book were the project of the Société populaire, of which M. J. Allain-Le Canu was president and prime mover. The monument was determined upon at Méré during the Fête Scolaire held July 10, 1892, and was completed and inaugurated August 23, 1896. At both ceremonies there were large attendance and great enthusiasm. At the former, addresses were delivered by M. Quesnay de Beaurepaire, the great-grandson of him whom they honored, and at the latter by MM. Bourgeat, representing the Minister of Public Instruction and Beaux Arts, Frederick Passy, M. Bellan and M. Marcel Habert.

M. François Quesnay was an ignorant country boy. He did not learn to read until after he was eleven years old, when he became enamored of the science of medicine, in which he acquired such skill as that he was appointed physician to the King, Louis XV. He became the founder of the science of political economy in France, and finally one of the most learned men of his country and his age. His eminence in these branches of science was such that, two hundred years after he was born, his friends and the neighbors of his town, desiring to give him honor according to his renown, erected a monument in his memory in the town of his birth.

Alexander Quesnay, descendant of François, came to America and fought on her side during the War, of Independence. He remained here after the war, taking up his residence in Richmond, Va., where he was chosen and served as president of the Academy.

Thomas Wilson.

A SUMMARY OF WISCONSIN ARCHEOLOGY.

Members of the Wisconsin Society of Natural History are making systematic efforts to summarize the data of Wisconsin archeology and to preserve the archeological records, specimens and mounds of the State. A committee has been appointed for this purpose. It consists of C. D. Stanhope, H. Denison, W. J. Bennetts and Charles E. Brown. This committee has prepared a circular letter to be sent to every person in the State who is thought to be interested in the archeology of Wisconsin.

There are about three hundred collections of specimens from Wisconsin, varying in size from five hundred to five thousand objects, which

are known to be in different parts of the State. There are no headquarters for these collections, or for a typical series from them, nor is there any record covering the entire range of forms or number of geographical areas. Many specimens pass to foreign countries without a record or photographs being taken for the State. It is not the desire of the Wisconsin people to prevent the study of the antiquities of the State by outsiders or even their acquirement of specimens, but rather to secure records, drawings and other data for a central State collection to be available for study by all. Eventually State appropriations for a survey of the mounds are to be sought.

The Wisconsin Society of Natural History was founded by Increase Lapham and others, who began archeological work on a firm basis. It now proposes to establish a new grade of membership in the archeological section, for people living at a distance from Milwaukee. The regular membership fee is three dollars per year. The fee for the new grade will be one dollar. A meeting will be held at the Milwaukee Public Museum in May, to which all known students and collectors of Wisconsin archeology residing in the State will be invited. The object of this meeting will be to discuss ways and means for the study and preservation of Wisconsin antiquities.

It is hoped that students and collectors will be brought into closer relationship by the publication of a bulletin, which, it is expected, will be established as a result of this meeting. The foundation of an anthropological reference library, the lack of which is keenly felt, and a central place of record, where reports of explorations may be heard and discussed, is also expected by the committee as an outcome of the meeting.

The people interested in this movement may do lasting good by striving to preserve the prehistoric mounds by enclosing them in parks, by a close cooperation with the State University, by a broadening of the proposed archeological research into that of general ethnology, and, finally, by the foundation of a permanent department of anthropology in the University.

HARLAN I. SMITH.

SCIENTIFIC NOTES AND NEWS.

AT the annual meeting of the American Academy of Arts and Sciences, held on May 8th, it was unanimously voted to award the Rumford Medal to Professor Elihu Thomson 'for his inventions in electric welding and lighting.' The Academy has granted to Professor Theodore W. Richards, of Harvard University, the sum of $500 from the income of the Rumford Fund, in aid of a research upon the Thomson Joule effect.

PROFESSOR J. H. VAN'T HOFF, of the University of Berlin, will give a limited number of lectures on physical chemistry at the Kent Chemical Laboratory of the University of Chicago, beginning on June 19, 1901.

M. BERTHELOT, the eminent chemist, ex-Minister for Foreign Affairs, and permanent secretary of the Paris Academy of Sciences, who has been elected a member of the French Academy in succession to M. Bertrand, the mathematician, was officially welcomed to the Academy by Mr. Lemaître on May 2d.

M. ZEILLER has been elected a member of the botanical section of the Paris Academy of Sciences in the place of the late Adolphe Chatin. M. Zeiller received twenty-five votes, while twenty-two were cast for M. Renault. MM. Bureau Costantin and Mangin were also candidates.

THE following fifteen candidates have been recommended by the Council of the Royal Society for election to membership: Professor Alfred William Alcock, M.B., Mr. Frank Watson Dyson, M.A., Mr. Arthur John Evans, M.A., Professor John Walter Gregory, D.Sc., Captain Henry Bradwardine Jackson, R.N., Mr. Hector Munro Macdonald, M.A., Mr. James Mansergh, M.Inst.C.E., Professor Charles James Martin, M.B., Major Roland Ross, M.R.C.S., Professor William Schlich, Ph.D., C.I.E., Professor Arthur Smithells, B.Sc., Mr. Michael Rodgers Oldfield Thomas, F.Z.S., Mr. William Watson, B.Sc., Mr. William Cecil Dampier Whetham, M.A. and Mr. Arthur Smith Woodward, F.G.S.

AT the annual meeting of the American Academy of Arts and Sciences, held May 8th, the following elections took place: *Associate*

Fellows, T. C. Chamberlin, of Chicago, and John Fritz, of Bethlehem Pa.; *Foreign Honorary Fellows*, A. Celli, of Rome; A. Engler, of Berlin; F. von Richthofen, of Berlin, and G. Paris, of Paris.

AT a meeting held at Cambridge University on April 27th to make some acknowledgment of Professor G. D. Liveing's services to science it was resolved:

That as a mark of our personal regard for Professor Liveing and in recognition of his valuable services to science and to the University, town and county, a testimonial be presented to him, and that it consist of a portrait of him to be painted by an artist selected by a committee in conjunction with Professor Liveing; the destination of the portrait to be determined by the subscribers.

AT a meeting of the New York Academy of Sciences held on May 6th, Professor Franz von Leydig, of Würzburg, was elected an honorary member of the Academy. The Academy adopted also the following resolution, to be presented to Professor Leydig on the occasion of his eightieth birthday, on May 21st: "The New York Academy of Sciences extends to Professor Franz von Leydig many hearty congratulations on the occasion of his eightieth birthday. In offering to Professor Leydig an election to honorary membership, the members of this Academy desire to express their appreciation of his long-continued services to science, and of the profound and lasting influence that his memorable researches have exerted on the progress of zoology. With all best wishes they send him a cordial greeting from America."

MR. CHARLES HAWKSLEY has been elected President of the Institute of Civil Engineers, London. The council has made the following awards for papers read and discussed before the institution during the past session: A George Stephenson medal and a Telford premium to Mr. Harry E. Jones; Telford medals and premiums to Mr. G. A. Hobson and Mr. E. Wragge; a Watt medal and a Telford premium to Mr. Joseph Husband; Telford premiums to Mr. J. T. Ford, Mr. L. L. Buck, Mr. W. H. Stanger, Mr. B. Blount and Mr. W. J. Doak; Crampton prize to Mr. E. Sandeman.

KING EDWARD VII. has consented to become patron of the Royal Geographical Society and to continue the royal premium of two previous reigns for the promotion of geographical research, which takes the form of the two royal medals awarded annually. The Society itself has resolved to found a Victoria medal, to be awarded occasionally for research in scientific geography.

DR. REINHARD SÜRING has been appointed chief of division, and Dr. Johannes Edler aid, in the Meteorological Institute at Berlin.

DR. WILLIAM COLLINGSBRIDGE has been appointed medical officer of health for the City of London.

DR. ADOLPH MEYER will represent Clark University at the celebration of the 450th foundation of the University of Glasgow. Dr. Meyer is at present abroad, working in Germany and Switzerland.

PROFESSOR R. S. TARR, of Cornell University, will spend the summer vacation in Switzerland.

MR. T. NELSON DALE, geologist of the U. S. Geological Survey, who recently resigned his position as instructor in geology and botany at Williams College, will make his home, in September, at Pittsfield, Mass., and from that point continue his geological field work in eastern New York State and western Vermont.

DR. JUDSON SYKES BURY will deliver the Bradshaw lecture before the Royal College of Physicians in London, his subject being 'Prognosis in relation to disease of the nervous system.'

DR. IRVING COLLINS ROSSE, the author of various works on medicine and travel, died at Washington, on May 3d, at the age of forty-two years. Dr. Rosse was at one time professor of nervous and mental diseases in Georgetown University, and, in addition to his medical work, had taken part in several Arctic expeditions.

IT is announced that the Rev. James Chalmers, known for his anthropological observations in New Guinea, has been murdered by the natives.

DR. JOHN CAVAFY, formerly lecturer on physiology, demonstrator in histology and physician at St. George's Hospital, London,

has died at Brighton at the age of about sixty years. He was the author of numerous contributions to the medical journals.

MR. ANDREW CARNEGIE, who recently gave £6,500 to the British Institute of Mining Engineers for the encouragement of research, has now doubled this sum.

A TELEGRAM was received at the Harvard College Observatory on May 7th from Professor Kreutz at Kiel Observatory, stating that the south comet will appear in the Northern Hemisphere. It was observed at the Cape of Good Hope May $3^d.2115$ Greenwich Mean Time in R.A. $3^h\,40^m\,32^s.4$ and Dec. $-0°\,31'\,49''$ and was also observed May $4^d.2187$ Greenwich Mean Time in R.A. $3^h\,54^m\,29^s.2$ and Dec. $-0°\,18'\,27''$. The physical appearance is as follows: circular, less than $1'$ diameter, brighter than 3d magnitude, well-defined nucleus, tail longer than 2°.

THE Society for the Promotion of Engineering Education will hold its ninth annual meeting at Buffalo, beginning on June 29th.

A CABLEGRAM to the New York *Times* states that at a meeting of the Royal Society last week a plan was considered to enlarge the scope of the Society, so that it should embrace literature, and the other subjects included in the five academies of the Institute of France. It is said, however, that no action was taken.

WE learn from the *Northwestern Daily Mail* of April 22d (Barrow-in-Furness, Lancashire, England) that an urn of ancient workmanship has been discovered below the upper Boulder Clay, in the Isle of Walney, near Barrow. The urn lay ten feet below the surface and some forty feet above sea-level in coarse sand on a pan of sandstone beneath the clay. The excavation was for brickworks, the manager of which is confident that the rock had not previously been disturbed. The urn is eight inches in diameter, with a wall average one-fourth inch in thickness composed of at least four layers of a very fine paste of a brown tint and exceedingly hard; its outer surface is smooth and unornamented. This important find is being further investigated by Mr. Harper Gaythorpe of Barrow-in-Furness.

IT is stated in the *Times* that experiments were carried out in London on May 1st by a party of balloonists under the direction of Mr. Percival Spencer, with the object of testing the general direction of the atmospheric currents across London and of investigating the phenomena of sound in the higher reaches of the atmosphere. Four balloons ascended from the Crystal Palace, St. Anne's-grounds, Barnes, the Welsh Harp, at Hendon, and the West Ham Gas Works. The balloon from the Crystal Palace, which ascended at 4:04 p. m., reached Dorking at 5:55. The balloon which left West Ham at 4 p. m. descended at Headley, near Epsom. The greatest altitude attained was 5,500 ft. Snow was encountered above the height of a mile.

THE annual meeting of the members of the Royal Institution was held in London on May 1st, Sir James Crichton-Browne, the treasurer, being in the chair. The annual report of the committee of visitors, testifying to the continued prosperity and efficient management of the Institution, was read and adopted, as was also the report of the Davy-Faraday Research Laboratory. Forty-seven new members were elected last year, and 63 lectures with 19 evening discourses were delivered. The following were elected as officers for 1901–1902: President, the Duke of Northumberland; Treasurer Sir James Crichton-Browne; Secretary, Sir William Crookes; Managers, Sir Frederick Abel, Sir William de W. Abney, Sir James Blyth, Sir Frederick Bramwell, Dr. Thomas Buzzard, Viscount Gort, Dr. Donald Hood, Lord Kelvin, Sir Francis Laking, Mr. Hugh Leonard, Dr. Frank McClean, Mr. James Mansergh, Mr. George Matthey, Mr. W. H. Spottiswoode, and Lord Justice Stirling; visitors, Sir Andrew Noel Agnew, Dr. C. E. Beevor, Mr. W. H. Bennett, Dr. Francis Elgar, Mr. Joseph G. Gordon, Dr. J. Dundas Grant, Lord Greenock, Mr. Maures Horner, Mr. H. F. Makins, Sir Thomas Sanderson, Mr. W. S. Squire, Mr. Harold Swithinbank, Mr. J. J. Vezey, Mr. Roger W. Wallace and Mr. James Wimshurst.

AT the meeting of the Council of the Royal Geographical Society, on April 28th, the Royal medals and other awards were made as follows: The founders' medal to the Duke of

the Abruzzi. The Duke undertook, at his own expense, in 1897, an expedition to Mount St. Elias in northwest America, which he for the first time ascended to its summit, 18,060 feet above sea level (July 31, 1897). In 1898 he organized, again at his own expense, an expedition towards the North Pole by the Franz Josef Land route. The expedition made a successful voyage to Franz Josef Land, where winter quarters were established. During the winter the Duke organized a sledge expedition to the north, and, being incapacitated by frost-bite from leading it in person, entrusted the command to Captain Cagni, who succeeded in reaching the highest latitude yet attained by man—86° 33′ or 22′ beyond Nansen's furthest. By this journey over the frozen ocean Captain Cagni disproved the existence of the land shown on the maps to the north of Franz Josef Land, the northern parts of which were for the first time accurately surveyed. The scientific work of the expedition included determinations of positions by astronomical observations, observations of the state and distribution of the ice, investigation of the meteorological and tidal phenomena, the aurora borealis, gravity, and the geology of the lands visited. The patrons' medal was awarded to Dr. A. Donaldson Smith, who in 1894 organized at his own expense an expedition for purposes of exploration between Shebel river and Lake Rudolf, which had at that time never been reached from the north. Starting from Berbera in July, 1894, he pushed southeast to the headwaters of the Shebel, on which he threw much new light, made a wide circuit to the south, crossing the Jub, and making his way westward to Lakes Stefanie and Rudolf. He explored the lower course of the Omo, skirted the east shores of Lake Rudolf and, striking southeast through hitherto unknown districts to the Tana river, reached the east coast, having thus traversed the whole extent of the Somali and Galla countries from north to south. In 1898 he organized a new African expedition for the purpose of completing his former work. Leaving Berbera in August, 1888, he again reached the north end of Lake Rudolf, making *en route* considerable rectifications of the map; and, continuing his march westward, crossed for the first time the unknown tract of country lying between Lake Rudolf and the Upper Nile. Throughout his journey he executed a careful route survey, carrying a triangulation through from Somaliland to the vicinity of the Nile, and supporting this by frequent astronomical observations with theodolite and chronometers. The other awards were made to Mr. Louis Bernacchi and Captain Colbech for their aid in the Southern Cross Antarctic expedition, and to Captain Cagni for his journey to 86° 33′ N., on the Duke of the Abruzzi's expedition.

PROFESSOR WILLIAM RAMSAY has issued a report on the subject of the proposed institute for post-graduate education, which a wealthy Parsee, Mr. Tata, recently offered to endow. This report, according to the London *Times*, states that the institute should be placed with reference to the situation of raw products; its site should be where the climate admits of energetic work during most of the year; and it should, if possible, be near a coalfield or some source of electric power. Bangalore is selected as an ideal site; for the Mysore State is rich in minerals (iron, gold, magnesite, manganese ore, corundum, &c.), and sugar-cane and the poppy are cultivated there. The climate is temperate, the place is easily accessible, and the Cauvery Falls can provide enough power for many factories. The Mysore Government have offered land for the institute, and would probably aid the scheme with pecuniary support in recognition of the benefits which would accrue to the State from its operations. Professor Ramsay discusses the salaries, period of office, vacations, duties and restrictions of members of the staff, and the method of appointment to chairs. He suggests that mechanics should be engaged to make apparatus and to teach the students to use their hands. A mechanician in brass and iron and a glass-blower might be procured who could train native boys to become skilled workmen capable of constructing apparatus and machinery as the work of the institute increases. Students should be selected from Indian colleges and should be graduates in science, except those who come from engineering colleges. The students would

accumulate at the rate of 15 to 20 a year, and the total number in the institute would not exceed 60, an ample number for a staff of nine teachers in research work. In order that the scheme may be set on foot, Mr. Tata's generous benefaction needs a supplement of about £5,000 from the Government of India. As the Viceroy and several members of his Council have promised favorable consideration, it may be hoped that this modest grant will be forthcoming. "I can imagine few ways," says Professor Ramsay, "in which a contribution from the State is likely to have such substantial and far-reaching results on the prosperity of the whole people. For the establishment of industries would result not merely in giving employment to the small number of experts for whom this Institute is designed, but to a vast army of clerks, artisans, workman and also merchants, whose object would be the disposal of the manufactured articles produced from the raw materials existing in the country; whereas, by exporting the raw materials as such, the country is impoverished, for their extraction gives employment only to navvies and to the railway companies."

UNIVERSITY AND EDUCATIONAL NEWS.

THE Legislature of Minnesota has recently appropriated $25,000 for a new laboratory of agricultural chemistry, and $25,000 for the erection and equipment of a building for instruction in, and investigation of, veterinary science.

PHILLIPS ACADEMY, of Andover, Mass., has established a department of archeology with a fund of $150,000. A museum is about to be erected. Dr. Charles Peabody, of Harvard, is hon. director, and Mr. W. K. Moorehead is curator. There are about 40,000 specimens with which to begin study. They were collected during the past six years by Mr. Moorehead for the founder, whose name, at his own request, is withheld from publication.

MR. H. M. HANNA has given to Western Reserve University $12,000 to establish a research fellowship in its medical school in the departments of physiology and pathology.

THE alumni of Columbia University are making efforts to collect $400,000 for a hall for the college. It is hoped that the building may be erected by the time of the celebration of the hundred and fiftieth anniversary of the founding of the University in 1904.

EFFORTS are now being made to promote the better equipment of Queen's College, Belfast. It appears that the chair of pathology has been endowed and that a laboratory of physics and engineering has been promised by Mr. Pirrie. The sum of £5,000 has been given by Sir James Musgrave.

GROUND has been broken for the new Administration and Science Building of Colorado College. The sum of $160,000 has been secured for its erection and equipment, of which sum Dr. Pearsons, of Chicago, and Mr. W. S. Stratton have each contributed $50,000. The building will contain laboratories in all departments of science, lecture and recitation rooms, and a large natural history and geological museum.

THE Kent Laboratory of Chemistry at Yale University is now being enlarged in accordance with the bequest of $50,000 by A. E. Kent.

THE courts have decided that the Loomis laboratory must be relinquished by New York University. It would in this case go to the Cornell University Medical College, but we understand that the litigation will be continued.

AT the conference of the Presidents of the State Universities held at the University of Illinois, on May 1st, 2d and 3d, the following subjects were brought up for discussion:

1. What can be done to stimulate publication among university teachers and graduate students without over-stimulating it?

2. Is a uniformity of system in keeping the records and making the reports of State universities desirable and practicable?

3. How does one get rid of a professor who is industrious and attentive to his duties, who has good sense, whose influence upon students is good, but who by lack of ability and training is paralyzing the instruction of his department?

4. Should entrance requirements for colleges of agriculture be lower than for other colleges? What technical courses might be offered in agriculture without entrance conditions?

5. What, if anything, do the State universities owe to applicants for admission who are mature and anxious to increase their working efficiency, but who cannot meet entrance requirements?

6. What proportion of the Morrill Fund is usually devoted to agriculture, and what to mechanic arts, languages, etc., or branches not connected with agriculture?

7. Can anything be done to promote system in 'Agricultural Experimentation' under the Hatch Act?

8. What is to be said concerning physical training departments and athletic matters?

9. To what extent should university authorities permit class rushes and scrimmages?

10. What is the wise policy touching university inspection of high schools?

11. Should our universities maintain summer schools? Or, are four regular terms in the year advisable?

12. What ought our universities to do concerning the professional training of teachers?

13. Is a uniform standard for 'units' or 'points' in entrance requirements practicable?

14. What ought the State universities to claim in reference to the right of their graduates to teach in the common schools without examination by local commissioners?

15. How can other educational interests secure such national cooperation and pecuniary support as are accorded to the agricultural interests?

The Yale *Alumni Weekly* compares the changes in the election for senior studies next year with those of the class of 1886, when the elective system began. It appears that ancient languages fall from 34.8 per cent. to 23.9 per cent.; European languages rise from 10 per cent. to 14.7 per cent.; English from 9.2 per cent. to 14.7 per cent.; mathematics fall from 18.8 per cent. to 10 per cent.; natural sciences rise from 7.4 per cent. to 8.4 per cent.; philosophy falls from 9.1 per cent. to 5.6 per cent.; history rises from 7.2 per cent. to 10.1 per cent., and social sciences rise from 3.5 per cent. to 12.2 per cent.

The Council of the New York University has accepted the resignations of the entire faculty of the School of Pedagogy, consisting of six members, including the Dean. A special committee which recommended this action was authorized to reorganize the faculty.

It is expected that two new professorships will be established at the University of Toronto, one in geology and paleontology, and the other in mineralogy.

Dr. Franklin Carter has resigned the presidency of Williams College after twenty years of service.

At Columbia University Henry E. Crampton, Ph.D., has been made adjunct professor of zoology at Barnard College, and Mr. W. E. Kellicott assistant in this science. Mr. William Findlay has been made tutor in mathematics and Miss Julia L. Collis assistant in physics. In other departments of the University the following promotions and appointments have been made: George H. Ling, tutor in mathematics; Charles S. Forbes, assistant in mathematics; Alexis P. Anderson, curator of the herbarium; H. W. Shimer, assistant in paleontology; George I. Finlay, assistant in geology; George Canning Hubbard, assistant in analytical chemistry and assaying; Myron S. Falk, C.E., tutor in civil engineering; Adolph Black, instructor in civil engineering; Joseph C. Pfister, instructor in mechanics; A. L. J. Iveneau, tutor in metallurgy; Gilbert Tolman, assistant in physics; Holmes C. Jackson, assistant in physiological chemistry.

William J. Moenkhaus, graduate student at the University of Chicago, has been appointed assistant professor of zoology at the University of Indiana.

C. J. France, who expects to take the Ph.D. degree at Clark University, has been given charge of the biological work in the Jacob Tome Institute.

Thomas Hudson Beare, professor of mechanical engineering at University College, London, has been appointed to the chair of engineering in the University of Edinburgh, in succession to the late Professor Armstrong.

J. J. Sudborough, D.Sc., senior lecturer and demonstrator in chemistry at Nottingham University College, has been appointed professor of chemistry, at Aberystwith, in place of Dr. Lloyd Snape, now Secretary for Education for the County of Lancaster.

Dr. R. Spitaler, docent and assistant in astronomy in the German University at Prague, has been promoted to an associate professorship.

H. A. Rowland

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, MAY 24, 1901.

CONTENTS:

Professor Rowland, 1848–1901 (with plate): PRESIDENT DANIEL C. GILMAN 801

An Outline of the Progress in Chemistry in the Nineteenth Century: PROFESSOR EDWARD H. KEISER 803

Campanus: C. S. PIERCE 809

*PROFESSOR ROWLAND, 1848–1901.**

A GREAT man has fallen in the ranks—great in talents, great in achievements, great in renown. Not now need we recall the incidents of his life, nor estimate the characteristics of his impressive personality, nor enumerate his contributions to physical science. We are assembled in this academic hall as his friends, his pupils, his colleagues, about to follow his deserted body to the church, and there in silence to give thanks for such an example, or to utter, with his kindred, words of faith and hope, consecrated by the comfort they have given to the mourners of many climes and of many centuries. Before these last rites, we pause to think what sort of a man was this whom we so love and honor, whom we so lament, whose death, in one aspect, seems so premature; in another, crowned with the best that earth can give.

* An address before the officers and students of the Johns Hopkins University, assembled before the funeral, April 18, 1901.

Our friend was born with a powerful mind, and the older he grew the more powerful it appeared to those who knew him intimately and to those most capable of understanding the problems and the methods which engaged his thoughts. Others may have eyes as keen and fingers as facile, but his vision and his dexterity were controlled by a brain of extraordinary fineness, versatility and strength. Nobody could walk with him, hunt with him, sail with him, talk with him, work with him, without perceiving his firm grasp, his clear aim, his concentrated energy, his extraordinary powers. In early youth his mind was directed to the study of nature—not so much to plants and animals as to physical and chemical forces. This was the bent of his life. It is true that he was fond of music, classical music especially—Chopin's funeral march, for example—and he loved good works of art—the Madonnas of Raphael, for example.

Yet he cared but little for literature, having showed, in his early days, a boyish animosity toward Greek and Latin which he never wholly overcame. Aristotle was no authority to him. But the mysterious forces of the physical world—gravitation, sound, light, heat, electricity and magnetism—were his constant study. The principles of mechanics were to him of fundamental importance, and mathematics was subservient to all his investigations. In this broad field he was a reader, a student, an experimenter, an inventor, a discoverer, a philosopher. He knew how to ask a difficult and far-reaching question, and he knew how to seek the answer.

Extraneous considerations were excluded when he saw the point of an inquiry, and on that point he concentrated all his powers. For example, when he began the brilliant series of experiments in spectrography which made him peerless in this domain, he saw that the spectrum depended on the accuracy of the gratings, and the gratings on the dividing engine, and the dividing engine on the screw—so he began the study of light by devising and making a screw more exact than any screw that has ever been produced by the most accomplished makers of instruments of precision, and then he saw that photography must be improved before he could reveal to the eye of others the intricacy of the solar spectrum.

His intellectual apparatus was controlled by a powerful will. When he was determined upon a given course, no regard for consequences, no apprehension of perils or of difficulties, no dread of failure, proved a barrier. They heightened his zest. Fortunately his ends were noble and his proceedings wise, so that rarely, if ever, did failure disappoint him or weaken his self-confidence. He would have been a great soldier, a great explorer, a great lawyer.

But above his keen perceptions, his logic, his adaptation of means to ends, and his marvelous concentration, I must place another moral quality—one that appeals to every one of us, whether we understand his determination of the mechanical equivalent of heat, or the steps by which he arrived at the value of the ohm. This moral quality is the love of truth. Of course, he was true in all the ordinary relations of life. That is the beginning of truth, but not the end of it. He was also true in all his investigations, careful to eliminate errors, to avoid preconceptions, to shrink from hasty conclusions and inferences, to be critical of other investigations, to be accurate, exact, conscientious, to spare no pains, to shrink from no efforts, to conceal no difficulties, in order that the absolute facts might be established, so far as this can be done by limited humanity. To him science was another word for truth—not all the truth, but that amount of truth which the limited powers of man have discovered. He was a follower of Isaac New-

ton, picking up upon the seashore a few pebbles and discerning their lessons.

At the close of our first decennium, two speakers were brought forward to tell, respectively, what had been the aims of this University in providing for the study of science and letters. These speakers were Professor Gildersleeve and Professor Rowland. They had no preliminary conference, but each brought his discourse to a close by a return to the key-note—the key-note which had governed and should govern our personal behavior and the harmonies of our associated lives as members of the Johns Hopkins University.

Said the exponent of letters: "First and last, the scientific standard must be upheld for the university man, be he a student of letters, be he a physicist; and that standard is the absolute truth, the ultimate truth. 'Nothing imperfect is the measure of anything,' says the prince of idealists."

Said the man of science: "But for myself, I value in a scientific mind most of all that love of truth, that care in its pursuit, and that humility of mind which makes the possibility of error always present more than any other quality. This is the mind which has built up modern science to its present perfection, which has laid one stone upon the other with such care that it today offers to the world the most complete monument to human reason. This is the mind which is destined to govern the world in the future and to solve problems pertaining to politics and humanity as well as to inanimate nature.

"It is the only mind which appreciates the imperfections of the human reason and is thus careful to guard against them. It is the only mind that values the truth as it should be valued and ignores all personal feeling in its pursuit. And this is the mind the physical laboratory is built to cultivate."

These are words worthy to be recalled by the successive groups of students who come here for instruction and counsel as the years roll on. Let us sacredly cherish our inheritance.

In closing, let me call our departed brother, our dear colleague, our honored teacher, our ornament, our pride and our delight, by another nobler title. He was a servant of the Lord. If one who leads a life of purity, fidelity and integrity, and who consecrates, without self-seeking, his strength, his talents, his time, at home and at his laboratory, in health and in bodily infirmities, in youth and in maturity, to the interpretation of the laws by which the cosmos is governed, is a servant of the Lord,—then reverently and truly we may say of our departed friend he was a servant of the Lord, Maker of heaven and earth. Let me apply to him words of the Master, whom he was taught from childhood to revere. His 'eye was single' and 'his whole body was full of light.'

DANIEL C. GILMAN.

JOHNS HOPKINS UNIVERSITY.

---

*AN OUTLINE OF THE PROGRESS OF CHEMISTRY IN THE NINETEENTH CENTURY.**

CHEMISTRY is one of the youngest of the natural sciences. Its growth and development have taken place almost entirely in the past one hundred years. Nevertheless, it is well to remember that some of the foundation stones of the science were laid in the latter part of the eighteenth century. There was no such thing as a science of chemistry in the time of the ancient Greeks and Romans. Nor during the middle ages, nor previous to the year 1750 can there be said to have been any systematized chemical knowledge.

In the middle of the eighteenth century the attempt was made to explain in a general way that most striking of all ordinary

* Address delivered before the Academy of Science at St. Louis, on March 18th.

chemical changes, namely, fire or combustion. It was noticed that there are two classes of bodies, those that will burn and those that will not. The former were assumed to contain the element of fire or phlogiston. In the process of burning the phlogiston was supposed to escape into the air; the ashes or products of combustion remained behind. The act of burning was looked upon as a decomposition. Combustible bodies were all supposed to be of a compound nature, consisting of phlogiston and the products of combustion. In the act of burning these two elements separated, the phlogiston going off into the air, the products of combustion remaining behind as the ashes.

This first theory of chemistry was replaced by a better one in the year 1785 by Lavoisier, the distinguished French chemist. Last summer a bronze statue of Lavoisier was unveiled in Paris. It bears a single inscription, namely, 'The founder of Modern Chemistry.' Lavoisier found that when bodies burned the products of combustion were heavier than the original substances. A few years previous to this, in 1774, Joseph Priestley, the English clergyman, had found that when the red calx of mercury is heated oxygen gas is obtained, and that substances burn very brilliantly in this gas. Lavoisier repeated the experiments of Priestley, saw, what the latter failed to see, that burning was the union of oxygen with the burning substance and that combustion was a chemical combination and not a decomposition. 'There is no such thing as phlogiston, the element of fire,' said Lavoisier; and from this time on all substances that could not be resolved into simpler substances weighing less than the original substances were called elements.

Thus began a new era for chemistry, a quantitative era, in the year 1785. From now on the balance became the chief instrument of chemical investigation. Such in brief was the condition of chemistry one hundred years ago. The ideas of Lavoisier had, at the opening of the last century, come to be very generally accepted, but very little was known beyond these. Oxygen was the chief element and the oxides the chief compounds or, as Berzelius said: 'Oxygen was the center point about which chemistry revolved.' The knowledge of the composition of other substances was very imperfect. It was not even known at that time that substances do have a fixed composition; indeed the fundamental laws of chemical action were still all undiscovered. Almost nothing was known of the composition of substances of vegetable or animal origin, that great and important class of bodies that we now know as organic substances. A century ago it was not known that alcohol contained oxygen; this fact was found out in the year 1809. There were no laws and principles, no generalizations; chemistry consisted of purely descriptive matter, and that was often very imperfect. In organic chemistry was largely mineralogy, organic chemistry was chiefly botany.

Limited as chemical knowledge was when the nineteenth century opened, there were, however, certain men at work, who had adopted the quantitative methods of Lavoisier, and who soon made important discoveries. First of all Proust, in 1801, announced that every chemical compound has a fixed and definite composition, that when substances unite chemically they do so in definite ratios by weight. This statement of Proust's was not allowed to go unchallenged. C. L. Berthollet maintained that compounds have a variable composition, and that if there are any that do appear to have a fixed composition it is an exception and not the rule. For eight years the controversy was carried on between these men. Proust finally came out victorious. More and more analyses of compounds were made,

until it was clearly established that every distinct substance has a fixed and unalterable composition. The second great law of combination was discovered in 1804 by John Dalton, and it is commonly called the law of multiple proportions. To explain these laws of combination, Dalton introduced the atomic theory into chemistry, and from now on the great problem was to determine the relative weights of the atoms. When the history of chemistry in the nineteenth century comes to be written, it will be largely the history of the atomic theory, and for more than sixty years the two great problems to which the most eminent men gave their attention were the determination of the atomic weights and of the arrangement of the atoms in compounds. It would be a long story to trace out step by step how these problems were solved. The men who did most in this direction were Berzelius, Dumas, Liebig, Gerhardt and Laurent, Cannizzaro and Kekulé. As a result of their work, it began to be generally recognized, about 1865, that these two problems had been satisfactorily solved, and from that time on there has been no question as to the reasoning employed in fixing upon a number to represent the atomic weight of an element, or to determine the way in which the atoms are linked together in a compound.

Side by side with this development of chemical theory has gone the discovery of new elements and compounds. Instead of the thirty elements or simple substances known at the beginning of the last century, we now have seventy-eight. Instead of a few scores of distinct compounds of definite composition, we now have thousands of these substances. To-day there are known 75,000 compounds of carbon alone. In the years 1859 and 1860 Bunsen and Kirchoff devised the spectroscope, and it has become, next to the balance, the most important instrument of chemical investigation. By means of it the elements rubidium, cesium, thallium, indium, gallium, scandium and helium have been discovered.

THE PERIODIC LAW.

Soon after the atomic weights had been determined satisfactorily, a very remarkable relationship was discovered by Lothar Meyer and Mendelejeff to exist between the atomic weights and the properties of the elements. It was found that when the elements were arranged in the order of increasing atomic weights, beginning with the lowest and going up regularly to the highest, there was a periodic variation in the properties of the elements. For example, it was noticed that the 8th element resembled the first, the 9th was analogous to the 2d, and so on. Mendelejeff expressed this fact in the following way: "The properties of the elements," he said, "are a periodic function of their atomic weights." By means of this law Mendelejeff was able to foretell the existence of new elements and to predict their chemical and physical properties. When the table of elements was first arranged it was incomplete, there were blank spaces. Mendelejeff predicted that elements would be found that would fill these spaces, and from the properties of the adjoining elements he foretold the properties of the unknown elements. In this way he predicted the properties of an element that would resemble boron, another that would be analogous to aluminum, and a third that would be closely related to silicon. These predictions have all been fulfilled. In 1879 Nilson discovered scandium and found that it had all of the properties of the unknown element that resembled boron, in 1875 Boisbaudran discovered gallium; it was the element resembling aluminum, and in 1885 Winkler discovered germanium; its properties were almost identical with those that had been predicted for the element resembling silicon.

NEW ELEMENTS FOUND IN AIR.

In the last few years it has been found that ordinary air contains some elements, the existence of which had not even been suspected. For nearly three-quarters of a century it was supposed that we knew all about the composition of the air, but in 1892 Lord Rayleigh found that a globe filled with atmospheric nitrogen weighed more than the same globe filled with nitrogen made from chemical compounds containing nitrogen, and this observation followed up led to the discovery of argon, an inert gas, present to the extent of about one per cent. in the air. Then efforts were made to find argon in mineral substances; certain minerals that were supposed to give off nitrogen on heating were heated in vacuous vessels and thus helium was discovered. Recently Professor Ramsey has found two other inert gases in air besides argon; he obtains them by the fractional evaporation of liquid air, and he has named them neon and kripton. Quite recently it has been claimed that the mineral pitch blende contains the elements radium, polonium and actinium, and that these elements emit rays that are capable of producing skiagraphic images on sensitive plates, and of discharging electrified bodies.

PROGRESS IN INDUSTRIAL CHEMISTRY.

Hand in hand with the development of scientific chemistry and the discovery of new compounds has gone the improvement of manufacturing processes and the methods of industrial chemistry. At the beginning of the last century potash was the chief alkali, and this was obtained from wood ashes. Leblanc invented a method of obtaining soda from salt, and for many years this was the only way of getting alkali on the large scale. Now this method has been almost entirely replaced by the Solvay or ammonia-soda process, and it is very probable that before many years this in turn will be replaced by the electrolytic process of obtaining alkali from salt solutions. There is a constant evolution of new methods in chemical industry, the older processes have to give way to more economic and perfect methods. For more than one hundred years, all the sulphuric acid that is used has been made in lead chambers, and one improvement after the other was added to this process until it was brought to a high state of perfection; but now, with the opening of the new century, the sulphuric acid manufacturers are pulling down their lead chambers. A new and better method of making the acid has been devised. Sulphur dioxide and air are led over finely divided platinum and the resulting sulphur trioxide is conducted into water. It has long been known that sulphuric acid can be made in this way on the small scale in the laboratory, but it is only recently that the principle has been adapted to the commercial preparation of the acid. Heretofore the difficulty has been that the contact substance, the finely divided platinum, soon lost its activity. Now it has been found that this can be overcome by carefully purifying the gases before they come in contact with the platinum, and that, by keeping the temperature of the interacting gases below the point of decomposition of the sulphur trioxide, the action can be carried on indefinitely and on the commercial scale. The resulting sulphur trioxide is led into water and sulphuric acid of any degree of concentration obtained.

Other important changes in industrial chemistry have been brought about by the application of electricity to the preparation of chemical elements and compounds. Places like Niagara Falls that have abundant water power for the production of electric currents are rapidly becoming the seats of important chemical industries. The electric current is at present used chiefly in two ways in inorganic chemistry. First

it is used for the production of very high temperatures in the electric furnace. In simple form the electric furnace consists of a box made of fire bricks in which the carbon poles of an electric arc light are placed. Under the influence of the high temperatures produced between the carbon pencils nearly all metal oxides are reduced by carbon. Aluminium oxide is reduced in this way at Niagara Falls, and aluminium bronze, an alloy of aluminium and copper, is made. Sand is reduced in the same way, and the element silicon unites with the excess of carbon and forms the compound carborundum, an exceedingly hard substance which is used so extensively as a substitute for emery. Artificial graphite and phosphorus are also made in the electric furnace and the carbides of a large number of metals have been prepared. Of these carbides calcium carbide has become of commercial importance, as it is used extensively for making acetylene.

The other way in which the electric current is utilized is for the electrolysis of liquids, either solutions of substances in water or fused substances. At Niagara metallic sodium is now made by the electrolysis of fused caustic soda. One of the uses of the metallic sodium is to prepare sodium peroxide, the new bleaching agent, for which purpose the metal is burnt in dry air. Metallic aluminium is obtained by the electrolysis of aluminium oxide in a fused bath of cryolite. Caustic soda and chlorine are made by the electrolysis of salt solutions, and potassium chlorate by the electrolysis of potassium chloride solution. The electric current is also used in refining certain metals, for which purpose sheets of the crude metal are suspended at one pole in a bath of the metal salt and the pure metal deposited at the other pole.

During the past century great progress has been made in the methods of extracting the metals from their ores. Not only has this been true of iron, but of all the useful metals. As an example, it is only necessary to call attention to the cyanide process of extracting gold and silver. Gold and silver ores which are so poor that it was unprofitable to work them in previous years are now successfully treated with a solution of potassium cyanide, which has the power, in the presence of air, of dissolving the noble metals. It is this method which has largely contributed to the increased production of gold in recent years. Side by side with this improvement of metallurgical processes has gone the utilization of by-products. Not only is blast-furnace slag used in making Portland cement, but other slags, such as those obtained in the basic steel process and which contain phosphoric acid, are used as fertilizers. The sulphur dioxide formed by roasting lead and zinc ores is no longer allowed to escape into the air, but is converted into sulphuric acid.

PROGRESS IN ORGANIC CHEMISTRY.

But undoubtedly the most rapid strides in the development of chemistry have been made in the past century in that department known as organic chemistry. One hundred years ago our knowledge of the compounds occurring in the organs of plants and animals was very meager indeed. A few organic substances had been isolated, but their composition was very imperfectly known, as the methods of analysis were very crude. Liebig in 1830 improved the method of analyzing these compounds and thus laid the foundation of organic chemistry.

A century ago it was generally believed that organic compounds could not possibly be made artificially by synthesis in the laboratory, as was the case with mineral compounds. It was thought that a peculiar vital force in some way intervened in their production in the organs of plants and

animals, and that we could never expect to prepare them in the laboratory. But this idea soon had to be abandoned, for in 1828 Wöhler succeeded in building up urea from simple inorganic substances, and thus the first synthesis of an organic substance was effected. This was soon followed by that of acetic acid by Kolbe, and then year after year an ever larger and larger number of substances was added to the list of synthetic compounds. It would take too long to enumerate all the compounds that have been made artificially in the laboratory. It is enough to say that the hydrocarbons of petroleum, common alcohol, wood alcohol, fusel oil, the ethers, the etheral and essential oils, the fatty acids, glycerine, grape sugar and fruit sugar, coloring matters and dye stuffs like indigo and turkey red, aromatic substances like oil of bitter almonds, vanilline and coumarine and many others, have been made.

One hundred years ago it was generally believed to be impossible for two substances of entirely different properties to have the same composition. When Liebig in 1823 found that Wöhler had analyzed silver cyanate and stated the percentage composition, he saw that it was identical with the percentage composition of silver fulminate as found by himself. He at once wrote to Wöhler and told him that he must have made a mistake. Silver cyanate and silver fulminate were very different substances, he said; they could not possibly have the same composition. Wöhler repeated his analyses and found that they were correct. Liebig again analyzed silver fulminate and found that his figures also were correct. Both substances had the same percentage composition. A few years after, Berzelius showed that racemic and tartaric acids have the same composition, but different properties, and from this time on substances of this kind have been called isomeric. This phenomenon of isomerism, so rare at one time, is now very common. We have, for example, 55 substances having the formula $C_9H_{10}O_3$, all having the same elements in the same proportions, or the same kind of atoms and the same number of atoms of each kind. To explain isomerism it was necessary to assume that in these different bodies the atoms are differently arranged or grouped. Thus there came into chemistry the idea of structure or constitution, and by this term is meant the way in which the atoms are united to form the smallest particles of compounds. By studying the methods of formation and of decomposition of compounds it has been found possible to draw conclusions as to which atoms are more closely associated with one another. In the year 1865 the methods of determining the constitution of substances had been brought to a high state of development as the result of the work of Professor Kekulé in Bonn. Kekulé proved experimentally that in a compound each atom is not united directly with all the other atoms, but that certain atoms act like links in a chain and hold different atoms together to form definite structures.

The immediate effect of this theory was that it led to a great deal of work, the object of which was to determine the way in which the atoms are linked in different substances. When once this structure had been determined, it was easy to see how the compound might be built up from simpler substances. The outcome was that hundreds of substances were made synthetically, and in the attempt to make artificially the valuable and useful substances, very often new ones were discovered that in turn were found to possess valuable properties. For instance, after determining the constitution of atropine, Ladenburg, in making it synthetically, succeeded in making several modified atropines, such as homoatropine, which also have valuable properties. Professor Fischer attempted to unravel the

structure of grape sugar and to make it synthetically; he succeeded in this, but, in addition, he has made 20 other sugars that had never been known before.

As work went on in organic chemistry and the methods of working with these substances were improved, and the means of distinguishing between them became more refined, it was found that there were even finer kinds of isomerism than had at first been observed. It is possible to have two or more substances of identical composition and of exactly the same chemical behavior, but differing from one another in only a very slight way. For example one compound will rotate the plane of polarized light a certain number of degrees to the right while the other will rotate the plane the same number of degrees, but to the left. In short there are right and left handed compounds. This physical isomerism, as it is called, can only be explained by assuming a different arrangement of the atoms in space. Since 1888 a great deal of work has been done in the development of the theories of space chemistry or stereochemistry. We are in a position now not only to determine how the atoms are linked to one another but also how they are actually grouped in space. Stereochemistry is the most attractive field of research in organic chemistry to-day. Prominent among the men who have contributed to this department of chemistry are Van't Hoff, Wislicenus, Baeyer and Emil Fischer.

PROGRESS IN PHYSICAL CHEMISTRY.

During the past fifteen years the borderland between chemistry and physics has been very successfully cultivated, and a new department of chemistry has resulted. This is the department known as physical chemistry, and it deals with such subjects as thermo- and electrochemistry, with chemical statics and chemical dynamics and with the laws of solution and electrolytic dissociation. A great deal of progress has been made in all these directions. It is especially the new theories of solution and of electrolytic dissociation that have most profoundly changed our ways of looking at chemical action. We now regard a substance in solution as in a condition analogous to the gaseous state. Like a gas, the dissolved substance exerts pressure, and this pressure, which is known as osmotic pressure, obeys the same laws that gas pressure does. One great practical benefit that has resulted from the laws of solution is that it is no longer necessary to convert a substance into a gas in order to find its molecular weight; it is only necessary to dissolve it in some solvent, and from the changes which it produces in the freezing point or boiling point or vapor tension of the solvent to calculate the molecular weight.

The theory of electrolytic dissociation has greatly modified our ways of interpreting the ordinary reactions of analytical chemistry. We now hold that in all dilute solutions of acids, bases and salts, in short the compounds of inorganic chemistry, we have no longer the unchanged substances, but their positive and negative ions. In the act of dissolving in water the acids, bases and salts are more or less completely split into their ions, and the chemical changes that take place in these solutions are reactions between these ions. A great many facts of analytical chemistry, of electrolysis and such empirical laws as the law of thermoneutrality of salt solutions and of the constant heat of neutralization of acids and bases, heretofore inexplicable, have now received a rational and natural explanation by means of this theory of electrolytic dissociation.

Edward H. Keiser.

CAMPANUS.

Many of the early editions of the 'Elements' of Euclid, among them the *editio prin-*

ceps of 1482, carried a commentary said to be by 'Campanus of Novara.'* That means that everything except the enunciations was by Campanus; for the early notion was that all the demonstrations were the work of editors. Of course that was entirely erroneous and, as far as the first book is concerned, a most monstrous error, since that book is one of the most deeply studied statements that ever was drawn up in any branch of thought.

The Latin text of Euclid which accompanied this commentary had been derived indirectly from an excellent Greek text, decidedly superior to the common traditional text of later times; though in certain details it was faulty. But there are many indications that the translation was not made directly from the Greek, but from the Arabic. There is said to be a 'controversy' as to whether the translation was due to Campanus or not. But as far as I can discover, the 'controversy' consists in this, that everybody who has made any independent inquiry into the matter, such as Tiraboschi and Charles Jourdain, says that the version is that of Adelard of Bath; while the German writers, none of whom have really examined the evidences, either roundly assert that it is by Campanus or decline to enter into what they call the 'controversy.'

The commentary of Campanus is very unequal. In some places, especially in the tenth book, it rises to a high level of mathematical reasoning; while in some other places it is beneath criticism. For the most part, it is very respectable.

Campanus himself has remained an obscure personage. He has usually gone by the name of Campanus, *tout court;* but now and then he has been called Johannes Campanus. It appears that Joannes de Lyneriis, who, about 1310, wrote an 'Abbrieviatio Instrumenti Campani,' so calls him; and there is other XIVth-century evidence to prove that that was his name (see Boncompagni, XVII., 783, 784). In regard to his age, a MS. work of Petrus Peregrinus, to which internal evidence assigns the date 1261, refers to the planetary tables of Campanus (Boncompagni, I., 5), while Roger Bacon is said to speak of him as still living. These facts agree with the assertion of Baldi (whose life of Campano, dated 1588, is given in Boncompagni, XIX., 591), and fully proved by Tiraboschi (Storia della Letturatura Italiana, Tomo IV., Libro II., capo ii., § 8), that he was chaplain of Pope Urban IV., who reigned from 1261 to 1264.

I think that I can fix the date of the commentary upon the 'Elements' within a year or so. In the collection of elementary mathematical works which have been brought together by George A. Plimpton, Esq., there is a manuscript of this commentary upon vellum, written in a very handsome, but stiff and slightly elongated, book-hand, which might have been written at any part of the last half of the XIIIth century, though I think it would be surprising to find that it was as early as 1250. Just below the colophon of this MS., where the owner of such a book frequently wrote his name, one can read in a careful cursive hand of, say, the third quarter of the XIIIth century, or thereabout, a pious sentence in the first person by 'Jacobus Dei gratia Patriarcha Jerusalemitorum.' Observe that one hardly uses the phrase 'Dei gratia' except in speaking of oneself.

It can, therefore, be asserted with considerable confidence that, soon after this MS. was written, it came into the possession of a person so describable. But that could only be Jacques Pantaleone, who, having

* The colophon of the first edition reads: Opus elementorum euclidis megarensis in geometriam artem. In id quoque campani perspicassimi commentationes finiunt. Erhardus ratdolt Augustensis impressor solertissimus venetijs impressit. Anno salutis MCCCCLXXXII Octavis Calendis Junii. Lector Vale. Euclid was always confounded with Euclides of Megara.

been only a short time before elevated to the dignity of Patriarch of Jerusalem, became on the 29th of August, 1261, Pope Urban IV., the known friend of Campanus. He would naturally receive one of the first copies. Indeed, there is evidence that it was hastily given to him ; for the geometrical figures are not drawn all the way through the MS., notwithstanding its being an exceptionally handsome MS., for such a work. It seems, then, that the book must have been published, say, within a year of August, 1260.

If this inference be admitted, we have in the commentary of Campanus, considering its respectable strength, occasionally its remarkable strength, additional evidence of the promising beginning of science which was made in the thirteenth century until all that sort of thing was swept away before the flood of scholasticism ; while in its lapses into utter absurdity, though they are but rare, we meet with another characteristic which is marked in Petrus Peregrinus, in Roger Bacon, and in other scientific students of that period.

C. S. PEIRCE.

P. S. I notice that Moritz Cantor (II., 100) will have it that Urban reigned until 1281. Considering what a difference it would have made for the history of Sicily, for our friend Roger Bacon, and for some famous works of literature, if he had, the slip is, perhaps, worth notice.

When I can have the privilege of examining the MS. again and of consulting a library, I think I can strengthen my proof of the date of the work.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

THE following is the list of those who have been elected members of the American Association for the Advancement of Science and have completed their membership from January 1 to April 30, 1901. The list includes the names of twenty-six former members and fellows, who have since January 1st been restored to the list by payment of arrearages for more than two years.

Adams, C. C., University of Chicago, Chicago, Ill.

Adams, Frederick C., Teacher of Science, Classical High School, Providence, R. I.

Alderson, Victor C., Dean of the Technical College, Armour Institute of Technology, Chicago, Ill.

Alexander, Chas. Anderson, M.E., 10 Vine St., Batavia, N. Y.

Alleman, Gellart, Ph.D., Instructor in Chemistry, Washington University, St. Louis, Mo.

Alpers, Wm. C., 45 West 31st St., New York City.

Ames, Oakes, Assistant Director of the Botanic Garden of Harvard University, North Easton, Mass.

Appleton, John Howard, Professor of Chemistry, Brown University, Providence, R. I.

Ashmead, Wm. H., Department of Insects, U. S. National Museum, Washington, D. C.

Baekeland, Leo, M.D., 'Snug Rock,' North Broadway, Yonkers, N. Y.

Baerecke, John F., Ph.D., M.D., Professor of Biology, Stetson University, DeLand, Fla.

Bagby, J. H. C., Dept. Physical Science, Hampden-Sidney College, Hampden-Sidney, Va.

Baker, James H., President of the University of Colorado, Boulder, Colo.

Ball, Elmer Darwin, Assistant Professor of Zoology, Agricultural College, Fort Collins, Colo.

Ball, Miss Helen Augusta, 43 Laurel St., Worcester, Mass.

Bancroft, Frank Watts, Ph.D., Instructor in Physiology, University of California, Berkeley, Cal.

Bancroft, Wilder Dwight, Instructor in Chemistry, Cornell University, Ithaca, N. Y.

Bardeen, Charles Russell, Anatomical Laboratory, Wolfe and Monument Sts., Baltimore, Md.

Barr, Charles Elisha, Professor of Biology, Albion College, Albion, Mich.

Bauder, Arthur Russell, Instructor in Physics, Boardman High School, New Haven, Conn.

Beach, Miss Alice M., 932 W. Illinois St., Urbana, Ill.

Beach, Charles Coffing, M.D., 54 Woodland St., Hartford, Conn.

Beede, Joshua William, Atchison County High School, Effingham, Kans.

Beers, M. H., 410 Broadway, New York City.

Bentley, Wray Annin, Instructor in Metallurgy, Columbia University, New York City.

Bergström, John Andrew, Ph.D., Associate Professor of Psychology and Pedagogy, Indiana University, Bloomington, Ind.

Berkey, Charles Peter, Ph.D., Instructor in Mineralogy, University of Minnesota, Minneapolis, Minn.
Berry, Edward W., News Building, Passaic, N. J.
Biggs, Charles, 13 Astor Place, New York City.
Billings, Miss E., 279 Madison Avenue, New York City.
Billings, Miss Laura, 279 Madison Avenue, New York City.
Bishop, L. B., M.D., 77 Whitney Avenue, New Haven, Conn.
Black, Newton Henry, Master of Science in Roxbury Latin School, Boston, Mass.
Blake, Joseph A., M.D., 601 Madison Avenue, New York City.
Blakeslee, Olin Safford, Wesleyan University, Middletown, Conn.
Blasdale, Walter Charles, Ph.D., Instructor in Chemistry, University of California, Berkeley, Cal.
Boas, Emil L., 37 Broadway, New York City.
Boas, Dr. Franz, Am. Mus. Nat. History, Central Park, New York City.
Bolton, Thaddeus L., Ph.D., Dept. Philosophy, University of Nebraska, Lincoln, Nebr.
Boon, John Daniel, Professor of Physics, Chemistry and Geology, Granbury College, Granbury, Texas.
Bouton, Charles Leonard, Instructor in Mathematics, Harvard University, Cambridge, Mass.
Bowlus, E. Lingan, Professor of Biology, Mt. Union College, Alliance, Ohio.
Brackett, C. F., Princeton University, N. J.
Bradley, Walter Parke, Ph.D., Professor of Chemistry, Wesleyan University, Middletown, Conn.
Brewer, Charles Edward, Professor of Chemistry, Wake Forest College, Wake Forest, N. C.
Brewster, George Richard, Newburgh, N. Y.
Brooks, Morgan, Professor of Electrical Engineering, University of Nebraska, Lincoln, Nebr.
Brown, Amos Peaslee, Ph.D., Assistant Professor of Geology and Mineralogy, University of Pennsylvania, Philadelphia, Pa.
Brown, Stewardson, Germantown, Pa.
Brown, W. L., 42 West 72d St., New York City.
Bruner, Henry Lane, Ph.D., Professor of Biology, Butler College, Indianapolis, Ind.
Bruner, Lawrence, Professor of Entomology, University of Nebraska, Lincoln, Nebr.
Buist, John Robinson, M.D., City Board of Health, Nashville, Tenn.
Bullard, Warren Gardner, Ph.D., Instructor in Mathematics, Syracuse University, Syracuse, N. Y.
Bunker, Henry A., M.D., 158 Sixth Avenue, Brooklyn, N. Y.
Burt, Edward Angus, Ph.D., Professor of Natural History, Middlebury College, Middlebury, Vt.
Butler, Frank Edward, A.M., Th.G., President of Grayson College, Whitewright, Texas.
Butterfield, Arthur Dexter, Assistant Professor of Mathematics, University of Vermont, Burlington, Vt.

Cain, William, Professor of Mathematics, University of North Carolina, Chapel Hill, N. C.
Calder, George, 105 East 22d St., New York City.
Campbell, Douglas H., Stanford University, Cal.
Campbell, William Wallace, Director of Lick Observatory, Mt. Hamilton, Cal.
Carey, E. P., Professor of Chemistry, Physics and Geology, University of the Pacific, College Park, Cal.
Carroll, James, M.D., U. S. A., Washington, D. C.
Carroll, James J., Waco, Texas.
Carter, Henry C., 475 West 143d St., New York City.
Caswell, W. H., M.D., 201 West 55th St., New York City.
Cathcart, Miss J. R., The Barnard, 71st St. and Central Park, New York City.
Cattell, H. W., M.D., 3709 Spruce St., Philadelphia, Pa.
Chamberlain, Charles Joseph, Dept. of Botany, University of Chicago, Chicago, Ill.
Chamberlain, W. E., M.D., 111 Water Street, New York City.
Chambers, Frank R., 569 Broadway, New York City.
Chandler, Elwyn Francis, Instructor in Mathematics, University of North Dakota, University P. O., N. Dak.
Channing, Walter, M.D., Brookline, Mass.
Cheesman, T. M., M.D., Garrison-on-Hudson, N. Y.
Chester, Wayland Morgan, Associate Professor of Biology, Colgate University, Hamilton, N. Y.
Child, Charles Manning, Instructor in Zoology, University of Chicago, Chicago, Ill.
Chisholm, Hugh J., 813 Fifth Avenue, New York City.
Chisolm, George E., 19 Liberty Street, New York City.
Chittenden, Russell H., Director of Sheffield Scientific School of Yale University, New Haven, Conn.
Church, E. D., Jr., 63 Wall Street, New York City.
Church, Royal Tyler, Turin, Lewis County, N. Y.
Clark, Edmund, 105 Beech St., Flushing, L. I., New York.
Clark, Gaylord Parsons, Professor of Physiology, Syracuse University, Syracuse, N. Y.
Clark, Herbert A., Professor of Physics and Chemistry, High School, Kansas City, Kansas.
Clark, Hubert Lyman, Ph.D., Professor of Biology, Olivet College, Olivet, Mich.

Clarke, James Frederick, M.D., Fairfield, Iowa.
Clarke, Samuel Fessenden, Williamstown, Mass.
Cockerell, T. D. A., Professor of Biology, Agricultural College, East Las Vegas, New Mexico.
Cockran, Hon. W. Bourke, 31 Nassau St., New York City.
Coffin, C. A., 44 Broad St., New York City.
Collett, Samuel Williamson, Professor of Science, High School, Xenia, Ohio.
Collier, Price, Tuxedo Park, N. Y.
Conklin, E. G., Professor of Biology, University of Pennsylvania, Philadelphia, Pa.
Coulter, John M., University of Chicago, Chicago, Ill.
Cook, James B., Randolph Building, Memphis, Tenn.
Corter, William Harrison, Professor of Mathematics, Stone Mountain, Ga.
Craig, Wallace, 624 Howes St., Ft. Collins, Colo.
Crane, James M., Board of Education, Newburgh, N. Y.
Cranford, J. P., Wakefield, New York City.
Crocker, Francis B., Professor of Electrical Engineering, Columbia University, New York City.
Cryer, Matthew H., M.D., 1420 Chestnut St., Philadelphia, Pa.
Curtis, Charles B., 9 East 54th St., New York City.
Cushing, John J., 1001 Union Trust Bldg., Cincinnati, Ohio.
Cushman, Allerton Seward, Ph.D., Instructor in Chemistry, Bryn Mawr College, Bryn Mawr, Pa.
Cushny, Arthur R., Professor of Materia Medica and Therapeutics, University of Michigan, Ann Arbor, Mich.
Cutler, Colman Ward, M.D., 36 East 33d St., New York City.
Cutter, W. D., College of Physicians and Surgeons, New York City.

Daniel, John, Professor of Physics, Vanderbilt University, Nashville, Tenn.
Davis, George S., Detroit, Mich.
Davis, Herman S., International Latitude Station, Gaithersburg, Md.
Davis, N. S., Jr., 291 Huron St., Chicago, Ill.
Dawson, Percy Millard, M.D., Johns Hopkins Medical School, Baltimore, Md.
Day, William Scofield, Tutor in Physics, Columbia University, New York City.
Delafond, E., Ingenieur Chimiste, San Juan, Porto Rico.
Dennis, David Worth, Professor of Biology, Earlham College, Richmond, Indiana.
Devereux, W. B., 99 John St., New York City.
Dexter, Franklin, M.D., Associate Professor of Anatomy, Harvard Medical School, Boston, Mass.
Dimock, Mrs. Henry F., 25 East 60th St., New York City.
Dodge, Chas. Richards, U. S. Department of Agriculture, Washington, D.C.
Dodman, Alfred C., Jr., 235 West 108th St., New York City.
Dowell, Philip, Ph.D., Professor of Natural Science, Muhlenberg College, Allentown, Pa.
Downs, Edgar Selah, Assistant in Physics, Yale University, New Haven, Conn.
Droppers, Garrett, President of the State University, Vermillion, S. Dak.
Duane, William, Ph.D., Professor of Physics, State University, Boulder, Colo.
DuBois, Wm. E. B., Professor of Economics and History, Atlanta University, Atlanta, Ga.
Duke, Frank Williamson, Professor of Mathematics, Hollins Institute, Hollins, Va.
Dunstan, A. St. C., Professor of Electrical Engineering, Polytechnic Institute, Auburn, Ala.
Duval, Edmund P. R., Austin, Texas.
Dwight, Thomas, M.D., Harvard Medical School, Boston, Mass.

Eckles, C. H., Instructor in Dairy Bacteriology, Iowa State College, Ames, Iowa.
Ehrenfeld, Frederick, Ph.D., Instructor in Geology, University of Pennsylvania, Philadelphia, Pa.
Eiesland, John, Ph.D., Professor of Mathematics, Thiel College, Greenville, Pa.
Elliott, George T., M.D., 36 E. 35th St., New York City.
Ellis, H. Bert, M.D., 243–246 Bradbury Block, Los Angeles, Cal.
Enders, Howard Edwin, Professor of Biology, Lebanon Valley College, Annville, Pa.

English, William Thompson, M.D., Professor of Physical Diagnosis, Western University of Pennsylvania, Pittsburg, Pa.
Eno, A. F., 32 Fifth Avenue, New York City.
Epper, Rev. Frowin, O.S.B., Mt. Angel, Oregon.
Esmond, Darwin W., Newburgh, N. Y.

Faile, Thomas H., 45 South St., New York City.
Falk, Gustav, 24 East 81st St., New York City.
Farrand, Livingston, Columbia University, New York City.
Faught, John B., Professor of Mathematics, Northern State Normal School, Marquette, Mich.
Fay, L. G., Naval Office, 20 Exchange Place, New York City.
Findlay, Merlin C., Professor of Biology, Park College, Parkville, Mo.
Fisher, Irving, Professor of Political Economy, Yale University, New Haven, Conn.

Fisher, Robert Jones, 614 F St., N. W., Washington, D. C.

Fisk, Herbert F., Principal of the Academy, Northwestern University, Evanston, Ill.

Fiske, Thomas S., Columbia University, New York City.

Fleming, Dudley D., 249 Washington St., Jersey City, N. J.

Fletcher, Andrew, 339 West 77th St., New York City.

Flint, Austin, M.D., LL.D., Professor of Physiology, Cornell University Medical College, New York City.

Foote, Warren M., Credit Lyonnais, Dept. d'Etranger, B'd. des Italiens, Paris, France.

Foster, Lafayette Lumpkin, President of the Agricultural and Mechanical College of Texas, College Station, Texas.

Foster, William, Newburgh, N. Y.

Fraenkel, Joseph, M.D., 46 East 75th St., New York City.

Frankland, Frederick W., 346 Broadway, New York City.

Freeborn, George C., M.D., 215 West 70th St., New York City.

Freedman, William Horatio, Professor of Electrical Engineering, University of Vermont, Burlington, Vt.

Freeman, Charles, Ph.D., Director of Clark Chemical Laboratory, Westminster College, New Wilmington, Pa.

Freer, Paul C., Ann Arbor, Mich.

Freley, Jasper Warren, Wells College, Aurora, N. Y.

Frost, William Dodge, Instructor in Bacteriology, University of Wisconsin, Madison, Wis.

Fuller, George W., 220 Broadway, New York City.

Fuller, Myron L., Assistant Geologist, U. S. Geological Survey, Washington, D. C.

Fulton, Weston Miller, Instructor in Meteorology, University of Tennessee, Knoxville, Tenn.

Gager, C. Stuart, Professor of Biologic Science, New York State Normal College, Albany, N. Y.

Garrett, Hon. John W., 11 South Street, Baltimore, Md.

Gates, Fanny Cook, Instructor in Physics, Woman's College, Baltimore, Maryland.

Geisler, Joseph F., New York Mercantile Exchange, New York City.

Genthe, Karl Wilhelm, Instructor in Zoology, University of Michigan, Ann Arbor, Mich.

Gifford, John Clayton, Assistant Professor of Forestry, New York State College of Forestry, Ithaca, N. Y.

Gillette, C. P., Professor of Zoology, Agricultural College, Fort Collins, Colo.

Gleason, W. Stanton, M.D., Newburgh, N. Y.

Glenn, L. C., Ph.D., Professor of Geology, Vanderbilt University, Nashville, Tenn.

Gordon, Reginald, Columbia University, New York City.

Gouldy, Miss Jennie A., Newburgh, N. Y.

Graham, R. D., 35 Wall St., New York City.

Green, Horace, 80 E. Washington Sq., New York City.

Greene, Charles Wilson, Ph.D., Professor of Physiology, State University of Missouri, Columbia, Mo.

Gregory, Herbert E., Yale University, New Haven, Conn.

Griffith, C. J., Instructor in Dairying, Agricultural College, Fort Collins, Colo.

Griffith, Herbert Eugene, Professor of Chemistry, Knox College, Galesburg, Ill.

Griffith, John Howell, Professor of Mathematics and Civil Engineering, Clarkson School of Technology, Potsdam, N. Y.

Griffith, W. W., Instructor in Physics, State University, Columbia, Missouri.

Griswold, Clifford S., Head of Dept. of Physics, Groton School, Groton, Mass.

Grover, Frederick Orville, Professor of Botany, Oberlin College, Oberlin, Ohio.

Hague, James D., 18 Wall St., New York City.

Hall, Edwin Bradford, Wellsville, N. Y.

Halley, Robert Burns, Professor of Physics and Chemistry, Sam Houston Normal Institute, Huntsville, Texas.

Halstead, Charles H., Board of Park Commissioners, Newburgh, N. Y.

Hasslacher, Jacob, 100 William St., New York City.

Hard, Jas. M. B., Orizaba, Mexico.

Hastings, Edwin George, Assistant Bacteriologist, College of Agriculture, University of Wisconsin, Madison, Wis.

Hatcher, John Bell, Carnegie Museum, Pittsburg, Pa.

Havemeyer, John C., Yonkers, N. Y.

Havemeyer, W. F., 32 Nassau St., New York City.

Hazard, R. G., Peace Dale, R. I.

Heald, Fred. DeForest, Ph.D., Professor of Biology, Parsons College, Fairfield, Iowa.

Hedgcock, George Grant, University of Nebraska, Lincoln, Nebr.

Heller, Napoleon B., Professor of Mathematics and Astronomy, Fort Worth University, Fort Worth, Texas.

Henderson, William Edward, Ph.D., Ohio State University, Columbus, O.

Hering, Daniel Webster, Professor of Physics, New York University, University Heights, New York City.

Herrick, Glenn W., Professor of Biology, A. & M. College, Agricultural College P. O., Miss.

Herter, Christian A., M.D., 819 Madison Avenue, New York City.

Hewett, Edgar L., President New Mexico Normal University, East Las Vegas, N. M.

Hodge, Frederick Humbert, Professor of Mathematics, Bethel College, Russellville, Ky.

Holmes, Miss Mary S., 1331 N. Twelfth St., Philadelphia, Pa.

Hopkins, George B., 25 West 48th St., New York City.

Hornung, Christian, Professor of Mathematics and Astronomy, Heidelberg University, Tiffin, Ohio.

Howard, Orson, M.D., Professor of Biology, University of Utah, Salt Lake City, Utah.

Howard, S. Francis, Professor of Chemistry, Mass. Agric. College, Amherst, Mass.

Howe, Henry M., Columbia University, New York City

Howe, Herbert Alonzo, Director of the Chamberlin Observatory, University of Denver, University Park, Colo.

Howe, J. Morgan, M.D., 12 West 46th St., New York City.

Howell, John W., Ballantine Parkway, Newark, N. J.

Howell, William H., Ph.D., M.D., Professor of Physiology, Johns Hopkins University, Baltimore, Md.

Hower, Harry Sloan, Instructor in Physics, Case School of Applied Science, Cleveland, Ohio.

Howerth, Ira Woods, Instructor in Sociology, University of Chicago, Chicago, Ill.

Hoyt, Alfred M., 934 Fifth Avenue, New York City.

Huber, G. Carl, M.D., Junior Professor of Anatomy and Director of Histological Laboratory, University of Michigan, Ann Arbor, Michigan.

Hull, Gordon Ferrie, Professor of Physics, Dartmouth College, Hanover, N. H.

Hun, Henry, M.D., Professor of Diseases of the Nervous System, Albany Medical College, Albany, N. Y.

Hunter, Samuel John, Associate Professor of Entomology, University of Kansas, Lawrence, Kansas.

Hyde, Miss Edith E., U. S. National Museum, Washington, D.C.

Iorns, Martin J., Professor of Science, Fort Worth University, Fort Worth, Texas.

Jacobs, Henry Barton, M.D., Instructor in Medicine, Johns Hopkins Medical School, Baltimore, Md.

Jarvis, Samuel M., 1 West 72nd St., New York City.

Jesup, James R., 555 Fifth Avenue, New York City.

Johns, Carl, Instructor in Biology, Bethany College, Lindsborg, Kans.

Johnson, Frank Edgar, 747 Warburton Avenue, Yonkers, N. Y.

Johnstone, William Bard, Assistant in Physics, Columbia University, New York City.

Johonnott, Edwin Sheldon, Ph.D., Rose Polytechnic Institute, Terre Haute, Ind.

Jones, Charles C., M.D., Galveston, Texas.

Jones, Lynds, M.Sc., Instructor in Zoology, Oberlin College, Oberlin, Ohio.

Jones, Philip Mills, M.D., Mills Building, San Francisco, Cal.

Jones, W. R. T., 1 East 39th St., New York City.

Jordan, Edwin Oakes, Ph.D., University of Chicago, Chicago, Ill.

Kahl, Paul Hugo Isidor, Curator of Entomological Museum, State University, Lawrence, Kansas.

Kaufmann, Paul, M.D., Professor of Bacteriology, Pathology and Hygiene, State University, Columbia, Mo.

Kean, Mrs. Hamilton Fish, 25 East 37th St., New York City.

Kellogg, Vernon Lyman, Professor of Entomology, Stanford University, California.

Kennedy, Frank Lowell, Instructor in Lawrence Scientific School, Harvard University, Cambridge, Mass.

Kepner, Harry V., Instructor in Chemistry, Denver Manual Training High School, Denver, Colo.

Kern, Josiah Quincy, Ph.D., 507 6th St., N. W. Washington, D. C.

Keyser, Cassius Jackson, Instructor in Mathematics, Columbia University, New York City.

Kimball, Arthur Lalanne, Professor of Physics, Amherst College, Amherst, Mass.

King, Cyrus A., Ph.D., Instructor in Botany, University of Indiana, Bloomington, Ind.

Kinney, Charles Noyes, Professor of Chemistry, Drake University, Des Moines, Iowa.

Kirk, Elliott W., Teacher of Science in High School, Veedersburg, Ind.

Kirschmann, A., Ph.D., Toronto University, Toronto, Canada.

Krause, Otto H., Prospect Ave., Hackensack, N. J.

Landis, W. W., Dickinson College, Carlisle, Pa.

Landon, Francis C., Staatsburg-on-Hudson, N. Y.

Lane, Alfred C., State Geologist, Lansing, Mich.

Langsdorf, Alexander Suss, Instructor in Physics and Electrical Engineering, Washington University, St. Louis, Mo.

Lanneau, John Francis, Professor of Applied Mathematics and Astronomy, Wake Forest College, Wake Forest, N. C.

Lauman, George Nieman, Instructor in Horticulture, Cornell University, Ithaca, N. Y.

Lawrence, James W., Professor of Mechanical Engineering, Agricultural College, Fort Collins, Colo.

Leach, Miss Mary F., 74 Pitcher St., Detroit, Mich.

Leaming, Edward, 437 West 59th St., New York City.

Leathers, W. S., Professor of Biology, University of Mississippi, University P. O., Miss.

Lee, Waldemar, Passaic, N. J.

Leeds, Morris E., 3221 North 17th St., Philadelphia, Pa.

Le Grand, Leroy, M.D., Graham, Texas.

Le Rossignol, James Edward, Ph.D., Professor of Economics, University of Denver, University Park, Colo.

Leslie, Miss Augusta, Newburgh, N. Y.

Lichthardt, G., Jr., 18th and M Sts., Sacramento, Cal.

Lillie, Frank R., Assistant Professor of Zoology, University of Chicago, Chicago, Ill.

Ling, Charles Joseph, Instructor in Physics, Denver Manual Training High School, Denver, Colo.

Linn, Alvin Frank, Professor of Chemistry, Wittenberg College, Springfield, Ohio.

Little, C. A., Analyst at Lorain Steel Works, Elyria, Ohio.

Little, Henry P., Superintendent of Union Schools, Momence, Ill.

Long, William Henry, Jr., A.M., 2101 San Gabriel St., Austin, Texas.

Loomis, Frederick B., Ph.D., Assistant in Zoology, Amherst College, Amherst, Mass.

Lough, J. E., Professor of Psychology, State Normal School, Oshkosh, Wisconsin.

Lowber, Rev. James William, Ph.D., 113 East 18th St., Austin, Texas.

McAlpin, C. W., 11 East 90th St., New York City.

McKinney, Thomas Emory, Professor of Mathematics and Astronomy, Marietta College, Marietta, Ohio.

McLanahan, George William, 1601 21st St., N. W., Washington, D. C.

McMahon, D. J., M.D., 239 East 21st St., New York City.

McNulty, John J., 17 Lexington Avenue, New York City.

Mangan, Daniel C., M.D., 95 Park Avenue, Brooklyn, N. Y.

Mark, Edward Laurens, Director Zoological Laboratory, Harvard University, Cambridge, Mass.

Marston, Edwin S., 291 Clinton Ave., Brooklyn, N. Y.

Martin, W. R. H., 56 West 33d St., New York City.

Matas, Rudolph, M.D., Professor of Surgery, Tulane University, New Orleans, La.

Mercer, William Fairfield, Ph.D., Professor of Biology, Ohio University, Athens, Ohio.

Merrill, Payson, 111 Broadway, New York City.

Merrill, Joseph Francis, Ph.D., Professor of Physics and Electrical Engineering, University of Utah, Salt Lake City, Utah.

Metcalf, Maynard M., Professor of Zoology, The Woman's College, Baltimore, Md.

Metcalf, Wilmot V., Professor of Chemistry and Physics, Carleton College, Northfield, Minn.

Metcalfe, Captain Henry, 143 Liberty St., New York City.

Mezes, Sidney Edward, Professor of Philosophy, University of Texas, Austin, Texas.

Millar, John M., Escanaba, Mich.

Miller, Edmund H., Columbia University, New York City.

Miller, Ephraim, Professor of Mathematics and Astronomy, State University, Lawrence, Kansas.

Miller, George N., M.D., 811 Madison Ave., New York City.

Miller, John Craig, M.D., Professor of Natural Science, Lincoln University, Chester Co., Pa.

Miller, Miss Louise Klein, 631 Grand Ave., Dayton, Ohio.

Miller, Pleasant T., Temple, Bell County, Texas.

Mills, James, Ontario Agricultural College, Guelph, Ontario.

Mills, Samuel C., Newburgh, N. Y.

Mitchell, Edward, 44 Wall St., New York City.

Mitchell, Henry Bedinger, Tutor in Mathematics, Columbia University, New York City.

Mitchell, James, Newburgh, N. Y.

Mitchell, Roland G., 141 Water St., New York City.

Montgomery, Edmund, M.D., Hemstead, Texas.

Montgomery, James H., Meadville, Penna.

Moody, William Albion, Professor of Mathematics, Bowdoin College, Brunswick, Maine.

Moore, Ernest Carroll, Ph.D., Instructor in Philosophy, University of California, Berkeley, Cal.

Morgan, H. A., Professor of Zoology and Entomology, State University, Baton Rouge, La.

Morse, Albert P., Zoology, Wellesley, Mass.

Mottier, David M., Ph.D., Professor of Botany, University of Indiana, Bloomington, Ind.

Moulton, Forest Ray, Ph.D., Instructor in Celestial Mechanics, University of Chicago, Chicago, Ill.

Mt. Carmel Scientific Society, Mt. Carmel, Ill.

Nason, Frank L., West Haven, Conn.

Nelson, Aven, Professor of Biology, University of Wyoming, Laramie, Wyoming.

Nesmith, John W., 1100 Colfax Ave. E., Denver, Colo.

Notestein, F. M., Professor of Mathematics and Physics, Alma College, Alma, Mich.

Nylander, Olof O., Box 165, Caribou, Aroostook County, Maine.

Obrig, Adolph, 'The Dakota,' 1 West 72nd St., New York City.
Oestlund, Oscar W., Entomologist, State University, Minneapolis, Minn.
Oglevee, Christopher S., Instructor in Biology, Lincoln University, Lincoln, Ill.
Osborn, Frederick A., Professor of Physics, Olivet College, Olivet, Mich.
Osborn, Mrs. W. H., 32 Park Ave., New York City.
Osborne, Frank Russell, Professor of Physics, John B. Stetson University, DeLand, Fla.
Osborne, George Abbott, Professor of Mathematics, Mass. Inst. of Technology, Boston, Mass.
Osburn, Raymond Carroll, Professor of Zoology, Fargo College, Fargo, N. Dak.
Owen, Charles Lorin, Field Columbian Museum, Chicago, Ill.
Owen, Miss Juliette A., 306 North 9th St., St. Joseph, Mo.
Owen, Miss Mary Alicia, 306 North 9th St., St. Joseph, Mo.
Owens, William Gundy, Professor of Chemistry and Physics, Bucknell University, Lewisburg, Pa.

Paddock, Wendell, Professor of Botany and Horticulture, Agricultural College, Fort Collins, Colo.
Painter, Charles Fairbank, M.D., 372 Mulboro, St., Boston, Mass.
Pammel, L. H., Iowa Agricultural College, Ames, Ia.
Parker, George Howard, Assistant Professor of Zoology, Harvard University, Cambridge, Mass.
Parker, J. B., M.D., U. S. N., Washington, D. C.
Parmelee, H. P., 594 Cherry St., Grand Rapids, Mich.
Parsons, Mrs. Edwin, 326 West 90th St., New York City.
Paton, Stewart, M.D., 213 West Monument St., Baltimore, Md.
Peabody, George Foster, 28 Monroe Place, Brooklyn, N. Y.
Pell, Alfred, 15 East 35th St., New York City.
Piel, G., 148 Riverside Drive, New York City.

SCIENTIFIC BOOKS.

Topographic Surveying, Including Geographic, Exploratory and Military Mapping. By HERBERT M. WILSON, U. S. Geological Survey. New York, John Wiley & Sons. 1900. 205 Figures.

It is always a source of great satisfaction in picking up a book to know that the author by training and experience is qualified to speak with authority on the subject therein discussed. In the case of the book under review we have as its writer a graduate of one of our best schools of engineering, who afterwards served an apprenticeship under Mr. Henry Gannett, the master topographer, and then, after spending considerable time abroad, became one of the Division Chiefs of the Geological Survey.

Every feature of topographic work is taken up, treated exhaustively, and with the aid of illustrations and tables left in the shape deemed the most serviceable to the student. The descriptions of instruments and their adjustments are scattered through the book and the tables are inserted at the point where reference to them is first made. This is not the usual practice, and its practicability is a question of personal preference. Ordinarily we look in the back of the book for all tables and expect to find the first pages devoted to the description of instruments.

An important topic, seldom referred to, that is found in this treatise is the way in which to equip a party for field work, including the supplies needed, medicines that should be provided, and also suggestions as to how to look after the details of camp life. In this connection it might be suggested that space is given to some matters of trifling importance. However, the severest criticism that suggests itself is the frequent comparison of the work of the U. S. Coast and Geodetic Survey with that of the Geological Survey. This contrasting places the relative accuracy and cost in a misleading light and should not be so presented by an official of either organization. Then, too, the most expensive work of the Coast Survey has been to a great extent experimental, and many organizations have profited by the lessons thus learned—none more so than itself. As, for example, the work of Professor Woodward, which resulted in perfecting the tape-line base-measuring system whereby it was possible for a single party in the Coast Survey to measure nine bases in a single season. A wrong impression is given in comparing cost and accuracy, except when great emphasis is put on the fact that the cost increases rapidly with the accuracy—apparently out of reasonable proportion. If we say that one party can execute a primary triangulation at a cost of 90 cts. a square mile with a probable error of one-tenth of a foot for each side of this square while another charges $30 for a square mile and secures a probable error of three-hundredths of a foot, it looks as though we were paying more than thirty times as much to secure a probable error one-fourth as great. A still greater cause for comment is the statement that while both organizations demand the same degree of precision in precise leveling, one costs $10 a mile, while the other costs only $5.

It is far from the purpose of this review to question the accuracy of these statements, but the opinion is held that such comparisons create wrong impressions and react upon the author. It is believed that the author is in error when he says that in the topographic survey of the District of Columbia no system of bench marks was left in the course of the leveling, also that the St. Albans base was measured with the secondary apparatus, and that any form of tape-stretcher is more quickly manipulated than that used by the Coast Survey. The reason for referring to the matters just mentioned is that in the eyes of many they mar a book otherwise most excellent, and in the main practically beyond improvement.

It is safe to say that there is not a book on topography in the English language, or perhaps in any other language, that gives with such clearness and discrimination the amount of detail required for maps intended for various purposes, and the simplest and quickest methods for securing the necessary data. For this reason it is believed that it is eminently fitted for use as a text-book—a rare quality in technical treatises—as well as for a handbook for those actively engaged in topographic work.

The sketches, diagrams and maps are taken from work actually done, thereby establishing confidence in the processes described. In this connection it might be suggested that a word of caution should be uttered regarding the tendency to give the interval of contours that have been *sketched*. Beyond this one point, a careful reading has not disclosed anything but meritorious features in all that pertains to the technical side of the book.

J. H. GORE.

COLUMBIAN UNIVERSITY.

Neudrucke von Schriften und Karten über Meteorologie und Erdmagnetismus herausgegeben von PROFESSOR DR. G. HELLMANN. No. 13, *Meteorologische Beobachtungen vom XIV. bis XVII. Jahrhundert.* Berlin, A. Asher & Co. 1901. 4vo. Pp. 70 introduction and notes + pp. 130, fac-similes. Price, 18 Marks.

This is the latest of these reprints that have been reviewed from time to time in SCIENCE, and its object is to elucidate the beginning of meteorological observations and to eradicate the impression, which is common even among specialists, that with very few exceptions there were no continuous observations before the end of the 17th century. It is here shown that already at the close of the 15th century many series of observations existed, including some simultaneous ones, and it seems probable that regular observations of the weather were made even in very ancient times. The present volume deals with two kinds of records, meteorological observations on land—those without instruments from 1337 to 1645, and those with instruments from 1649 to 1700—and observations made at sea between 1492 and 1700.

The earliest journal of the weather extant is that kept by William Merle at Driby, in Lincolnshire, England, between the years 1337 and 1344. The Latin MS. was reproduced in facsimile, with a translation, about ten years ago by the late Mr. Symons, but, as the edition was limited and hardly went outside of England, Dr. Hellmann has thought it worth while to reprint a portion. The next oldest record (1439) is also English, and then come German, Austrian, Italian, Swiss, Belgian, Spanish and Danish observations. It is certainly not known generally that observations in Brazil preceded those in this country, and that the first weather observations in North America were by a Swede, Johann Campanius, on the Delaware River, near Philadelphia, during 1644 and 1645, a summary of the weather for each month being given. The first observations with instruments were readings of the barometer each day during the years 1649, 1650 and 1651 in Clermont (Auvergne) and at the same time at Paris and at Stockholm. Of these only M. Périer's observations in Clermont have been preserved and they are reproduced. The original log-book of Christopher Columbus's first voyage (1492–93) no longer exists, but an extract relating to the change of weather on this side of the Canary Islands, and an account of a West India cyclone encountered on the return voyage, and which is the first description of such a storm, are quoted. There are nine other extracts from logs of early voyages, making, with the observations on land, 36 rare journals. Even if known to students, hitherto these have been practically inaccessible, but now they are presented as nearly as possible in the original form and enriched with copious notes by the best authority on the subject. These reprints have not been put on sale in America, but one or two copies of the current volume may be had at the publisher's price, viz., $4.50, from the Blue Hill Observatory, Hyde Park, Mass.

A. LAWRENCE ROTCH.

Die Pflanzen-Alkaloide. Von JUL. WILH. BRÜHL, Professor an der Universität Heidelberg; in Gemeinschaft mit Edward Hjelt und Ossian Aschen Professoren an der Universität Helsingfors. Mit Eingedruckten Abbildungen. Braunschweig, F. Vieweg und Sohn. 1900. Mk. 14.00.

The discovery of plant alkaloids belongs to the early part of the nineteenth century, and their subsequent study and investigation rank among the important achievements of modern chemistry. In 1803, Derosne, a French apothecary, obtained impure morphine from opium. In 1805, Sertürner, a German apothecary, isolated the pure alkaloid and, in 1817, recognized its basic character and showed it to be the active principle of opium. Since that time the study of alkaloidal chemistry has been steadily pro-

gressing, until from certain plants, as cinchona and poppy, at least twenty different alkaloids have been obtained.

The present monograph is a separate edition of Volume VIII. of 'Roscoe & Schorlemmer's Lehrbuch der organischen Chemie,' and treats of the plant alkaloids apart from the synthetic alkaloids and ptomaines. The author has divided this class of the alkaloids into certain fundamental groups, but has wisely not attempted to extend the classification further, having subdivided them according to the plants or families in which they occur. The main divisions are as follows: I. Pyrrolidin group, hygrine. II. Pyridin group, trigonellin, piperin, chrysanthemin, nicotin, sparteine and cytisin, alkaloids of the Solanaceae, jaborandi, areca nut, conium, coca leaves and bark of the root of pomegranate. III. Chinolin group, cinchona, strychnos and curare alkaloids. IV. Isochinolin group, alkaloids of opium, hydrastis, berberis and corydalis. V. Alkaloids of unknown constitution as in ergot, Lycopodiaceae, Coniferae, Gnetaceae, Liliaceae, Apocynaceae, Aristolochiaceae, Buxaceae (Cactaceæ), Lauraceae, Papilionaceae, Loganiaceae, Papaveraceae, Ranunculaceae, Rubiaceae, Rutaceae, and including glyco-alkaloids and other miscellaneous alkaloids.

Of the more than one hundred alkaloids, the constitution of only a comparatively few is known. In his treatment of these principles, Professor Brühl gives the following data concerning them: History, occurrence, preparation or method of isolation, physical and chemical properties and, wherever possible, the constitution, synthesis and the salts which have been studied.

Concerning the origin and purpose of the alkaloids in plant life, the author seems to agree with Guareschi that they are in the nature of waste products of the living protoplasm and that when once produced they are not again assimilated. It may be said, however, that this view is contrary to the recent researches of Barth, who has shown that in the seeds of *Datura stramonium* L. and *Conium maculatum* L. the alkaloids are located in the nucellus and that after germination they disappear. It would appear, therefore, that they, in some instances at least, like the glucosides, are to be considered in the nature of reserve products. Then, too, the recent discovery of the glyco-alkaloids seems to favor this view.

The author has shown a masterly treatment of the chemistry of the plant alkaloids and the book is welcome as an important contribution to the subject; it is not only of special interest to the chemist and apothecary, but also to the physician, more particularly the therapeutist, as it is being shown that the constitution of chemical compounds has a more or less definite relation to physiological action.

Henry Kraemer.
Philadelphia College of Pharmacy.

ENZYMES AND THEIR APPLICATION.*

A volume of 217 pp., 8vo, has recently been added to l' Encyclopédie Scientifique des Aide-Mémoire, by M.-E. Pozzi-Escot, editor of the Revue Générale de Chimie pure et Appliquée, on the subject of enzymes and their application. The book is written, as the author states in the preface, for engineers and chemists, and not for biologists. The first part of the book, including nine chapters, deals with the general problems of enzymology, classification of enzymes, secretion, chemical composition, general properties, mode of action, etc. There are some statements in the text which physiologists at least could hardly accept as facts without more proof—for example, on p. 9, that enzymes are transformed vegetable albuminoids, or on p. 17, that enzymes are immortal, and on p. 50, that the secretion of diastase depends simply on the food furnished the cell, etc. The writer's use of the word diastase is also inconsistent. Following Duclaux he uses it most often as a general term equivalent to enzyme, but on pp. 42–43 it is used as equivalent to amylase. On p. 50 amylose is used when amylase was evidently intended, also rhamnose where rhamnase was intended (p. 28). Similar typographical errors are painfully numerous.

The second part of the book deals with enzymes in their industrial applications. This, like the first part of the book, is too briefly dealt

* 'Les Diastases et Leurs Application,' par M.-E. Pozzi-Escot. Gauthier-Villars-Masson et Cie., Paris, 1900.

with to make it valuable as a handbook, but the work will serve a good purpose in stimulating a desire on the part of the reader to know more of the subject and lead him to examine some of the more complete works.

ALBERT F. WOODS.

THE CYCLOPEDIA OF AMERICAN HORTICULTURE.*

IT is scarcely a year since the first volume of Bailey and Miller's Cyclopedia of American Horticulture appeared. The third volume, bringing the work down to page 1486, has now come from the press, and there is reason to hope that the concluding volume will not be delayed much beyond the end of the summer. Considering the large number of persons who have written 'copy,' the many illustrations to be selected and prepared, and the extent of the work, this promptness of publication is not only deserving of commendation but quite remarkable.

What has been said of the quality of the earlier volumes (SCIENCE, June 1 and August 10, 1900) applies equally to the one now under consideration. Perhaps the general reader will be most interested in the excellent brief horticultural treatment of the States the names of which begin with N to P—therefore comprising most of the great horticultural States of the country—and of the Philippines and Porto Rico, and in the articles on parks, perfumery gardening, photography as applied to horticulture, physiology of plants, plant breeding, and the correct methods of potting and pruning plants. The most extensive botanical monographs are those of *Opuntia*, *Pinus*, *Populus*, *Prunus*, *Pyrus* and *Quercus;* and the most important horticultural monographs, aside from some of these, are those of the Orange, Peach, Pear, *Pelargonium*, Pecan and *Primula*.

T.

SOCIETIES AND ACADEMIES.

THE AMERICAN PHYSICAL SOCIETY.

AT the meeting of the Society, held at Columbia University, on April 27th, Professor A. A. Michelson, of Chicago, was elected president to fill the vacancy caused by the death of Professor H. A. Rowland, and Professor A. G. Webster, of Clark University, was elected vice-president. The following resolution was adopted and made a part of the minutes:

The Physical Society desires to record its deep sense of sorrow for the death of its late president, Professor H. A. Rowland, and its appreciation of his services to science. By his brilliant researches he did much to advance our knowledge of physics, and by his work as a professor he stimulated many students to greater zeal for accurate scholarship and scientific investigation. His interest in the Society was shown from its beginning, and it owes much to the care with which he watched over the organization. By his death the Society, the science which it represents, and our country have sustained a loss which will be severely felt.

At the same meeting of the Physical Society Professor S. W. Stratton gave an account of the organization of the National Bureau of Standards which is to be established at Washington, and which, it is hoped, will prove of great value both to the scientific workers of the country and to manufacturers.

A paper by Mr. Bergen Davis on a 'New Phenomenon produced by Stationary Sound Waves' described some interesting quantitative experiments with organ pipes. The apparatus and methods employed by Mr. Davis gave results in close accord with what theory would predict, and they make it appear possible to bring the experimental study of these subjects on to an exact quantitative basis.

Mr. H. J. Hotchkiss presented a paper on the 'Counter E. M. F. of the Electric Arc,' giving an account of an experimental study of one phase of this much-discussed question. Mr. Hotchkiss employed an oscillograph, of a type which he has developed and used in numerous previous investigations, to determine whether the arc contains a counter electromotive force which lasts for an appreciable time after the current has been removed. The period of the needle of the oscillograph was about 1/5,000 of a second, and a study of the curves obtained by it has led Mr. Hotchkiss to the conclusion that if a counter electromotive force does exist, which lasts as long as a ten-thousandth of a second after the current is broken, then the

* Bailey, L. H. and Miller, W. Cyclopedia of American Horticulture. N–Q. Pp. xv + 432. Pl. 11 + ff. 606. New York, 1901. The Macmillan Company. Price, $5.00.

average value of this E. M. F. cannot exceed $\frac{2}{3}$ of a volt. The paper also described experiments to determine the conductivity of the arc after the circuit was broken. The conductivity was found to depend upon the direction in which current was sent through the arc, and the results seem to indicate something in the nature of a counter E. M. F., whose value is less than one volt.

Professor A. G. Webster showed a method by which the Maxwell top might be used to indicate the path of the invariable axis in a body moving under the influence of no forces. A second paper by Professor Webster described quantitative experiments with a top. The traces obtained from the top under various known conditions were found to agree satisfactorily with the predictions of theory.

A paper by Professor E. L. Nichols on the 'Efficiency of the Acetylene Flame' gave the results of experiments on this subject since the presentation of Professor Nichols' previous paper in June. The values obtained at that time have been only slightly modified by the later work.

A paper on the 'Specific Heats of Electrolytes,' by Professor W. F. Magie, gave a formula for computing the specific heat in the case of solutions in which electrolytic dissociation occurs. A comparison with experimentally determined values showed an extremely satisfactory agreement.

A paper by Mr. J. W. Miller, on the 'Elastic Properties of Helical Springs,' describing numerous experiments on this subject, completed the program.

Ernest Merritt.

CHEMICAL SOCIETY OF WASHINGTON.

The 126th regular meeting was held April 11th, when the following program was presented:

'A New Method for the Estimation of Cane Sugar, in presence of Lactose,' by L. M. Tolman. Benzolsulphinide was used as the hydrolyzing agent, because it has no action on the rotation of lactose, even after heating for several hours, while a solution of sucrose is completely inverted in 30 minutes, by use of one-half gram of the sulphinide. The results obtained showed that it was a satisfactory and accurate method. The method used in condensed milk was as follows: Twice the normal weight of the milk was weighed into a 200-cc. flask and 10 cc. of a 10-per-cent. solution of citric acid added to coagulate the casein. The liquor was then filtered, 75 cc. of the filtrate measured into a 100-cc. flask, one half gram of saccharine added and, after shaking, in order to break up the lumps, immersed in a boiling water bath for 30 minutes. Two cc. of acid mercuric nitrate were then added, the solution made up to volume, filtered and polarized at as near 20° C. as possible. The direct reading was taken in the ordinary way and the volume of precipitate corrected for by double dilution. The results obtained were very satisfactory.

'Classification of Alkali Soils,' by Frank K. Cameron. The views presented in this paper may be summarized as follows: (1) A classification as black alkali or white alkali, depending upon the presence or absence of sodium carbonate, is inadequate in view of our present knowledge of alkali phenomena. A more comprehensive classification is desirable. Such a classification appears to be possible on chemical grounds, considering alkali conditions as the result of the action of aqueous solutions of certain soluble salts upon less soluble salts. (2) The action of sodium chloride solutions upon gypsum is the predominating feature in certain areas and seems to be well typified by the conditions in the valley of the Pecos in New Mexico. The solubility of the gypsum is apparently much increased by the presence of the sodium chloride due to the formation of the soluble salts, sodium sulphate and calcium chloride. In such an area practically the only salts which will have to be considered in the ground solutions are sodium chloride and sodium sulphate, as well as calcium sulphate. Calcium chloride is sometimes found concentrated to a considerable extent, but usually in localized and generally small spots. Owing to its keeping the soil of these spots moister and, therefore, darker than the surrounding soils, such spots are locally known as black alkali spots. (3) The action of solutions of sodium chloride upon calcium carbonate is the predominating feature of some areas. The region about

Fresno, Cal., seems to furnish a good illustration of this class. As a result there is always found a greater or less formation of sodium carbonate, the soluble and very noxious component of black alkali, and the very soluble calcium chloride. Such regions are generally further characterized by the presence of a hardpan at a distance of a few feet below the surface and generally parallel to it, the cementing material of which is calcium carbonate. In such areas there is a tendency toward an accumulation of the soluble carbonates at the surface of the soil. Calcium chloride accumulations, in spots of comparatively restricted area, are frequent accompaniments and are often mistaken for bad black alkali spots, although the presence of soluble carbonates in more than very small quantities is an impossibility. (4) The class of alkali most commonly encountered is that in which the predominating feature is the simultaneous action of solutions of sodium chloride upon gypsum and calcium carbonate. In such an area the formation of soluble carbonates can take place to only a very limited, generally negligible, extent. The apparent increase in the solubility of the gypsum is also much less than when the calcium carbonate is not present. The alkali of the Salt Lake Valley appears to be a good illustration of this type. (5) Much less frequently other types of alkali are encountered, as at Billings, Mont., where the soluble material in the soils appears to be almost entirely sulphates. (6) Modifications of the types described above are more or less frequently found. They may possibly be of such importance as to warrant a separate classification, as, for example, the conditions found to exist in the valley of the Sevier, Utah. (7) The classification here proposed is believed to be comprehensive and is founded on scientific principles. It is elastic and will readily admit of modifications. Principles other than those now recognized in it may be introduced without the accompaniment of radical changes. It can be made as specific as the advance of our knowledge from time to time will justify.

'Chemical Examination of Alkali Soils,' by Atherton Seidell. In this paper the author pointed out the necessity for uniform methods in the examination of the water-soluble compounds of alkali soils, in order that the work of various investigators may be compared. A description of the procedure and methods in use in the U. S. Department of Agriculture was given, with a full discussion of the basis therefor. The unique features are the preparation of the solution for analysis, the preliminary determination of the salt content, by means of the electrolytic bridge, and the determination of carbonates, bicarbonates and chlorides. The statement of the results was also discussed at length.

L. S. MUNSON,
Secretary.

THE ONONDAGA ACADEMY OF SCIENCE.

THE 46th regular meeting of the Society was held in the Historical Rooms, on April 19, 1901.

The first paper was by Professor J. D. Wilson, entitled 'The Fauna of the Goniatite Limestone.' In most places this formation consists of two layers of rock scarcely more than two feet in thickness, but exceedingly rich in goniatites and other cephalopods. He had collected 18 varieties of goniatites, orthocerata, and related forms, nearly all of them confined to the upper layer of limestone. Recently he had found several specimens, one a coiled form, evidently related to *Gyroceras transversum*, and ornamented with nodes, but having a cross section distinctly decahedral. The name *Thoracoceras Wilsoni* is suggested. In the discussion Professor Philip F. Schneider called attention to a much smaller and less prominent fauna of the limestone, which is principally confined to the lower layer. It consists of 3 gasteropods, 2 pteropods, 1 brachiopod and 1 trilobite, thus increasing the list to 25 specimens.

The second paper, entitled 'Recent Theories as to the Cause of the Glacial Period,' was given by Dr. T. C. Hopkins of Syracuse University. He spoke briefly of several of the recent theories and carefully described the 'Atmospheric Theory.' This theory is based on the principle that slight variations in the amount of carbonic acid and watery vapor present in the atmosphere produce grave changes in its temperature, and he would entirely account for the great differences in the tempera-

ture of the past in this manner. The detail of the theory resolves itself into a question of accounting for the differences in the amount of carbonic acid present, all of which was carefully worked out and described by Dr. Hopkins.

A plan for the federation of all local societies with kindred interests was favorably discussed.

Philip F. Schneider,
Corresponding Secretary.

THE BACONIAN CLUB, STATE UNIVERSITY OF IOWA.

The following formal papers have been read during the current year:

'Forestry in Iowa': Assistant Professor B. Shimek.

'The Extent and Significance of Food Adulterations': Dr. E. W. Rockwood.

'The Geology and Scenery of the Pipestone Region': Professor Samuel Calvin.

'Some Features of the Architecture in Westminster Abbey': Dr. J. G. Gilchrist.

'Jelly Fishes and their Relation to the Hydroid Colony': Professor C. C. Nutting.

'Three Famous Problems in Geometry': Dr. J. V. Westfall.

'A Sketch of the Geology of Canada': Mr. R. D. George.

'The Rôle of Insects in the Spread of Diseases': Dr. W. L. Bierring.

'The Mechanics of a Harp String': Professor Laenas G. Weld.

'Concerning the Scope of University Training': Professor Launcelot W. Andrews.

'The Psychology of Profanity': Professor G. T. W. Patrick.

'The Lost Art of Wood Engraving': Mr. John Springer.

'Some Features of the Road Problem': Professor A. V. Sims.

'The Inscribed Polygon of Seventeen Sides': Assistant Professor Arthur G. Smith.

'The Sympathetic Relation of the Two Eyes': Dr. F. J. Newberry.

'Measurement by Light Waves': Mr. Charles F. Lorenz.

'The Pecuniary Economy of Foods': Mr. A. M. Goettsch.

'Twentieth Century Protoplasm': Professor T. H. Macbride.

'The Psychological Theory of Organic Evolution': Dr. H. Heath Bawden.

'Photographic Optics': Professor A. A. Veblen.

'The Modern Theory of Solution': Dr. Carl von Ende.

'Railroad Construction': Mr. W. D. Weeks.

'The Causes of Blindness in Iowa': Dr. L. W. Dean.

Several of the above papers were original contributions to science and have been or will be published.

Among the voluntary reports that have been given during the year the following deserve mention as first announcements: December 7, Professor C. C. Nutting reported on the discovery of a new method of reproduction among the hydro-medusæ. The hydranth has been seen to proceed from the proboscis of the medusa, by a process of budding. December 14th, Professor A. A. Veblen exhibited a new copying-camera table which is capable of all needed adjustments. January 4th, Dr. J. G. Gilchrist reported upon the successful treatment by trephining of three cases of epilepsy of long standing. February 15th, Professor Launcelot W. Andrews exhibited a model to illustrate the process of electrolysis. The same model illustrates Faraday's law of the decomposition of chemical substances. April 26th, Miss Mabel Williams reported the discovery of 'the area-volume illusion,' according to which any dimension of a surface seems larger than the corresponding line and one face of a volume seems larger than the corresponding plane surface. The speaker has demonstrated that the illusion is due to the presence of the judgment 'there is more of it,' which exerts a subconscious influence in the perception. October 12th, the secretary exhibited a new ergograph, and April 19th, new apparatus employed in the study of the voluntary control of the pitch of the voice in singing and speaking.

C. E. Seashore,
Secretary.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

At the meeting of the Academy of Science of St. Louis on the evening of May 6th, twenty-two persons present, Mr. C. F. Baker presented an embryological demonstration, including gross and microscopic specimens, covering the development of the chick during the first forty-eight hours of incubation, intended to illustrate a working course in embryology for high schools.

One person was elected to active membership.

William Trelease,
Recording Secretary.

ELISHA MITCHELL SCIENTIFIC SOCIETY.

AT the 135th meeting of the Society on May 4th, the following papers were read:

'Transit Methods for Laying Sewer Grades': Mr. Wm. Cain.

'Acid Crystallization': Mr. Charles Baskerville.

'The Probable Complexity of Thorium': Mr. Chas. Baskerville.

'The Recent Geological Formations of the Mississippi Valley': Mr. J. A. Holmes.

CHAS. BASKERVILLE,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE LARYNX AS AN INSTRUMENT OF MUSIC.

TO THE EDITOR OF SCIENCE: In this week's number of SCIENCE Professor Joseph Le Conte remarks upon Professor Scripture's description of the mode of action of the vocal chords, and quotes from a work of his own to show that the larynx 'cannot be likened to a stringed instrument nor to a reed-pipe,' continuing, "It is strange that no one has thought to liken it to an ordinary horn; a stage horn, or better, a French horn."

In Helmholtz's 'Tonempfindungen,' of which the first edition was published in 1862, occurs, under the caption, 'Membranöse Zungen,' the following statement: 'Als musikalische Instrumente kommen nur zwei Arten solcher membranöser Zungen in Betracht, nämlich die menschlichen Lippen beim Anblasen der Blechinstrumente und der menschliche Kehlkopf in Gesange.'

This is the exact comparison suggested by Professor Le Conte. There follows a minute description of the mode of action of the vocal chords, and of the action of the lips in blowing a horn, which has never needed any improvement or correction. Both these cases are, very properly as it seems to me, classified under reed pipes, the sorts of reeds described being of great variety. The model pictured at the head of the section, for the study of membranous reeds, is certainly, as I think will be admitted by any-one who has made one, a very convincing demonstration of the mode of action of the larynx. Professor Scripture's elastic cushions are certainly to be classified as reeds.

ARTHUR GORDON WEBSTER.

CLARK UNIVERSITY, May 17, 1901.

THE NEW COMET.

TO THE EDITOR OF SCIENCE: In SCIENCE for May 3d, page 717, appears an announcement of the discovery of the new comet, to which is added a section, stating that Professor Frost, of the Yerkes Observatory, had observed the comet on the morning of April 27th, just before sunrise. The last number of the *Astronomical Journal* also contains a similar statement, saying the comet was seen by him 20 minutes before sunrise, half an hour afterwards, and 15° north of the sun.

Here at the Naval Observatory two of the computers, and also I, myself, hunted diligently for the comet, both in the morning and evening, for several days after the receipt of the first telegram, and until we had positive information on the direction of motion.

Now that a set of elements of the comet has been received, it is perfectly clear that whatever Professor Frost sighted on April 27th, it was not the comet. On that day the object was 13° *south* of the sun, and very close to it in right ascension.

Moreover, as seen from the Yerkes Observatory, it would not rise until about 40 or 45 minutes after the sun, as any one can easily demonstrate by computing the place of the comet for that day, the semi-diurnal arc for it and the sun, for Yerkes Observatory, and take the difference between those two quantities.

GEORGE A. HILL.

NAVAL OBSERVATORY, WASHINGTON, D. C., May 16, 1901.

THE TEACHING OF PHYSIOLOGY IN THE PUBLIC SCHOOLS.

ABOUT two years ago I wrote a letter for SCIENCE concerning the text-book in physiology adopted by the State Board and used throughout the public schools of Kansas. Much dissatisfaction has been expressed by the more intelligent teachers of the State, but there is, nevertheless, no redress—the book must be used as a text in every school in the State.

The results may be inferred. I can exemplify them no better than by giving some of the actual answers to questions in physiology by high school candidates who had just been passed in physiology in the grammar grades.

'Pleurisy is a disease of the skin'—'an indication that some nerve has been affected.'

'Alcohol, tobacco and opiates thicken the blood of the nerves.'

'The respiratory center is in the heart.' 'The heart is the center of respiration.'

'Residual air is the air in the heart.'

'The body should be bathed frequent'—'should be bathed at least once a year.'

'Appendicitis and pleurisy is a condition of the throat.'

'The blood is carried to the liver through the right and left auricles.'

'The meatus auditorius is in the intestines'—'is an artery leading from the heart'—'is in the eye'—'is a tube in which the blood passes through before entering the stomach.'

'The patella is a network of small blood vessels'—'is the lining of the abdomen'—'is a tube in the chest'—'is a muscle over the knee.'

'The motores oculi is in the veins'—'is an organ of voice.'

'The mitral valve is at the lower end of the stomach'—'is located in the liver.'

'Excretion is mingling with saliva,' etc., etc.

Such absurdities are by no means rare in the Kansas schools. For several years it was the writer's duty to pass upon the papers in physiology of candidates for the State teachers' certificate, and many answers as ridiculous as any of the above, were observed. Thus: to the question 'Why does the human body cease to grow in stature after about the twenty-fifth year?' the reply was almost invariably, 'Because it has got its full growth.' Four out of fifteen answered the question as to what the lymphatic system is by saying that it is a system of vessels that take up the impurities of the blood and discharge them into the kidneys! It was the rare exception that the papers came up to the standard of a respectable high school.

The worst of it all is that many intelligent people defend such ignorance by saying that you must not expect teachers in the public schools to be experts in physiology. Is it not time that such 'science' is banished from the public schools? I do not know whether Kansas is an exception in this particular, as it is perhaps in some others, to the other States of the Union. Certain it is, however, that such defects cannot be ascribed to the public school system of the State in general, for I honestly believe that this stands on a higher plane than in a majority of the other States. Is public school physiology everywhere a farce?

S. W. WILLISTON.

SHORTER ARTICLES.

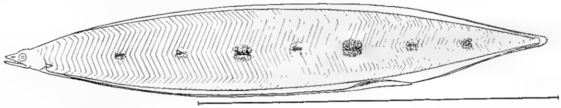
UNILATERAL COLORATION WITH A BILATERAL EFFECT.*

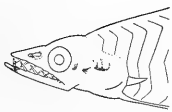
WHILE describing the larval eels or Leptocephali belonging to the United States National Museum two specimens claimed especial attention. Structurally these two specimens are very different and might readily be referred to distinct species. In one the nares are approximated, and the pectorals are well developed, in the other the nasal openings are wide apart and the pectorals have disappeared. The index that pointed to the probability that the two specimens were different stages of the same species is their unique coloration. There are eight large black spots much larger and much more conspicuous than the color markings of any other Leptocephalus. One of these is located over the alimentary canal a short distance in front of the anus. The others are along the side. Each one of these spots is formed by a single enormous chromatophore extending laterally over three or four somites. Sometimes a few minute chromatophores are to be found at the margin of the large one. There are three of these large chromatophores on the left side of the body and four on the right. In each case the spots of one side are arranged at irregular intervals, but in both cases the spots of the one side alternate with the spots of the other side, so that together they form, even in the alcoholic specimens of these transparent

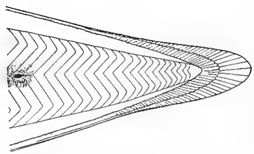
* Contributions from the Zoological Laboratory of the Indiana University, No. 45.

creatures, a series of seven spots placed at nearly regular distances along the middle of the side. The effect is precisely the same as if the seven spots were repeated on the two sides.

In opaque animals the color markings of the two sides approach bilateral symmetry. In the present case the markings are strikingly asymmetrical in that there are three spots on one side and four on the other. This asymmetry in the number of spots on the two sides and their positions at irregular distances from each other makes it quite certain that their arrangement







on opposite sides so as to alternate and form a series at more or less regular intervals is not accidental but the normal condition, *i. e.*, a mutual adaptation in the location of the spots of the two sides. This adaptation of the two sides to each other is emphasized in the younger specimen where the first two spots are on the right side, leaving the first forty segments of the right side without a spot.

The following are the details of the distribution of the spots on the somites, counting from the pectoral backwards:

Number of segments between the centers of successive spots.	Number of the segments and the sides on which the spots occur.
YOUNGER SPECIMEN:	
12	15–16–17 R
13	27–28–29 R
11	40–41–42 L
11	51–52–53 R
14	62–63–64–65 L
15	76–77–78 R
	91–92–93 L
OLDER SPECIMEN:	
12	12–13–14 R
12	24–25–26 L
12	36–37–38 R
10	48–49–50 L
13	58–59–60 R
17	71–72–73 L
	87–88–89–90 R

The two specimens differ structurally as follows:

A. Body more elongate than in *AA*; pectorals a mere ridge; nostrils remote from each other for a distance nearly equal to the diameter of the eye; leptocephalous teeth wanting; lower jaw projecting, its tip rounded and entering the profile; no pigment spots about the head; depth $8\frac{3}{5}$ in length, head distinctly more than half the depth of the body, nearly 11 in the length; eye 7 in head, $1\frac{1}{2}$ in snout; segments $73 + 43$. One specimen 51 mm. long. New Providence (type).

AA. Body elliptical: pectorals well developed: nostrils not yet separated: leptocephalous teeth: jaws nearly equal: a pigment spot near the end of the lower jaw, another within anterior nares, two succeeding each other between the lower margin of the pupil and the lower margins of the auditory capsule: depth 6 in the length: head little less than half greatest depth: eye five in head: segments $76 + 38$.

One specimen 38 mm. long. Albatross Station 2566.

The *Leptocephalus* has not been referred to

its adult form and may be termed *Leptocephalus diptychus.*

Clarence Kennedy.
University of Indiana.

VELOCITY OF IONS FROM ELECTRIC ARCS AND FROM HOT WIRES.

Much interest is being shown at present concerning ionization of gases and 'electron' theories of electricity. An investigation now in progress promises to throw further light on this subject, in fact to change one idea which has been held. It has been stated by eminent authorities that in the case of discharge through gases the negative ions always go faster than the positive under the same conditions. The present investigation shows that this is not always the case and a brief account of it may not be amiss.

The work had its origin in an attempt to explain the phenomena of the electric arc. It was shown in the *Physical Review** that all the phenomena of the arc could be explained by assuming, first, that the current in the arc was carried by ions, and second, that the positive ions move the more rapidly. The second part of this hypothesis did not at first seem probable, since in all cases which had previously been investigated the negative ions had been found to move the more rapidly. Two sets of experiments were, however, given as tending to substantiate that hypothesis, but neither of them could be considered conclusive. †

More recently experiments have been performed with ions drawn out from an arc by a charged body in the neighborhood. ‡ The positive ions in this case were found to have the greater velocity. Quite recently the same fact has been shown by an application of a method used by Zeleny * for finding the velocity of ions produced by X-rays. These methods are entirely independent and the agreement of the results in the two cases leaves little reason to doubt the correctness of the conclusion that the positive ions here move the more rapidly.

Of course, this is not a proof that the positive ions in the arc itself move more rapidly than the negative, but since such an assumption would explain the phenomena of the arc and since the positive ions just outside the arc do have the greater velocity, it seems reasonable to assume that they do also within the arc.

It opens up, however, a still more interesting field of inquiry, *i. e.*, that concerning the condition under which the positive ions show this peculiarity. The discharge from hot platinum and iron wires was accordingly investigated. It has long been known that positive electricity escapes from hot metals easier than negative. An examination of the velocity of the ions from the hot metals showed that here also the positive ions move the more rapidly. Both the methods used in the previous investigation led to the same conclusion.

But in all these cases the action is complicated by the fact that both gases and solids are present. For example, in the case of discharge from hot platinum wire atoms of platinum are no doubt given off, since it is a well-known fact that platinum wire when heated to a white heat decreases in weight. † It may be that because of some contact difference of potential the negative ions of the metal never escape from the metal. A comparison of positive ions of one substance with negative of another would not be of great value. One would wish to know whether the positive ions move faster than the negative ions from which they have been separated.

The case of the arc is still more complicated, for many different solid and gaseous substances enter into the arc. The investigation by Arons ‡ on the arc between metals in H and N at different pressures shows that both the terminals of the arc and the gases about it must be considered.

* *Phys. Rev.*, 10, 151.

† Since publishing the above-mentioned article I find that part of the work there described had already been described by Dewar (*Chem. News*, 45, 37). My own work was performed without knowledge of that done by Dewar, and the method used was not the same as his. The results of the two investigations agree fully. The explanation of the results offered by myself was not suggested in his article.

‡ *Phys. Rev.*, 12, 137.

* *Phil. Trans. Roy. Soc. Lon.*, 195, 193.

† *Wied. Ann.*, 37, 319.

‡ *Drude Ann.*, 1, 700.

Fortunately one case has been studied which is not thus complicated, *i. e.*, the arc in mercury vapor between mercury terminals. In this case only one element is to be considered, and here Arons * found that the greater fall of potential was at the anode. In the light of the work now described we may interpret this to mean that the positive ions in such an arc move the more rapidly.

Warburg † found that in case of discharge in a vacuum tube containing some mercury vapor the fall of potential at the cathode was approximately the same as it was in nitrogen. Arons in discussing this calls attention to the fact that when discharge is taking place through a gas the greater fall of potential is at the cathode, when through a metal vapor at the anode. Possibly we may now modify this statement and say that when *gases are ionized the negative ions move the more rapidly, but that when metal vapors are ionized the positive ions move the more rapidly.* All the facts that have thus far been observed could be explained by such a hypothesis. If this should be shown to be correct, it will no doubt lead us to modify somewhat our ideas concerning the relation of metals to electricity.

C. D. CHILD.

† *Wied. Ann.*, 40, 10.

MODULUS OF CONSTANT CROSS SECTION.

THE longitudinal rigidity of a solid, represented by Young's modulus, depending as it does upon both the volume elasticity and simple rigidity, leaves one condition unprovided for *viz.:* the case of longitudinal extension with cross section remaining unchanged. This case probably does not occur with an unrestricted stress, but it is easily conceived in theory. I can find no mention anywhere of a modulus of constant cross section, and have undertaken to approach the problem in this wise. Add to Young's modulus that fraction of the simple rigidity represented by Poisson's ratio. This preserves the longitudinal rigidity and restores to the new modulus the numerical measure of that portion of the strain called out by the change in lateral dimensions.

If this be a true modulus, it offers an easy method of determining approximately the mechanical equivalent of heat, and provides a practical experiment for laboratories not supplied with costly and complete apparatus. Thus a brass wire of density 8.5; sp. heat, of .09, coefficient of expansion .000018, volume elasticity 10×10^{11}, simple rigidity 3.7×10^{11}, and Young's modulus 10.4×10^{11} gives roughly,

$$\frac{\left[10.4 \times 10^{11} + \left(\frac{22.6}{67.4} \times 3.7 \times 10^{11}\right)\right]\frac{1}{2} \times .000018}{\frac{8.5 \times .09}{3}} = 4.1 + \times 10^{7}$$

as the value of the calorie in C. G. S. units.

BENJ. H. BROWN.

NOTES ON INORGANIC CHEMISTRY.

WITHIN the past few years much has been added to our knowledge of the chemistry of the alums. To the aluminum, chromium, iron, gallium, and indium alums have been added those of titanium, vanadium, manganese, and cobalt. This completed the series of alums of the metals of the period from titanium to cobalt, but beyond this no alums were known of metals outside of the third group. In the last number of the *Zeitschrift für anorganische Chemie* Professor Piccini of Florence, the discoverer of the titanium and vanadium alums, has described a series of rhodium alums, including those of potassium, ammonium, rubidium, cesium and thallium. This is of peculiar interest, since rhodium belongs to a period in which no alums have been known, and opens the question as to whether there may be other alums in the same period, which includes molybdenum and columbium. Piccini is at present endeavoring to form iridium alums, which the preparation of the rhodium alums makes seem possible.

IN a paper in the last *Berichte* of the German Chemical Society, on radio-active lead, Professor K. A. Hofmann of Munich and Eduard Strauss describe two new substances which appear to be new chemical elements. Both are found in the lead chlorid obtained from pitchblende, and are separated from the lead by fractional crystallization. The one substance possesses no radio-activity and resembles some-

what ruthenium. Its combining weight is 50.46, and hence if bivalent it would have an atomic weight of 100.92. In this case it would be the missing eka-manganese, but the authors put this forward merely as a suggestion, pending a more thorough investigation. That which would tell most strongly against this supposition is the fact that the new substance forms a white sulfate which is insoluble in water and in dilute sulfuric acid, and stable up to a temperature of 400° to 500°. The second new substance described by Hofmann and Strauss is found in the lead chlorid, both from pitchblende and from bröggerite. This substance is radio-active, though the authors express doubt as to whether the activity of the lead from these minerals is due solely to the presence of this new substance. It appears to have a combining weight of 86, from which an atomic weight of 172 would follow, provided the metal is, as would seem probable from its resemblance to lead, bivalent. It might then be a metal of the fourth group, between tin and lead, and the representative of the period, none of whose members are definitely known. Of the compounds of this element, if such it be, the sulfate alone shows radio-activity. After the action of the kathode rays the substance shows a fluorescence, which lasts for upwards of two minutes.

THE same number of the *Berichte* contains the description by Professor Hoffman and W. Prantl of a new element in the euxenite from Brevig. This euxenite, which is a complex silicate, titanate and columbate of the rare earths, iron, and aluminum, contains about two per cent. of what is supposedly zirconia. Hofmann finds that half of this is a new oxid, differing from zirconia, by its insolubility in ammonium carbonate, its giving no color reaction with curcuma, and having a combining weight of 44.4, which is nearly double that of zirconium. The atomic weight of the new element, if quadrivalent like zirconium, would be about 178. The same mineral seems also to contain another hitherto unknown element, which bears some resemblance to tantalum, but which has not yet been carefully examined.

IN spite of the incredulity with which his claims to convert phosphorus into arsenic and antimony have been received by chemists, Fittica still continues his work upon the subject. In his latest experiments he heats amorphous phosphorus with lead oxid and boron. At 140° water is formed and after heating to 205° the residual mass is found to contain lead sulfate and the borid of nitrogen. If boric acid anhydrid is used in the place of the litharge, water, sulfuric acid and the borid of nitrogen are likewise formed, but also arsenic and sometimes antimony. From these experiments Fittica concludes that amorphous phosphorus is a compound of nitrogen, sulfur and hydrogen, and he assigns to it the formula N_2SH_2. He does not, however, furnish satisfactory proof that this represents the actual quantitative composition of phosphorus. He also admits that when amorphous phosphorus is oxidized with nitric acid no trace of sulfuric acid is formed.

J. L. H.

BOTANICAL NOTES.

INTERNATIONAL BOTANICAL ASSOCIATION.

A CALL, signed by sixteen botanists of Europe and America, has been issued for a meeting of the botanists of the world at Geneva, Switzerland, on the 7th of August next, for the purpose of organizing an International Botanical Association. In the call it is stated that the chief object of the Association will be the foundation of a bibliographic periodical, criticizing in a perfectly impartial manner all botanical publications in such a way that the more important shall be separated from those which are of less value. Other advantages to be derived from the proposed organization are presented, and correspondence with the secretary, Dr. I. P. Lotsy, of Wageningen, Holland, is solicited.

STOCK-POISONING PLANTS.

THE Division of Botany of the United States Department of Agriculture has recently issued a valuable bulletin (No. 26) dealing with the plants which are known to be poisonous, or which are thought to be poisonous to stock in the State of Montana. About twenty-five pages are given to a general discussion of the conditions under which poisoning occurs, and of remedies and their application. Then follow about sixty pages devoted to a few plants of the

greatest importance, viz.: death canas (*Zygadenus venenosus*), larkspurs (*Delphinium* of two species), water hemlock (*Cicuta occidentalis*), loco weeds (*Aragallus* sp.) and lupines (*Lupinus* sp.). The first is said to be the most important of all the plants reputed to be poisonous to stock in Montana. It grows everywhere in Montana in moderately moist places on open ranges, and outside of the State is found from British Columbia to South Dakota, Nebraska, Utah and California. Feeding experiments show that both leaves and bulbs are poisonous. Two species of larkspurs (*D. glaucum* and *D. bicolor*) have attracted the most attention, although other species are more or less under suspicion. The foliage is the poisonous part in these plants. Water hemlock is usually known as 'wild parsnip' and is commonly supposed to be the garden parsnip run wild, an error, of course. The roots and foliage are poisonous, and cases of poisoning of cattle, sheep and even human beings are reported. This species is very much like the eastern (*C. maculata*) in appearance and action. The loco weeds affect animals quite similarly to the related plants called loco weeds on the Great Plains. The species of most importance is *Aragallus spicatus* which is closely related to *A. lamberti* of the Missouri Valley. Several pretty species of lupines (*Lupinus*) are shown to be poisonous. These are locally known as blue peas, blue beans, wild peas, wild beans, etc., and in spite of their pretty flowers are to be placed among the noxious plants. The report devotes about a dozen pages to poisonous plants of less importance, about as many to suspected plants, and closes with a discussion of some species which have been wrongly accused of possessing poisonous properties. Thirty-six plates help to make this a very valuable and useful report.

NORTH AMERICAN FERNWORTS.

ABOUT twenty years ago Professor Underwood issued a little book on the ferns of the country, which has proved to be so useful that it has been revised again and again, its latest title (sixth edition) being 'Our Native Ferns and their Allies.' From time to time it has undergone considerable changes at the hands of its author, and in its latest form this is most marked. Here the results of the latest studies both in morphology and nomenclature have been used to such an extent that the old-time fern collector will often find himself somewhat dazed and confused, unless he has kept himself well informed as to the tendencies of these later years. Thus to find the common brake under the name of *Pteridium aquilinum* instead of *Pteris aquilina;* to find *Phyllitis* substituted for *Scolopendrium; Dryopteris* and *Polystum* for *Aspidium; Filix* for *Cystopteris; Matteuccia* for *Struthiopteris;* and *Dennstaedtia* for *Dicksonia*, is disquieting for the botanist who learned about ferns twenty or more years ago. It shakes one's faith in the immutability of things to find old friends under unfamiliar names. For the peace of mind of such persons it would be well not to buy the later editions of systematic books, for in all of them—even the most conservative—we find many of these tiresome changes.

In a recent paper ('A List of the Ferns and Fern-Allies of North America north of Mexico, with principal Synonyms and Distribution') published by William R. Maxon in the *Proceedings* of the United States National Museum (Vol. XXIII.) our information as to the Fernworts of North America is considerably augmented. While in Professor Underwood's book the total number of entries is 279, Mr. Maxon brings them up in his list to 307. This increase is mostly due to the separate recognition and enumeration of varieties, and in part to the addition of new species and varieties. Among the new species are *Polypodium hesperum*, from western United States; *Adiantum modestum* from New Mexico; *Dryopteris aquilonaris* from Alaska; *Isoetes heterospora* and *I. hieroglyphica* from Maine; *I. harveyi* from Maine and Massachusetts; *I. gravesii* from Connecticut, besides about as many more new varieties. *Athyrium* is given generic rank and separated from *Asplenium*, carrying with it the species *thelypteroides*, *filix-foemina* and *cyclosorum*. The synonymy is considerably fuller than in Professor Underwood's book, and the ranges are often modified and extended. We note still the omission of Unalaska as one of the stations for *Adiantum capillus-veneris*, although specimens are in herbaria which were collected on that island many years ago. The ranges of *Lycopodium*

clavatum and *L. complanatum* should be so extended as to include Iowa, as shown by Professor Shimek's recent list of Iowa Pteridophyta.

CHARLES E. BESSEY.

THE UNIVERSITY OF NEBRASKA.

MUSEUM NOTES.

PUBLICATIONS OF THE CARNEGIE MUSEUM.

WITH the issue of No. 1 of the *Annals of the Carnegie Museum*, this rapidly growing institution enters upon its career as a museum of publication; the publications are to appear as *Annals* and *Memoirs*, the first in octavo form, the second in quarto, and they are to be published from time to time as material is provided. In the 'Museum Notes,' with which this number of the *Annals* begins, it is stated that the Museum is to re-open the quarry at Como, Wyoming, where Professor Marsh obtained a number of his best specimens, including a number of skulls of Dinosaurs. The first systematic paper is by E. B. Williamson, on 'The Crayfish of Allegheny County, Pa.,' and describes six species. John A. Shafer gives a 'Preliminary List of the Vascular Flora of Allegheny County, Pennsylvania,' stating that it is issued largely as an incentive to others to participate in the preparation of a fuller, more complete catalogue. While the order of arrangement is that of Gray's Manual, the author states that this is selected merely as a matter of convenience and that he is fully in accord with the nomenclature of the most recent authors. The data on which the species are admitted to the list are indicated by means of signs. J. B. Hatcher notes 'Some New and little known Fossil Vertebrates,' showing that *Platacodon nanus* is unmistakably a fish and describing the character of the dermal covering of *Claosaurus*. Of special interest is a description of the principal characters of a primitive rhinoceros, *Trigonias osborni*, of which Mr. Hatcher was so fortunate as to secure an almost complete example, the species having been founded on the anterior part of the upper jaw and a ramus of the lower jaw. The dentition was noted as of a primitive type since three incisors and a canine were present on either side of the upper jaw. The rest of the skeleton agrees with this, the superior molars being simple in their structure, while there are four digits in the forefoot. D. A. Atkinson gives a list of 'The Reptiles of Allegheny County, Pennsylvania,' prefacing the paper with the remark that civilization means the destruction of a certain portion of the natural fauna of a region and that many species now rare in Allegheny County must have formerly been abundant, while two species have been exterminated within the last forty years, these being the prairie and the mountain rattlesnakes. In all, thirty-four species of reptiles are recorded. The concluding paper of the part is by R. W. Shufeldt on the 'Osteology of the Herodiones,' and contains a detailed description of the native genera of the group and with some foreign forms.

THE FIELD COLUMBIAN MUSEUM.

THE *Annual Report of the Director* of the Field Columbian Museum for 1899 1900 shows a marked increase of the collections in the line of anthropology, mainly in the way of material collected from the Hopi Indians and from the western States, through expeditions sent out. In botany is noted the accession of the Patterson herbarium of 30,000 North American plants, and a series of a thousand specimens from California and Colorado. A special form of herbarium case is described and figured which is said to combine freedom of access with security from insects and the exclusion of dust. Good progress has been made in cataloguing and labeling and a large number of books and pamphlets have been added to the library, making the present total somewhat over 24,000 titles. Two courses of eight lectures each were given during the year. The total number of visitors is not stated, but we are told that there was an increase of 42,595 over the previous year. The frontispiece of the report is an excellent portrait of the late George M. Pullman, and there are a number of full-page plates showing some of the ethnological and anthropological exhibits, among them two of Mr. Akeley's fine groups of African antelopes.

THE SOUTH AFRICAN MUSEUM.

PARTS IV. and V. of the *Annals of the South African Museum* are to hand, the former con-

taining a detailed description of 'The Anatomy of *Opisthopatus cinctipes* Purc., with notes on other, principally South African, Onychophora,' by W. F. Purcell, including the color variations, number of legs and distribution of the species. Part V. contains a 'Description of New Species of South African Pselaphidæ,' by Achille Roffray; 'Description of Seven New Species of the Family Mutillidæ,' by L. Péringuez, and 'Description of a New Species of the Genus *Japyx*,' by the same author.

F. A. L.

AQUATIC RESOURCES OF THE HAWAIIAN ISLANDS.

IN compliance with a resolution of Congress, Hon. George M. Bowers, United States Commissioner of Fish and Fisheries, is arranging to send an expedition to the Hawaiian Islands to make a comprehensive study of the fishes and other aquatic resources of those islands. The investigations will be under the immediate direction of Dr. David Starr Jordan, President of Stanford University, and Dr. Barton W. Evermann, the ichthyologist of the Commission, who will have the assistance of a number of experts.

It is the intention to make the investigations sufficiently comprehensive to enable the Commission to publish a very exhaustive report on the subject. The investigations during the present summer will be by shore parties and will pertain chiefly to the following lines:

1. A thorough qualitative and quantitative study of the commercial and shore fishes, mollusks, crustaceans and other aquatic animals and plants. Attention will be given to the actual and relative food values and commercial importance of the different species, their migrations, spawning time and place, food, feeding habits, enemies, maximum and average size, and other important facts in their life-histories.

2. The methods, extent and history of the fisheries, the kinds of apparatus used, the manner of using each and the species taken in each; the manner of caring for, and disposing of, the catch; the statistics of the fisheries, value of each kind of apparatus; number and nationality of people engaged in fishing; quantity an value of each species caught, and prices paid the fisherman, also the wholesale and retail prices; and changes in the methods of the fisheries since the coming of Americans, Europeans and Asiatics to the islands will be investigated.

3. The development of proper and just fishery laws will receive special consideration; the history of fishery legislation, including the system of tabu, and the present laws and methods with reference to each species covered by any law, special or general, and the possibility of trade in fishery products with the United States, improvement in the methods of the fisheries, and the methods of handling and marketing the fish will receive careful consideration. Attention will also be given to the possibility of fish-cultural operations with reference to such species as may be in danger of extinction or serious diminution.

Drs. Jordan and Evermann will sail for Honolulu May 30th and remain until September, when they will return to America and submit a preliminary report to Commissioner Bowers. Subsequently, they will return to Honolulu with the *Albatross* and make a study of the deep-water fauna of the islands.

The other members of the present expedition will be Dr. O. P. Jenkins, of Stanford University, Messrs. E. L. Goldsborough and John N. Cobb, of the United States Fish Commission, and Messrs. A. H. Baldwin and C. B. Hudson, who will paint in life colors the more important food-fishes of the islands. Messrs. Hudson and Baldwin are the artists who made the very accurate and beautiful colored drawings reproduced in Dr. Evermann's recent book on the Fishes and Fisheries of Porto Rico, of which Congress ordered the printing of an extra edition of 7,500 copies. It is expected that the Hawaiian report will be even more handsomely illustrated than is the report on Porto Rican fishes.

4. Mr. William H. Ashmead, Assistant Curator, Division of Insects, U. S. National Museum, will also accompany the expedition, and will make special efforts toward increasing our knowledge of the insect fauna of the archipelago.

THE BRITISH ANTARCTIC EXPEDITION.

Dr. J. W. Gregory, who was appointed scientific leader of the British Antarctic Expedition and as such recently contributed to *Nature* a plan of the scientific work, has now stated that he cannot accept service under the regulations laid down. This resignation, for so it has been regarded by the committee, is a very severe blow to the prospects of the expedition, or at least to the scientific results that might have been expected. Some, perhaps, prophesied failure when they saw the attempt that was made from the first to place the expedition under admiralty control and naval discipline. Friction and consequent heat became inevitable when the committee proceeded to appoint two leaders—a naval and a scientific—without defining their powers from the outset. It is well known that the meetings of this committee have been a series of fights between the geographers and naval men as opposed to the purely scientific men; and Dr. Gregory has over and over again been on the point of resigning. We understand that the ultimate dispute was over the question of landing, which Dr. Gregory wished to have fixed as a main object of the expedition, and not left entirely to the discretion of an unscientific commander. But the actual cause of rupture is immaterial. The position, thanks to the naval manoeuvres, has always been an impossible one for the scientific men While Dr. Gregory's absence in Australia has placed him at a disadvantage. Sir Clements Markham may be congratulated; but the committee will have a difficulty in finding a head for the scientific staff with half the competence of Dr. Gregory. The only satisfactory feature of the affair is that there has been no unpleasantness between members of the scientific staff, though doubtless some of them would be glad to follow Dr. Gregory's example.

SCIENTIFIC NOTES AND NEWS.

Dr. Frederick Peterson, of Columbia University, has been appointed by Governor Odell the medical member of the State Lunacy Commission. Dr. Peterson's appointment at the present time is especially fortunate, owing to the complications in connection with the State Pathological Institute, which will doubtless be settled with regard to the best interests of science and the care of the insane in the State hospitals.

At a meeting of convocation on April 20th, McGill University conferred on Dr. Robert Bell, of the Geological Survey of Canada, the degree of Doctor of Science.

Dr. Jacob Eriksson, professor of plant physiology at the Agricultural Station, Stockholm, has been elected a member of the Stockholm Academy of Sciences.

Dr. Ernst Koken, professor of mineralogy and geology in the University at Tübingen, has been elected a corresponding member of the Geological Society of London.

The Geographical Society of Paris has awarded the Henri Duveyrier gold medal to Dr. Cureau and the Alexandre Boutroue silver medal to Dr. F. Weisgerber.

Cambridge University has conferred the degree of D.Sc. upon Professor A. H. Church, F.R.S., in recognition of his contributions to chemical and mineralogical science.

A. S. Hitchcock, of the Kansas Agricultural Station, has been appointed assistant agrostologist in the United States Department of Agriculture.

Dr. Clayton H. Sharp, instructor in physics at Cornell University, has resigned this position to become testing officer of the Lamp Testing Bureau. This bureau is a corporation organized under the laws of the State of New York, which has hitherto been engaged solely in testing incandescent lamps, but which is in the near future to establish a laboratory in New York City for testing and standardizing not only electric lamps, but also all kinds of electrical apparatus and instruments.

DR. WILLIAM H. SQUIRES, who has spent the past two years in study at the University of Munich, is expected to return in September to Hamilton College, where he has been appointed professor of psychology, logic and pedagogics.

AT the general meeting of the Royal Institution, London, on May 6th, the following vice-presidents were nominated for the ensuing season: Sir Frederick Bramwell, Sir James Stirling, Sir William Abney, Lord Kelvin, Mr. George Matthey and Mr. Frank McClean.

DR. ERNST GILG has been appointed curator of the Botanical Museum of the University of Berlin.

DR. L. O. HOWARD, chief of the Division of Entomology, U. S. Department of Agriculture, lectured at Orange, N. J., on May 16th, giving practical information in regard to the relations of mosquitoes to disease and directions for exterminating the insects.

MR. ELWOOD MEAD, expert in charge of irrigation experiments, U. S. Department of Agriculture, Washington, D. C., is in Cambridge for the month of May giving a course of lectures on irrigation to the engineering students of Lawrence Scientific School of Harvard University.

WE learn from the *British Medical Journal* that the Croonian Lectures before the Royal College of Physicians of London will be given by Professor W. D. Halliburton, F.R.S., on June 11th, 13th, 18th, and 20th. The subject of the course is 'The Chemical Side of Nervous Activity.' The Goulstonian Lectures, 'On Certain Mental States associated with Visceral Disease in the Sane,' postponed owing to the illness of Dr. Head, will be given on June 25th and 27th, and July 2d.

THE sum which is being raised for the purposes (*a*) of placing a bust, relief or portrait in the Bodleian Library, and (*b*) of forming a fund to be called the 'Max Müller Memorial Fund,' which may be held by Oxford University in trust for the promotion of learning and research in all matters relating to the history and archeology, the languages, literatures and religion of ancient India, now amounts, as we learn from the London *Times*, to about £1,750. The subscribers include the King, the German Emperor, the King of Sweden and Norway, Prince Christian, the Duchess of Albany, the Prime Minister, the Crown Prince of Siam, a number of Indian princes, and a great many well known people in Oxford and the country generally. It is hoped eventually to raise £2,500, so that at least £2,000 may be available for the 'Memorial Fund.' Professor A. A. Macdonell is honorary secretary to the movement, and Mr. C. Grant Robertson, All Souls College, Oxford, honorary treasurer.

PROFESSOR H. G. VAN DE SANDE BAKHUYZEN, the Secretary of the International Geodetic Association, has sent from London an announcement calling attention to the death of Dr. Adolphe Hirsch, director of the Observatory at Neuchâtel. Professor Hirsch was a member of the Association, since the first meeting in Berlin in 1866, and was the following year elected secretary. This office he held for thirty-five years, having resigned it at the meeting at Paris last year, owing to the condition of his health.

DR. CHARLES RICE, chairman of the revision committee of the United States Pharmacopoeia, died in New York City on May 15th. Dr. Rice was born in Munich in 1841. He received a very thorough education in Vienna, Munich and Passau, acquiring a mastery of several oriental languages, the classics and the modern tongues. He was an accomplished linguist and was recognized as an authority on questions of philology and etymology. Dr. Rice came to America in 1862 and, during the war, served in the navy as surgeon's steward. After his discharge from service he entered the Department of Public Charities and Corrections, of New York City, and has been the chemist of that department and superintendent of its drug department for many years. He has served as chairman of the revision committee of the United States Pharmacopoeia since 1880, and, in the language of Dr. Horatio C. Wood, President of the last Pharmacopoeial Convention in May, 1900, 'has made it in its scientific accuracy, in its general usefulness and in the efficiency and elegance of its resulting preparations, the peer of the best.'

David Shepard Holman, the inventor of accessories to the microscope and other devices, died on May 13th. He was for a long time actuary of the Franklin Institute, Philadelphia, for which he frequently lectured. Recently he has been an expert in the laboratory of the Atlantic Refining Company.

There will be a civil service examination on June 3d for the position of soil analyst in the Bureau of Soils, Department of Agriculture, at a salary of $750. The subjects of the examination are physical chemistry, soil analysis, soil physics and German.

The Godard and Bertillon prizes of the Anthropological Society of Paris will be awarded during the present year. The Godard prize (500 fr.) will be given for the best memoir on an anthropological subject, and the Bertillon prize (500 fr.) for the best memoir on a subject concerned with demography. Manuscripts or publications in competition for the prizes should be in the hands of the secretary of the Anthropological Society (15 rue de l'Ecole de Médicine, Paris) not later than July 11, 1901.

The Federation of the Agricultural Unions of Italy has decided to offer an international prize of the value of about $200 to be awarded to the person who discovers and makes public the best method for obtaining exact and constant results in the determination of the fineness of the flowers of sulphur and of mixtures of sulphur and copper sulphate. Competitors must send in their papers in a sealed envelope to the head office of the Federation (Ufficio direttivo della Federazione Italiana dei Consorzi agrari, Piacenza, Italy) before March 1, 1902. The papers will be examined by a special commission to be named by the Reale Accademia dei Lincei, Rome.

The extensive herbarium of the late Dr. T. Bernard Brinton has been presented to the Botanical Garden of the University of Pennsylvania.

Cablegrams to the daily papers report that the observations of the solar eclipse on the 17th instant were only partially successful, the sun being more or less obscured by clouds. The corona was of the expected minimum type, being more diffuse and less definite than in the case of the eclipse a year ago.

A telegram was received on May 16th, at the Harvard College Observatory, from Professor R. H. Tucker, Lick Observatory, stating that Comet Queenstown was observed by Dr. R. G. Aitken, May $15^d.6668$ Greenwich Mean Time in R. A. $5^h\ 38^m\ 25^s.8$ and Dec. $+ 3° \ 52' \ 12''$.

New York University's Hall of Fame will be dedicated on May 30th with elaborate ceremonies. The different tablets will be unveiled and addresses will be made. Professor B. L. Robinson, of Harvard University, and Professor B. D. Halsted, of Rutgers College, will unveil the tablet to Asa Gray, and Professor R. H. Thurston the tablet to Eli Whitney. The tablet to S. F. B. Morse has been assigned to the American Institute of Electrical Engineers, to be represented by Carl Hering, president, who will associate with him the president-elect. The tablet to Robert Fulton will be unveiled by James R. Croes, president, and Charles Warren Hunt, secretary, of the American Society of Civil Engineers. It has not yet been announced who will unveil the tablet to the memory of Audubon.

According to a preliminary program, issued by the American Society of Electrical Engineers, the summer meeting of the Institute will open on August 14th, when a formal reception will be held in New York City. It is planned to spend the two following days in visits to the electrical works in the neighborhood, and on Sunday to go to Albany, traveling in part by boat up the Hudson River. On August 19th, the works of the General Electrical Company at Schenectady will be visited, after which the party will proceed by special train to Buffalo. It is proposed to hold the general meeting at Buffalo on Tuesday morning and to visit the Exposition in the afternoon. On the three following days the morning sessions will be devoted to the reading and discussion of papers. August 22d will, if possible, be devoted to an excursion to Niagara Falls, where the electrical works will be visited. The various sub-stations at Buffalo will also be open to members. The closing meeting will probably be held on August 24th.

THE Royal Society of Canada held its spring meeting at Ottawa, beginning with the meeting of the council on May 26th. We hope to publish some account of the proceedings in a subsequent issue.

THE second meeting of the Russian Surgical Congress will be held at Moscow in January, 1902 (9th, 10th and 11th), under the presidency of Professor A. Bobroff.

THE Liverpool School of Tropical Medicine will send to West Africa, during the present month, an expedition against the *Anopheles* mosquito under Major Ronald Ross. A leading Glasgow citizen has placed at the disposal of the school and Major Ross a sum of money sufficient to defray the expenses of one year's trial in some malarious city. A staff of workers with all necessary appliances will therefore be maintained at a selected West African city, attacking mosquitoes in the city and environs.

A SMALL collection of pictures, illustrative of the people of the Senegal and French Soudan and their customs, painted by M. Joseph de la Nézière, is on exhibit at the rooms of the Royal Geographical Society, London.

A CORRESPONDENT to the London *Times* writes that the meeting of the Royal Society on May 9th was strictly private, the usual admission of a certain number of the general public being suspended. The Society was engaged in discussing the report of a committee appointed to consider some means of establishing a British academy of larger scope than the existing Royal Society, which should represent philosophico-historical branches of study, as well as the more exact sciences to which the Royal Society has in the main, if not altogether, confined itself. The idea sprang out of the fact that the Royal Society has taken an active part in the formation of an international association of the principal scientific and literary academies of the world. This association is divided into two sections—scientific and literary. While the Royal Society can represent Great Britain in the scientific section, it seems that it has no organization eligible to represent Great Britain in the other section, which includes history, antiquities, philosophy, economics and so forth—subjects which may be studied in a scientific spirit, but do not lend themselves to experiment and exact verification. The discussion, like the report upon which it was based, was inconclusive. The Royal Society shrinks from taking an active part in the formation of another academy dealing with the subjects in question, which might in various ways, and especially in its demands upon the public purse, become a serious rival to the Royal Society itself. The only alternative is that the Royal Society should enlarge itself in one way or another so as to include the studies classed on the Continent as literary. But, though more than one way of doing this has been suggested, the difficulties in every case are obvious and great. So far as can be gathered, the weight of opinion in the Royal Society is against any attempt to meet what, after all, is a rather visionary demand. If the disadvantages flowing from the want of an academy are as serious as they are represented, it is obviously the students of the subjects in question who ought to supply the need they feel. The Royal Society has a vast field for its energies in connection with its own proper work.

UNIVERSITY AND EDUCATIONAL NEWS.

PRESIDENT J. H. BARROWS has announced that of the $300,000 necessary to secure the conditional gift of $200,000, offered by Mr. John D. Rockefeller to Oberlin College, the sum of $150,000 has already been promised.

A GIFT of $25,000 to the Yale Bicentennial Fund has been made by William C. Whitney, of New York City.

MRS. S. H. CAMP, of Hartford, Conn., has given $10,000 to the Philosophical Department of Yale University for a departmental library.

IN 1897 Governor Roswell P. Flower presented to Cornell University $5,000 to found a library for the use of the New York State Veterinary College; and Mrs. Flower has now given $10,000 to endow this library. With the books and periodicals obtained with the original gift, and those which can be obtained from year to year by the income of the endowment fund, it is believed that the Flower Library will become one of the best equipped libraries of comparative medicine in the world, and be

of great service to the live stock interests, and therefore an important factor in the prosperity of the State.

Mr. William Johnson, a Liverpool shipowner, has established two fellowships in physiology and pathology, in University College, Liverpool, one open to members of British colonial universities and medical colleges; the other to foreign students and intended especially for students in the United States. The provisional regulation governing the latter fellowship are as follows:

1. This fellowship has been founded to commemorate the late John W. Garrett, of Baltimore, United States, and shall be called 'The John W. Garrett International Fellowship in Pathology and Physiology.' The value of the fellowship shall be £100 a year.

2. The fellowship shall be open to members of universities and medical schools in the United States, without, however, absolutely precluding members of other foreign schools.

3. The fellow shall be elected by the faculty, on the nomination of the professors of pathology and physiology.

4. The fellow shall be elected for one year and shall be eligible for re-election.

5. The fellow shall devote himself to research in physiology or pathology and bacteriology under the direction of the professors of physiology and pathology. He shall undertake no work which shall in any way interfere with these duties.

6. The work shall be done in the Thompson-Yates laboratories of University College, Liverpool, but, by special permission from the faculty, the fellow may be allowed to follow his investigations elsewhere.

7. The expenses of the research shall be met out of the funds of the laboratory under the direction of the professors of physiology and pathology.

The committee of the National Educational Association on a National University met at Columbia University May 23rd. It was expected that the committee would then adopt its final report. This will doubtless be on the lines of the preliminary report that we published some time ago. A national university will not be approved, but plans for utilizing the scientific opportunities at Washington will doubtless be proposed.

Dr. John E. Clark, James E. English professor of mathematics at Yale University, has retired on account of ill health. He has been made professor emeritus, and Dr. Percy F. Smith, associate professor of mathematics, has been appointed as his successor. In the Sheffield Scientific School of the same university, Dr. Earle Raymond Hendrick, of Ann Arbor, has been appointed instructor in mathematics, and Mr. Edwin Hoyt Lockwood has been promoted to an assistant professorship of mechanical engineering.

Dr. Truman H. Safford, professor of astronomy at Williams College, has retired from the active duties of his professorship.

At Harvard University Dr. Jay Backus Woodworth has been promoted to an assistant professorship of geology, and James K. Whittemore has been made instructor in mathematics.

Dr. Joshua W. Beede, B. S. (Washburn College) and Ph.D. (Kansas) has been elected instructor in geology in Indiana University.

The following fellowships in the sciences have been awarded at Cornell University: The McGraw fellowship, Augustus Valentine Saph, B.S., M.S. (California), in civil engineering; the Schuyler fellowship, Küchi Miyake, Imperial University of Tokyo, in botany; the Goldwin Smith fellowship, Lee Barker Walton, Ph.B. (Cornell), A.M. (Brown), in entomology; the President White fellowship, Floyd Roe Watson, B.S. (California), in physics; the Erastus Brooks fellowship, John Wesley Young, Ph.B. (Ohio State University), in mathematics; Susan Linn Sage fellowships in philosophy and ethics, John Wallace Baird, A.B. (Toronto), Georgia Benedict, A.B. (Wells), and Henry Wilkes Wright, Ph.B. (Cornell).

Dr. J. N. Langley, reader in histology at Cambridge University, has been appointed, for a period of two years, as deputy for Sir Michael Foster, M.P.

Mr. W. E. Thrift, fellow of Trinity College, Dublin, has been elected Erasmus Smith professor of natural and experimental philosophy, in succession to the late Professor Fitzgerald.

Dr. B. Němec, docent in botany at the Bohemian University at Prague, has been appointed director of the Institute for Plant Physiology.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

*THE SEA BOTTOM—ITS PHYSICAL CONDITIONS AND ITS FAUNA.**

IT is hard to realize the fact that, up to a comparatively recent date, nearly three-fifths of the actual solid surface of the earth was absolutely a 'terra incognita,' a region as unknown as the poles, and as full of mystery as the center of the earth. Yet, if it be true that the sea covers nearly three-fifths of the surface of the earth, it is also true that its bottom, which is the actual solid surface of the globe, was, up to the middle of the century just ended, absolutely unexplored, excepting a very narrow strip around the edges.

For the purpose of our study this evening, we may define the deep sea as all that is deep enough to exclude sunlight and vegetable life in appreciable quantities from the bottom. We may safely assume that this limit is at a depth of about 150 fathoms. Sensitive photographic plates are said to be unaffected beyond the depth of about 125 fathoms clear water.

It thus becomes apparent that we shall have to include as deep sea almost all the area covered by the oceans of the world, there being but an inconsiderable strip around the edges that is within the 150-fathom line. The average depth is very

* Lecture delivered before the Nebraska Chapter of the Society of the Sigma Xi, February 14, 1901, by Professor C. C. Nutting, of the State University of Iowa.

much greater than that. Indeed, we now know that more than one half of the actual surface of the globe is over two miles beneath the surface of the water, and that about seven million square miles are buried under more than 3,000 fathoms of ocean.

Still greater depths are by no means uncommon. The *Challenger* sounded at a depth of 4,561 fathoms in the North Atlantic, and Uncle Samuel, not to be outdone by his British brother, very recently found a depth of 5,200 fathoms near the lately acquired Island of Guam. This is, so far as we know, the deepest abyss of the ocean, being 31,200 feet, or nearly six miles. Into such a depth the highest terrestrial mountain could be plunged without any resultant peril to navigation, as there would still be some 2,000 feet above the highest crest.

As already indicated, this vast realm of darkness was unexplored previous to about the middle of the nineteenth century. The pioneer explorer of the sea bottom was a Norwegian zoologist, Michael Sars. Then followed several expeditions under the patronage of the British Government, culminating in the *Challenger* voyage, the results of which stand to-day as a peerless example of a wise and liberal policy in the encouragement of scientific research.

The United States has come well to the front in deep-sea investigation, and now owns the best equipped vessel for this work in the world. I refer to the *Albatross*, of which we shall hear more later. Americans may well take pride in remembering that the oceanic basins near our eastern and southern coasts are more thoroughly explored than any other parts of the sea bottom.

Investigations of this nature have been attended with almost insuperable difficulties, necessitating the devising of a number of entirely novel instruments and machines for this particular work. Several of the most successful of these were invented by American naval officers, of whom Captain Sigsbee, of the ill-fated *Maine*, has been the most prominent. Our knowledge of the sea bottom has been gained mainly by the use of the following appliances:

1. The *sounding machine*. To drop a weight attached to a line to the bottom of the sea would seem to be as simple a proposition as could well be devised. As a matter of fact, however, its successful accomplishment has taxed the inventive genius of the most accomplished engineers. Sigsbee's sounding machine, with detachable weight and piano-wire line has proved the best device for obtaining accurate soundings and adequate samples of the bottom. This and the other instruments about to be mentioned will be illustrated and briefly explained later.

2. The *thermometer*. Temperature observations have been of the utmost importance in determining the physical conditions of the deep sea, and various kinds of thermometers have been devised to withstand the enormous pressure and register the maximum and minimum heat. Not infrequently these expensive instruments have been brought to the surface with their bulbs crushed to powder by the terrific pressure of the abyss.

3. The *water bottle*. Not only must depth and temperature be ascertained, but the actual composition and condensation of the water must be found by means of samples that can be secured free from admixture with sea water of other depths. Here also the genius of Captain Sigsbee was equal to the emergency, and the 'Sigsbee water bottle' has proved itself a convenient and efficient instrument, being so constructed that it will take a sample of water at any given depth and then automatically seal itself and remain hermetically closed until opened by hand.

4. The *dredge*, for scraping over the bottom and securing specimens of the animal life of the deep.

5. The *trawl.* A large bag-like net, useful on soft bottoms, over which it will pass without digging into the soil. It has a larger mouth and greater capacity than the dredge.

6. The *tangle-bar*, to sweep over rocky bottoms on which the other instruments would foul and often be lost. It is in effect a series of long swabs that will entangle in its hempen fibers almost anything from coral rock to fishes. It is probably the most effective all-around instrument for general work, and the least likely to fail or be lost. We found it invaluable in West Indian waters of moderate depths.

With these six instruments, then, the sea bottom has been sounded, its temperature taken, samples of both water and bottom secured and specimens of its animal life brought to light, both figuratively and literally. As yet this vast territory has been but scratched here and there. We can speak with confidence, however, concerning the general physical conditions, and we are acquainted with thousands of the strange and bizarre creatures that constitute its fauna.

Regarding the physical features of this under world, the following points are worth consideration :

The temperature is uniformly low, probably below 40°, except in enclosed seas in tropical regions such as the Red Sea. In many places the temperature is actually below the freezing point of fresh water. I well remember the surprise felt by the members of a dredging party one excessively hot day off Havana, indeed within sight of the now famous Morro Castle, when they plunged their hands in a mass of mud brought up in the dredge and found it so cold as to make them fairly ache. Of course the cold water reaches the surface in high latitudes, but it covers the entire floor of the ocean at depths over 150 fathoms. This practical uniformity of temperature over the entire submarine surface of the globe plays an important part in the well-known wide distribution of deep-sea species.

The general impression that high temperature is more favorable than a low one for the best development of animal life is certainly not true of marine animals in general, whatever may be the facts concerning some special groups. If other conditions are favorable, a luxuriant fauna will be developed in any temperature short of the freezing point of salt water. But a *change* of temperature, if a sudden one, is sometimes the cause of oceanic tragedies of frightful extent, a fact illustrated by the following example :

The tile-fish is a deep-water species, living upon the bottom on what is known as the Gulf Stream slope, off the New England coast. Here the water is normally comparatively warm, coming as it does from the superheated region of the Gulf of Mexico.

During a series of unusually severe gales in the summer of 1882 this mass of water was pushed aside, as it were, and replaced by the colder water. As a result, millions and millions of these fish were killed, and their dead bodies literally covered the surface of the sea for hundreds of square miles. So great was the slaughter that for years it was feared that the tile-fish were exterminated. Fortunately, however, the region has been recolonized, probably from the south, and numerous tile-fish have been taken during the past two seasons.

Probably the most remarkable of the conditions of deep-sea life is the enormous pressure, which varies of course with the depth. At the average depth (2,000 fathoms) the pressure is about two tons to the square inch of surface, and at 4,000 fathoms each square inch of surface is subject to a pressure of about four tons. This fact led the earlier physicists to maintain that or-

ganic life was impossible in the great depths. It has been proved, however, that animals of all classes, except the higher vertebrates, have been dredged from even the deepest abysses of the ocean.

The great pressure to which they have been subjected has a curious effect on the deep-sea fishes when they are brought to the surface. Under these circumstances, being released from the accustomed pressure, they fall to pieces, as it were. The eyes bulge out, the swim-bladder protrudes from the mouth, the scales fall off and the flesh comes off in patches, the tissues being remarkably loose. Now these fishes, disreputable as they appear when brought to the surface, were doubtless respectable enough in their proper habitat, and, like some other creatures, become loose and far from correct in appearance when away from home, simply because the pressure is less.

In the depths they are doubtless no more conscious of the pressure of four or five tons to the inch than we are of the fifteen pounds of atmospheric pressure under which we live and move and have our being.

Owing to the incompressible nature of water it does not differ appreciably in density at different depths, and any object that will sink at the surface will continue to sink until the bottom is reached, however deep that may be.

The presence of oxygen is of course of vital import to animal life in the deep sea as elsewhere, and it was long deemed impossible that any considerable quantity of oxygen could exist at great depths. It has been found, however, that there is no lack of this vital element either near the surface or in the deepest soundings. Sir Wyville Thomson, the naturalist in charge of the *Challenger*, made a very careful study of oceanic currents and found that the cold water of the polar regions, charged with oxygen derived from the superincumbent atmosphere, creeps along the bottom towards the equator from both poles, thus carrying oxygenated water over the vast area of sea bottom throughout the oceanic floor of the world. It also appears that the general trend of the surface water is toward the poles. This great scheme of circulation involves the general rise of the cold, deep water of the equatorial regions toward the surface, where it receives a fresh supply of heat and oxygen, carries much of the heat to northern regions and, after giving it off, returns southward again in the form of oxygen-bearing undercurrents. To my mind there are few terrestrial phenomena more impressive than this majestic cosmic current with circulation slow and sure, carrying with it the tremendous potency of life to and throughout the uttermost depths of the sea. Were it not for this world circulation, it is altogether probable that the ocean would in time become too foul to sustain animal life, at least in its higher manifestations, and the sea, the mother of life, would itself be dead.

The condition of the physical environment of the life of the ocean depths that strikes one as the most forbidding is the practical absence of sunlight from the enormous area included in the deep sea. As already stated, actual experiment has shown that photographic plates are not affected at a depth of over 125 fathoms in clear water, and light, which can not be detected by the exceedingly delicate eye of the camera, is surely invisible to any organ of vision constructed on the same general plan as the human eye. There is practical agreement among all the authorities, save one, that I have been able to consult that the rays of the sun do not penetrate perceptibly below the 200-fathom line at the farthest. Professor Verrill is the exception referred to, and he has advanced the theory that a pale green light penetrates even to the deepest waters. He thinks that all the other colors of the spec-

trum are removed from the sun's rays by absorption, leaving the green rays only. He comes to this conclusion from a study of the colors of the animals of the deep sea, which demonstrate, in his opinion, the presence of light of some kind. He apparently assumes that this light comes from the sun, and resorts to the explanation just referred to to prove its presence in the oceanic depths.

We shall see presently, I hope, that it is not necessary to assume the presence of sunlight at the sea bottom in order to meet the demands for light revealed by a study of the coloration of its inhabitants.

The bottom waters, then, are almost freezing cold, subject to tremendous pressure, moved by slow currents creeping from pole to equator, supplied with sufficient oxygen to sustain animal life, and devoid of sunlight. Could a more uncomfortable and altogether forbidding habitat be conceived of for an animal population? Certainly not, from our standpoint. But it must be remembered that we are neither fishes, nor mollusks, nor jelly-fishes; and that everything depends upon being used to environment. A practical application of this fact would result in the saving of a lot of otherwise wasted sympathy in human as well as zoological affairs.

Let us now turn our attention briefly to the topography of the sea bottom. It may be said, in general, that there are few abrupt changes of level; that the ascents and descents are gradual, and that there are few areas which, if laid bare, would present anything like the broken contours of a mountainous region. In areas adjacent to continents and archipelagoes the topography is often considerably broken, but away from the land masses the sea bottom is, ordinarily, as level as a western prairie. Few, if any, bare rocks are to be found, except where recent submarine volcanic explosions have torn up the subjacent strata, or the cooling lava has encrusted the bottom. Practically the entire sea bottom is covered to an unknown depth by a soil that varies with the depth in a definitely determinate manner. This soil, like that of the upper world, is organic in its origin, being composed in large proportion of the remains of a few species of very widespread forms, individually minute, but collectively of stupendous bulk. These animals belong almost exclusively to the Protozoa, or one-celled forms, and largely to the class Rhizopoda. They are of immeasurable importance from a biological standpoint, furnishing, as they do, the food basis for all marine life. As a type of these organisms *Globigerina bulloides* stands forth preeminent, a form of exquisite beauty of structure, being like a series of minute chalky spheres, exquisitely sculptured, from which radiate many and almost infinitely slender and delicate spicules which serve to support the living animal on the water, which, in places, is rendered of a reddish color by the hosts of these Rhizopods. It has fallen to the lot of but few naturalists to examine these creatures in a living and perfect state, as the slightest touch will rob them of their beautiful spicules and cause the living protoplasm to retreat within the hollows of the spheres. Minute and fragile as they are, the skeletons of these animals, and of others equally small, cover at the present time many millions of miles of the sea bottom, and in times past were the main element in building up the mighty chalk deposits of the world.

If we were to run a line of soundings from the continent of North America eastward to the mid-Atlantic, we should find that the bottom could be easily divided into three regions on the basis of the soil, as I have termed it, covering everywhere the actual rocks. For the first few miles the bottom would be covered with débris of many kinds from the adjacent land.

Rocks and gravel and sand, together with mud and silt, if near the mouth of a river, would succeed each other. The surface might be broken into rocky pinnacles and caverns, water-worn in fantastic shapes in the region of a rocky coast; or, if the coast be low and sandy, there might be a perfectly even and gradual slope from the shore to a depth of 150 or perhaps 200 fathoms.

This slope, covered with continental débris, is known as the 'continental slope,' and is very apt to be more uneven and broken in its topography and to support a more luxuriant fauna than any other part of the sea bottom. Beyond the continental slope the descent becomes more abrupt, leading down to a depth of 1,500 fathoms or more.

The bottom samples will now take on a distinctly different character, being composed of a grayish mud. If a little of this is examined under a microscope, it will be found to be made up of countless millions of the tests of *Globigerina* and other unicellular animals. Not a single thimbleful of this mud is devoid of its hosts of skeletons. This wet and slimy bottom soil is known the world over as '*Globigerina ooze*,' and it covers the ocean floor for many millions of square miles.

In a line of dredgings made by the *Challenger* from Teneriffe to Sombrero, taking in the widest part of the Atlantic, about 710 miles were found to be covered with *Globigerina ooze*, which was found in characteristic form from a depth of 1,525 to one of 2,220 fathoms. Beyond the latter depth the bottom was of a distinctly different character, changing to an extremely fine-grained reddish-brown mud, oily to the feel. It is so finely divided that it takes many hours to settle when mixed in a glass of water. This is known among oceanographers as 'red clay,' and is supposed to be derived almost exclusively from two widely different sources:

First: The residue of the innumerable hosts of pelagic animals remaining after their calcareous skeletons have been dissolved in sea water.

Second: Pumice and volcanic dust, either from submarine upheavals or from the atmosphere. From either or both of these sources the accumulation of the red clay must have been almost infinitely slow, taking perhaps millions of years to deposit a few inches in thickness on the ocean floor. This sort of bottom deposit is of much greater extent than either of the others, and is supposed to cover about one-half of the sea bottom, an area greater than the total land surface of the globe.

It can easily be conceived that no stretch of the land surface can compare in dreary monotony with those awful solitudes of the *Globigerina ooze* and the red clay. Even if illuminated by the sun's rays, they would be forbidding and dreary beyond compare.

Resting immediately upon the bottom already described is a layer of unknown depth of a flocculent material that is of incalculable importance in our discussion. When first discovered this substance, owing to its strange movements in alcohol, was supposed to be alive, and was described by Huxley under the name of *Bathybius*, and considered as a sort of primordial organism from which the entire life of the globe may have originated. *Bathybius*, however, was doomed to be regarded as one of the colossal jokes of science, and a thorn in the flesh of its describers.

But, after all, it is now thought that the much-derided *Bathybius* is fully as important as claimed by Huxley, but in another way. It is not alive, to be sure, but still it is organic, consisting of the partially decomposed remains of the pelagic animals, such as *Globigerina* and other forms already referred to. These have died near the surface, and have gradually but surely found their way to the bottom, where they remain

partially suspended in a layer of soup-like consistency and character. *Bathybius*, then, is now no longer known as *Bathybius*, but as '*bottom broth*,' an exceedingly suggestive term, and it is supposed to be the inexhaustible supply of nourishment, the basal food store-house of the innumerable creatures that live and move, or simply live without movement, at or near the bottom of the sea, the simplest and most helpless of which have but to open their mouths, if mouths they have, and suck in bottom broth as the infant does pap. If Old Ocean is really, as so often asserted, the mother of terrestrial life, then bottom broth can truly be regarded as a sort of mother's milk, for the nourishing of her weak and helpless offspring.

Having discussed the physical conditions under which the animals of the deep sea exist, let us now turn our attention to the animals themselves.

Personally, I may say that nothing regarding the animals dredged from deep water has impressed me more than their colors. It seems an unquestionable fact that they live in practical darkness, and one naturally expects them to be colorless.

Now we know of a considerable number of animal forms that certainly do live in utter darkness in the subterranean waters of extensive caves, such as Mammoth or Wyandotte Caves. These animals have been very carefully studied, especially by my friend Dr. Eigenmann, of Indiana University, who tells me that true cave species are always practically blind and colorless. But the animals brought up from the deep waters of the ocean are often very brightly and conspicuously colored.

The question at once arises: What is the significance of these colors? Are they merely fortuitous, or have they a meaning that can be deciphered, giving a clue that may lead to a further understanding of the mysterious realm beneath the waters? It is my purpose this evening to attempt to answer these questions, but before doing so let us examine briefly the main facts regarding the colors of abyssal animals. We will call as witnesses some of the naturalists of the widest experience in the science of thalossography, and supplement this evidence by facts of personal observation.

Professor Mosely, of the *Challenger* staff, says: "Peculiar coloring matter giving absorption spectra has now been found to exist in all the seven groups of the animal kingdom. The Echinodermata and Cœlenterata appear to be the groups which are most prolific in such coloring matter. Pentocrinin and antodonin seem to be diffused in immense quantities throughout the tissues of the crinoids in which they occur and the Echinoderms generally seem to be characterized by the presence of evenly diffused and abundant and readily soluble pigments." Again, he says: "The same coloring matters exist in the deep-sea animals which are found in shallow water forms."

Alexander Agassiz, than whom no living man has had more experience in deep sea work, says: "There are many vividly colored bathyssal animals belonging to all the classes of the animal kingdom and possessing nearly all the hues found in living types in littoral waters. * * * There is apparently in the abysses of the sea the same adaptation to the surroundings as upon the littoral zone. We meet with highly colored ophiurans within masses of sponges themselves brilliantly colored at a depth of more than 150 fathoms. * * * While we recognize the predominance of tints of white, pink, red, scarlet, orange, violet, purple, green, yellow and allied colors in deep water types, the variety of coloring among them is quite as striking as that of better known marine animals. * * * There is as great a diversity in color in the reds, oranges, greens, yellows, and

scarlets of the deep-water starfishes and ophiurans, as there is in those of our rocky and sandy shores. * * * Among the abyssal invertebrates living in commensalism the adaptation to surroundings is fully as marked as in shallow waters. I may mention especially the many species of ophiurans attached to variously colored gorgonians, branching corals and stems of *Pentacrinus* scarcely to be distinguished from the part to which they cling, so completely has their pattern of coloration become identified with it. There is a similar agreement in coloration in annelids when commensal upon starfishes, mollusks, actiniæ or sponges, and with Crustacea and actiniæ parasitic upon gorgonians, corals, or mollusks. The number of crustaceans * * * colored a brilliant scarlet is quite large."

Professor Verrill, of Yale University, in his report on the Ophiurans, collected by the Bahama expedition from the University of Iowa, repeatedly calls attention to the agreement in color between these animals and the forms upon which they grow.

My own observations fully confirm those of the naturalists just quoted. Among the crustaceans were many species colored a bright scarlet, and one was an intense blue. The echinoderms were particularly striking in their coloration. Yellow and purple Comatulæ abounded in deep water near Havana. Serpent-stars were brown, white, yellow, red, purple and deep violet. A basket-fish, colored chocolate-brown and vivid orange, was abundant off the Florida Keys. There were sea urchins with crimson and white spines; another particularly gorgeous one had a test with alternating zones of chocolate and orange, and spines barred with carmine and white. The cœlenterates told the same story, but it is unnecessary to multiply further the evidence. Enough has been given for our purpose, which was to demonstrate the existence of bright colors in considerable quantities in the deep waters of the ocean, and we feel justified in making the following general statements regarding these colors:

1. The colors are often as brilliant as in shallow water.

2. The reds, orange, yellows, violet, purple, green and white predominate.

3. The colors when present are usually in solid masses in striking contrast, or else the whole animal is brilliantly colored. Fine patterns are very scarce, and nature seems to have used a large brush in adorning her children of the depths.

Now let us return to our question: What is the significance of these brilliant and varied colors?

I must confess to being a Darwinian of the strict constructionist school, and believe fully in the doctrine that no animal possesses any character, including color, that is not of use to the species to which it belongs, or has not been of use to the ancestors of that species. It is my conviction that if we knew all the circumstances surrounding the past history and present life of any animal, we could explain on the score of utility every character, using the word in the zoological sense, possessed by that species. And it is my purpose to use the coloration of deep-sea animals to illustrate this law.

In my opinion, the presence of all these colors can mean but one thing, and that is that there is light even in the deepest depths of the ocean. Or, to state the matter in another way, if we can prove the presence of light in considerable quantity at the bottom of the sea, the colors of its inhabitants become entirely explicable. We can then explain them as we do the colors of the animals of shallow waters, regarding the colors as protective, aggressive, alluring, attractive, directive, and so forth, as the case may be.

There is another line of evidence tending to prove the presence of light at the sea bottom, and this is the fact that most of the vertebrates inhabiting the depths have functional eyes, often more highly developed than in shallow water, and only exceptionally are the eyes aborted or absent. Dr. Alexander Agassiz has the following to say on this point:

"We should not forget, on the one hand, that blind Crustacea and other marine invertebrates without eyes, or with rudimentary organs of vision, have been dredged from a depth of less than 200 fathoms, and, on the other, that the fauna as a whole is not blind, as in caves, but that by far the majority of animals living at a depth of about 2,000 fathoms have eyes either like their allies of shallow water, or else rudimentary or sometimes very large, as in the huge eyes developed out of all proportion in some of the abyssal crustaceans and fishes."

And Professor Verrill says: "That light of some kind and in considerable amount actually exists at depths below 2,000 fathoms may be regarded as certain. This is shown by the presence of well-developed eyes in most of the fishes, all of the cephalopods, most of the decapod crustacea, and in some species of other groups. In many of these animals the eyes are relatively larger than in the allied shallow-water species."

In view of the almost uniformly blind condition of cave animals on the one hand, and of the well-tested Darwinian doctrine that useless structures, unless rudimentary, do not exist, on the other, I think we are justified in saying that a study of the coloration of the deep-sea animals, in connection with the general presence of functional eyes, is reasonable proof that light in appreciable quantities exists even at the greatest oceanic depths.

This being granted, we naturally turn to a consideration of the question: What is the nature of this abyssal light?

As already intimated, it is incredible that sunlight could penetrate in appreciable quantities to any such depth as 2,000 fathoms or over, or even to one-tenth of that depth, notwithstanding the theory advanced by Verrill, who seems to consider the presence of sunlight necessary to explain the facts of coloration. I think we are safe in assuming with Agassiz that at 200 fathoms the light from the sun is possibly that of a brilliant starlight night, and we are also justified in concluding that coloration would be useless in such a light. Did you ever notice how little of color can be seen even in the clearest moonlight night?

Sunlight being out of the question, is there evidence of any other light that would satisfy the conditions of coloration and organs of vision already referred to?

I have, on other occasions, sought to collect the evidence of the existence of abyssal light, and to determine its nature and function in the life economy of the deep sea. These efforts resulted in the belief that the light sought for is a phosphorescent light, and that it is adequate to explain the phenomena already discussed in connection with the colors of deep-sea animals.

This idea has been suggested before by several writers, notably by Andrew Murray, of the *Challenger*, but it has heretofore been only a suggestion which no one has taken the pains to seriously investigate. It will be of interest, therefore, to consider the extent to which phosphorescent life is characteristic of the deep sea.

For the purposes of the discussion we will divide the animals of the sea bottom into two classes, the free swimming and the fixed forms.

Considering the free swimming forms first, we find among the fishes several allied to *Lophius* and *Antennarius*, which are provided with a bait said to be luminous, which serves to attract the prey. Others are luminous along the lateral line in defi-

nite spots. The utility in this case is not certainly known, but two suggestions may be made, one to the effect that the light attracts the mate and thus serves the purpose of attractive coloration; the other that it attracts the prey and serves the purpose of alluring coloration.

A very large number of crustaceans are highly phosphorescent. Many of these have large eyes and are particularly active in movement and voracious in appetite. They feed on minute organisms for the most part, and it can hardly be doubted that they often use their phosphorescent powers for the purpose of illuminating their surroundings and revealing their prey. Here again it is probable that the strangely attractive power of light serves a definite purpose in the life economy of the animal.

Among the mollusca we have few instances, so far as I know, of phosphorescent organs. At the Detroit meeting of the American Association for the Advancement of Science, Professor William E. Hoyle, of England, read an exceedingly interesting paper on certain organs possessed by cephalopods secured by the *Challenger*. These organs were regarded as phosphorescent by Professor Hoyle, who described a highly specialized apparatus designed to reflect light from the phosphorescent bodies downward to the bottom over which the animal passed. In this case it appears that there is not only a light, but also a reflector, an efficient bull's-eye lantern for use in hunting through the abyssal darkness. Among the worms are many forms possessing a high degree of light-emitting power, which may be either attractive, alluring or directive in function, and thus of direct advantage to its possessors.

Most of the echinoderms, although not truly fixed, are not capable of rapid locomotion, and we are, therefore, not surprised to find few references to phosphorescence in connection with them. Perhaps the most active of this group are the serpent stars, and it is interesting that the only account that I find of phosphorescence in the echinoderms is Agassiz's description of a serpent star, which he says 'is exceedingly phosphorescent, emitting at the joints along the whole length of its arm a bright bluish-green light.'

Coming to the cœlenterates, we find many notable phosphorescent organisms. The ctenophores and medusæ comprise the greater part of the free swimming members of this subkingdom, and it is among these that we encounter amazing displays of the living light. The most brilliant exhibition of phosphorescence that I have seen was caused by immense numbers of ctenophores in Bahia Honda, Cuba. The animals kept in a compact body, producing a maze of intertwining circles of vivid light. The phosphorescence may help to keep them together, and thus serve the purpose of directive coloration among vertebrates and insects. This same explanation may apply to many of the phosphorescent medusæ. In the subtropical Atlantic hundreds of square miles of the surface are thickly strewn with a medusa, *Linerges mercurius*, which glows like a living coal at night.

In general, it may be said that phosphorescence is found abundantly in free swimming marine animals, and serves the same purpose as protective, aggressive and alluring coloration, and at the same time, in many cases, aids in securing prey by illuminating its retreat.

We come, now, to a consideration of the phosphorescence of the fixed animals of the deep sea and its uses. Most of the light-emitting organisms of this group belong to the subkingdom cœlenterata. The sea-pens are mentioned by several writers as being especially brilliant in their flashes of light. The gorgonians, or flexible corals, are often phosphorescent, and Agassiz says: "Species living beyond 100 fathoms may

dwell in total darkness and be illuminated at times merely by the movements of abyssal fishes through the forests of phosphorescent alcyonarians."

Many authors have noted the light-emitting powers of numerous hydroids. These occur in great quantities over certain areas of the sea bottom, and must add considerably to the sum total of deep-sea light.

It may, I think, be said that in general the fixed marine forms are not behind their free swimming allies in either the equality or the quantity of their light-emitting powers. The question now arises, of what value is the phosphorescence of fixed forms to its possessors? They have no eyes, and therefore can not be guided to their food by the light, neither can it aid them in finding mates nor in revealing the presence of enemies. Perhaps the most generally accepted explanation is that given by Professor Verrill, who says that the phosphorescence protects its possessors. Most cœlenterates, he says, are possessed of nematocysts or nettling cells, and the phosphorescence may serve to give notice to predaceous fishes that feed largely on hydroids, etc., that these nettling cells are present, and thus induce them to seek other provender. It is somewhat unfortunate for this argument that few if any of the cœlenterates that are remarkable for their phosphorescence possess nettling cells that are likely to be regarded by a hungry fish as at all formidable.

Another explanation is, however, possible. The food of the cœlenterates consists mainly of either crustacea of the smaller sorts, their embryos, protozoans, or unicellular plants. Now most of the crustacea have functional eyes, and it has been repeatedly demonstrated that they are attracted by light, both artifical and natural. Crustacean embryos usually have eyes that are proportionally very large. In many cases these too are attracted by light, and it is reasonable to suppose that they are attracted by phosphorescent light. If this is true, the light emitted by the fixed cœlenterates would cause the small crustaceans, and more surely their embryos, to congregrate near the illuminated areas and thus be captured. The process would be analogous, perhaps, to what is known as the effect of alluring coloration among insects and birds. The phosphorescence would thus be of direct utility to the fixed cœlenterates in securing food.

The application of this idea may be still further extended to include the attraction of Protozoa and even diatoms, both of which groups contain many species that are strongly attracted by light, which appears to act as a direct stimulus to both unicellular animals and plants by virtue of its well-known effect upon protoplasm itself.

One other fact, bearing directly on our discussion, that impresses itself strongly upon every one who has had actual experience in deep-water dredging, is the very uneven distribution of life over the sea bottom. In other words, the distribution is 'spotted.' A haul over certain areas will result in a dredge full of a profusion of animal forms, while the immediately adjacent bottom, although of apparently identical nature, will yield practically nothing. Our party repeatedly observed this while dredging on the Pourtales Plateau. It seemed as if species were distributed in densely crowded colonies of very limited areas. Sometimes one particular species seems to have fairly carpeted the bottom, and in other localities a great assemblage of species would be secured at a single haul, showing a profusion of life, perhaps greater than can be found on a similar area either in shallow water or on land. Again the tangles would come up with nothing but sand and bottom débris.

It seems, then, that we are justified in

concluding that the sea bottom is, for the most part, utterly dark, but that there are scattered areas, often of considerable, extent where animal life is aggregated in masses, and where the phosphorescent light is of sufficient quantity to render the colors, laid on as we have seen in broad patterns, visible to animals with functional eyes. These colors would then be of the same utility to their possessors as in the upper world, and act as protective, aggressive, directive, attractive and alluring agencies. We are further justified in maintaining that phosphorescence is in all cases of direct utility to its possessors, and that in the fixed eyeless forms it serves to attract food, and perhaps in some cases to warn enemies of the presence of the irritating nettling cells.

As a sort of compensation for the feebleness of the phosphorescent light, and for its absence over vast areas, many animals, especially fishes and crustaceans, are furnished with very large eyes, or with organs which serve as lanterns, or with enormous mouths and stomachs to make the most of a very occasional square meal, or with greatly elongated feelers or tactile organs. Others still are provided with a luminous bait to attract the prey.

The main thing that I would impress upon you this evening is the fact that we have a right to expect to find utility for every character, not rudimentary, possessed by animals, a utility not necessarily to the individual, but certainly to the species. And I would protest most vigorously against the vain and impotent conclusion that anything is useless simply because we have been too ignorant or too indolent to find its function. I have small patience with a statement such as the following taken from a recent writer on animal coloration: "The inevitable conclusion, therefore, from these facts appears to be that the brilliant and varied colorations of deep-sea animals are totally devoid of meaning; they can not be of advantage for protective purposes or as warning colors, for the simple and sufficient reason that they are invisible."

This sort of thing is deeply injurious to science, because it is a helpless surrender of one of the most powerful of all incentives to research. If we can loll back in our easy chairs and declare that natural phenomena of widespread occurrence are meaningless, or, what amounts to the same thing, that Nature is guilty of a lot of vapid nonsense, we have indeed sold our scientific birthright for a mess of exceedingly thin pottage, and have stultified ourselves in the eyes of the thinking world.*

REMINISCENT REMARKS ON THE TOP.

SOME time ago, I wrote a short article in this journal,† in which among other things I endeavored to give an intelligible explanation of all that, from an elementary point of view, is interesting in the dynamics of the top. The treatment of this famous and ubiquitous apparatus in all text-books known to me is too sketchy and, didactically considered, useless. In my judgment this is a real gap and well worth filling. But my friends have so frequently and even quite recently taken me to task for my explanation, that I feel bound to reassert its correctness here.

Everybody will agree that up to the second order of approximation, and a vigorously spinning top or gyroscope, in which $\dot{\theta}$ is the polar velocity and φ and ψ the parameters of azimuth and altitude,

* Most of the facts and sometimes whole paragraphs concerning the coloration of deep-sea animals and phosphorescence, have been taken from the following papers by the author: 'The Color of Deep Sea Animals,' *Proc. Iowa Acad. of Sci.*, Vol. VI.; 'The Utility of Phosphorescence in Deep Sea Animals,' *Am. Nat.*, Oct., 1899.

† SCIENCE, V., pp. 171–5.

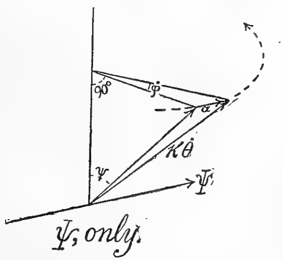
$$\Psi = K\dot{\theta} \sin \psi \cdot \dot{\varphi}, \qquad (1)$$

$$\Phi = - K\dot{\theta} \sin \psi \cdot \dot{\psi}, \qquad (2)$$

will express the motion. Here Ψ and Φ are the torques around the horizontal and vertical axes, respectively, and K the polar moment of inertia; friction is disregarded.* Hence $\dot{\theta}$, $\dot{\varphi}$, $\dot{\psi}$, are of the first order of small quantities, $\ddot{\varphi}$ and $\ddot{\psi}$ of the second order.

The point is now to show that these equations are reproduced in my geometrical constructions relative to the common theorem of the equivalence of torque, and the change of angular momentum per second around any particular direction.

I. *Torque* (Ψ) *around the horizontal axis only. Precession.*—Take any two positions of the top axis, a second of time in position apart. Lay off the angular momenta $K\dot{\theta}$,



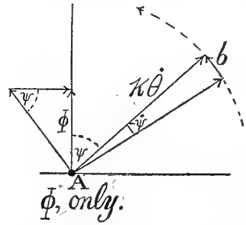
along these axes. They are equal by the premises. Hence the horizontal arc, a, is the rate of change of angular momentum due to the torque Ψ around the parallel axis shown. In the second of time stated, the angle of azimuth has changed by $\dot{\varphi}$, as shown in the figure. Therefore, the arc

$$a = K\dot{\theta} \sin \psi \cdot \dot{\varphi},$$

and hence

$$\Psi = K\dot{\theta} \sin \psi \cdot \dot{\varphi},$$

II. *Torque* Φ *around the vertical axis only.*—This requires gyroscopic mounting. Let the horizontal axis be seen end on at A. Take two positions of the top axis, a second of time in position apart. Lay off the (equal) angular momenta, $K\dot{\theta}$, along these



axes. Then the arc b is the rate of change of angular momentum, and the angle, $-\dot{\psi}$, subtended, the speed in altitude. Hence

$$b = -K\dot{\theta} \cdot \dot{\psi}.$$

The arc, b, cannot be resolved with advantage, for there is no way of accounting for both components. Φ, however, may be resolved; for if one component is made parallel to b, this is the equivalent of b; whereas if the other component tends to twist across A (in a plane at right angles to 'around A'), *i. e.*, in the plane of this axis, it can produce stress only, but no motion. Hence, as seen in the figure, the effective *component* is $\Phi / \sin \psi$, a result a little subtle, I grant, but none the less logically straightforward. Therefore

$$\Phi / \sin \Phi = b,$$

whence

$$\Phi = -K\dot{\theta} \sin \psi \cdot \dot{\psi}.$$

Of course my explanation was intended for the man interested in *spinning* tops. The other man, who prefers the top toppling through all stages of inebriety, may take such solace as comes from products of parameter speeds and accelerations. But for him I have no message other than my blessing.

CARL BARUS.
BROWN UNIVERSITY, PROVIDENCE, R. I.

* Otherwise, if there is polar acceleration, $\Phi = - K (\dot{\theta}\dot{\psi} \sin \psi - \cos \psi \cdot \ddot{\theta})$ may be deduced without difficulty by the method of § II.

THE SOLAR ECLIPSE.

In view of the fact that some time must elapse before it is possible to publish a complete account of the results of observations on the solar eclipse of May 17th–18th, the following letter, written from Padang by a correspondent of the London *Times*, describing the preliminary arrangements, is of interest:

The last few days of our very prosperous voyage across the Indian Ocean in the Dutch mail boat *Koningin Regentes* have brought with them the sense that we are coming to a land where it is 'always afternoon.' But our days of eating lotus were nearly over just as we reached this beautiful land. The lighthouse close to Siberut, rising high above the palms, warned us that Padang was not more than ten hours away. The sight of this light produces the same thrill that seizes one when, after crossing the Atlantic, the Fastnet comes into view and tells that the voyage is safely accomplished. It is the first land that we sighted since we passed the splendid headland of Somaliland, Cape Guardafui, on March 27th; our course took us through the Maldives at night; and, though we passed through the '8° Canal,' Minicoy was left so far to the north that we got no glimpse of the light. All the members of the expedition who have traveled out by this direct route to make observations during the total eclipse of the sun visible in Sumatra disembarked at Padang.

Three parties of observers have traveled out on the *Koningin Regentes*—(1) the English expedition, consisting of Mr. H. F. Newall, of Cambridge, Mr. F. W. Dyson, of the Royal Observatory, Greenwich, accompanied by Mrs. Newall and by Mr. J. J. Atkinson, who has volunteered assistance to the party in this distant land, just as he did to the Astronomer Royal's party last year in Portugal; (2) the Dutch expedition, consisting of Dr. A. A. Nijland, of Utrecht, Dr. W. H. Julius, professor of experimental physics at Utrecht, and Mr. J. H. Wilterdinck, of the Leiden Observatory, accompanied by Mr. J. H. Hubrecht, a son of Professor Hubrecht, the eminent embryologist, who lately received the honorary degree of Sc.D. at Cambridge University; (3) a party from the Massachusetts Institute of Technology, consisting of Professor Burton, Mr. H. W. Smith, Mr. G. Hosmer, and Mr. G. H. Matthes. The instruments of all these parties were also carried by the same mail boat, which starts from Amsterdam and calls at Southampton and Genoa.

The eclipse of the sun which will occur on the 17th–18th of May is of special interest on account of the long duration of the total phase. The shadow of the moon will first touch the earth at sunrise near Madagascar, and in the course of the next five hours it will traverse a long path on the earth's surface. Passing at first in a northeasterly direction over Mauritius, it speeds across the Indian Ocean and traverses Sumatra and Borneo. It grazes the equator, but only a small part of the shadow touches the northern hemisphere. Then its course bends southeastwards and passes over the Malay Archipelago, Celebes, Seram, and thence over New Guinea. At sunset in the Coral Sea, between Melanesia and Australia, the shadow leaves the earth.

The partial phase of the eclipse will be visible over a vastly greater region of the earth's surface, as far north as Somaliland, India, Siam, and China, and also over the whole of Australia; but the real interest of the eclipse lies in the total phase, which can only be observed at stations lying on the line indicated. The shadow of the moon will be about 140 miles across as it passes over Sumatra, and it will travel with a speed of about 1,500 miles an hour. Hence any observer stationed near the path of the center of the circular shadow will be in the shadow for about a tenth of an

hour, or, if more exact calculations are used, for 6 min. 29 sec.

In recent eclipses the duration of totality has been much shorter; thus in America, Spain, and Algiers, in May, 1900, the total phase lasted not much more than one minute; whilst in India, in January, 1898, the duration was only a little more than two minutes in the most favorable stations.

Hence the coming eclipse is welcomed as an unusual opportunity for collecting observations by the photographic methods which play so important a part in modern investigations. Especially in spectroscopic researches is the photographic method serviceable; for by the nature of this kind of research the light gathered by the instruments is spread out over a much greater extent of the photographic plate. Accordingly to collect information about the spectrum of the faint light of the corona long exposures of the photographic plate are necessary.

The valuable information published by the *Koninklijke Natuurkundige Vereeniging* in Batavia over the signatures of Major Muller, the chief of the Trigonometrical Survey, and Dr. Figee, the director of the Meteorological Observatory, Batavia, showed that the weather conditions were probably most favorable, or, shall we say, least unfavorable, in Sumatra, especially near the west coast. It is therefore not surprising that most of the observing parties converge on Padang, the port that gives access to the province of the West Coast, and lies actually on the course of the moon's shadow.

The joint permanent eclipse committee of the Royal Society and the Royal Astronomical Society favored the sending of an expedition to Mauritius, and we understood on leaving England that Mr. E. W. Maunder, of the Royal Observatory, Greenwich, was to go thither to make observations in conjunction with Mr. Claxton, the director of the Royal Alfred Observatory, Mauritius. We also learn that Mr. D. P. Todd, of Amherst, U. S. A., is to be stationed at Singkep, an island noted for its tin mines, lying on the east coast of Sumatra, due south of Singapore. Otherwise all the observers have come to Padang and are receiving the most courteous and helpful reception by the Dutch authorities. Probably most of the parties have similar obligations to acknowledge. The English expedition received every assistance from Mr. Joekes, the Governor of Sumatra's west coast. Thus Mr. Dyson was at once made welcome to use the Government launch to make preliminary inspection of Trusan Bay and of the island Aoer Gedang, about six miles to the west of Painau and 30 miles to the south of Padang; whilst Mr. Newall received every assistance from Mr. Delpeat, the chief of the railways, to go inland and search for a suitable site on the east side of the Barisan Mountains. And so within four days of landing at Padang the sites for observing stations of the English expedition were chosen.

In order to increase the chances of securing observations of the eclipse, the parties distribute themselves as far apart as possible. The extreme stations in Sumatra are occupied by English parties. Mr. Dyson and Mr. Atkinson, assisted by his Majesty's ship *Pigmy*, a gunboat commanded by Lieutenant Oldham, R.N., and sent from the China Station to assist the observers, have established their camp on the island Aoer Gedang, and will be the first to catch the eclipse. Here the program of observations will be to secure (1) photographs of the corona on a large scale to show details of the structure; (2) photographs on a small scale to get the greatest possible extensions of the coronal streamers; (3) photographs of the ultra-violet spectrum of corona and chromosphere and also of the green and yellow spectrum, with slit spec-

troscopes in both cases. At the eastern extremity of the Sumatra stations Mr. Newall will be established at Doerian, above the Oembilien Coal Mines, near Sawah Loento, at the extreme end of the railway. The engineer of the mines, Mr. van Lessen, has put a house at the disposal of this party, and a very good site has been found close at hand for the setting up of the instruments, which consist of (1) a powerful flint spectroscope, to be used in an attempt to determine whether the corona rotates ; (2) a quartz spectroscope, to be used for photographing the extreme ultra-violet spectrum and for a special search for Fraunhofer lines such as might be attributed to sunlight reflected by dust in the corona ; (3) a cœlostat, to be used in connection (*a*) with polariscopic cameras in investigating the polarization of the light of the corona, (*b*) with a telephoto camera in photographing the corona, (*c*) with a powerful grating spectroscope in getting monochromatic images of the corona. This station is 1,200 ft. above sea level and it is at a considerable distance to the east of the main range of the Barisan Mountains. It is to be hoped that, with the considerable uncertainty that exists in the weather and wind conditions, one at least of these extreme stations may be favored with a good view of the eclipse. At various points between these extreme stations many other parties are established. The Dutch party have a large camp at Karang Sago, close to Painau, on the coast, and have an extensive programme, including (*a*) photographs of the corona with cameras of very varied dimensions ranging from a 40-ft. telescope with aperture f191 to a short camera with aperture f13.5 ; (*b*) spectroscopic observations of the corona and chromosphere ; (*c*) polariscopic observations to be carried out visually ; (*d*) measurements of the heat-radiation of the corona. (Professor Julius has constructed a specially delicate thermopile with a view of getting absolute measures of the total radiation of the whole corona and comparing it with that of the uneclipsed sun.) A party will probably also be sent with a prismatic camera to Fort de Kock, near the northern limit of the shadow.

The observers from the United States Naval Observatory, together with affiliated parties from the Yerkes Observatory and the Smithsonian Institution, are established in an excellent site, the old fort at Solok. Here Professor Barnard is setting up his cœlostat and 61-ft. telescope with which he is going to photograph the corona, exposing plates 40 in. square for $2\frac{1}{2}$ minutes, being led to expect detail right up to the edge of these plates. For the shorter exposures he will be content to use smaller plates 30 in. square and 17 in. square. Professor Abbot and Mr. Draper, from the Smithsonian Institution, come with this party and find a room in the fort that will serve admirably for their bolometric apparatus. Dr. Humphrys will probably take spectrographic apparatus to Fort de Kock not far from the northern edge of the moon's shadow. Mr. Jewell brings out a battery of gratings of unusual size, both plane and concave, and will use films 36 in. long and $2\frac{1}{2}$ in. wide in getting extended spectra of the chromosphere and corona, special attention being given to the ultra-violet region of the spectrum. Professor Skinner, who is in charge of the whole party, has also brought large cameras, which will be used in a search for an intra-mercurial planet.

Mr. Perrine, from the Lick Observatory, has established his camp on the race-course at Padang, and is setting up a 40-ft. telescope to point direct at the sun. He also has four 12-ft. cameras to be mounted on one axis and used in a search for Vulcan ; in this research 12 plates, 17 in. by 14 in., will be exposed, covering a wide range on either

side of the sun, duplicate plates of each region being taken. He has also two spectroscopes, each with a single prism and with polarizing apparatus, for special study of the coronal light.

Members of the party from the Massachusetts Institute of Technology have found a good site near Sawah Loento, and are setting up in addition to their eclipse intruments, a number of geodetic instruments, among others a short-period pendulum. They also have a program of observations with magnetometers in continuation of their work in last year's eclipse, in which definite movements were detected in the magnets at the moment of totality.

The Japanese party, including Professors Shin Hiroyama and Seiji Hirayama, of Tokio, and five Japanese assistants, will probably find a station at Padang, as also will the parties from the Jesuit Colleges at Calcutta and Manila. We learn that a German expedition is to arrive on April 28th, and that Count de la Baume Pluvinel will arrive on the same date and proceed to Solok.

It is too early to speak of the chances of clear skies for the various parties, and at present it would seem that success is very precarious. It is fortunate that totality occurs at midday; the sky is frequently clear then, though many fleeting clouds pass over the sun. Meanwhile, the preparations are being pressed forward with a good will by observers and resident authorities alike.

SILAS W. HOLMAN.

Silas Whitcomb Holman was born at Harvard, Massachusetts, Jan. 20, 1856, and graduated from the Massachusetts Institute of Technology in 1876, having made a specialty of the study of physics throughout his course. He was thereupon appointed to a position as assistant in the physical laboratory of that institution, but on account of illness did not enter upon his duties until a year later. Continuing in the service of the Institute, he was promoted to more advanced positions and was made professor of physics in 1893. Even at this date his health, never firm, had become much impaired, and a few years later it became necessary for him to relinquish active work. In 1897 he was made emeritus professor of physics. He died April 1, 1900.

Professor Holman's original contributions to science are of high merit and give evidence both of great skill in manipulation and of remarkably clear insight into the choice of methods for conducting a difficult investigation.

The most important of his researches are those upon the viscosity of air and carbonic acid as affected by temperature, which were published in the *Proceedings* of the American Academy of Arts and Sciences in 1876 and 1885, the first of which was based upon his graduating thesis at the Institute of Technology. These contain by far the most complete study of this difficult subject which had been made up to their date, and the results are still of standard value. Indeed, within the past few years, they have played an important part in the advancement of the kinetic theory of gases.

In the same *Proceedings* for 1886 is found a further noteworthy paper, written in conjunction with one of his pupils, upon the determination of fixed reference points for thermometric measurements at high temperatures in which several such points are established.

A number of years later, in 1895, appeared another group of papers, the last published by him, relating to the thermo-electric measurement of high temperatures, and a single paper upon calorimetry, which subjects had occupied much of his attention for some time previous. Of these, the one entitled

'Thermo-electric Interpolation Formulæ' is particularly valuable for its critique of the various methods of interpolation which have been employed in dealing with the results of high temperature observations, and that upon the 'Melting Points of Aluminium, Silver, Gold, Copper and Platinum,' published in collaboration with his pupils, Messrs. Lawrence and Barr, contains what are undoubtedly the best measurements of the points of fusion of these metals that had been obtained at the time of their publication. A third paper contains a description of a novel method of calibrating the LeChatelier thermo-electric pyrometer, and the fourth a new method of applying the cooling correction in measurements of the heat of combustion.

The papers of Professor Holman, thus far referred to, have all been published in the *Proceedings* of the American Academy. Several others of minor importance have appeared in different scientific journals. An extended critique upon thermometry of precision, presented at the Boston meeting of the American Association for the Advancement of Science in 1880 unfortunately was never printed.

Besides his published researches, Professor Holman was the author of several valuable scientific works. The two volumes of 'Physical Laboratory Notes,' prepared for the use of his pupils in the Massachusetts Institute of Technology, embody the results of many years of successful experience in teaching and form an important contribution to the literature of the subject. They contain much original matter and exhibit a rare discrimination in the selection and comparison of the methods of measurement which are discussed. This is particularly the case with the volume relating to electrical measurement and testing.

In 1892 he published a treatise upon 'The Discussion of the Precision of Measurements,' the basis of which consisted of the notes of lectures given to his classes. This volume, which is quite unique in its contents, contains in convenient form a very compendious and lucid consideration of the application of the principles of least squares to the theory of observations, the calculation of their precision and the choice of proportions in designing physical apparatus to be used for measurement. Its value as a text-book has been very great.

The collection of four- and five-place logarithmetic tables, prepared in 1896, embodies several features of marked originality, and is prefaced by a brief but exceedingly useful discussion of the fundamental principles of computation which contains many useful suggestions for the economizing of labor.

The last work written by Professor Holman, entitled, 'Matter, Energy, Force and Work,' appeared in 1898 and is of a character widely different from any of those which preceded it. It is a philosophical study of the fundamental concepts of modern physics, in which the subject is approached from the point of view that matter and energy, rather than matter and force, are the primary entities with which physics, has to deal, and that matter itself may be dependent upon energy for its own existence. While not technical in its character, and intended especially for the help of teachers not wholly familiar with modern views, it is distinguished throughout by great clearness and is a remarkable presentation of the newer modes of viewing the subjects which it considers.

Valuable as are his scientific publications, however, Professor Holman's great work was that of a teacher of young men in the laboratory. From the beginning of his service as an assistant in the Rogers Laboratory of Physics his influence was marked, and by his patient labors extending through many years, he brought the work which was under his charge to a high state of develop-

ment. He possessed great skill in the planning of apparatus and methods and remarkable judgment as to the processes best suited either for purposes of instruction or for the securing of accurate scientific results. To the development of the Laboratory of Electrical Measurements in the Massachusetts Institute of Technology he gave for years his best endeavors, and to him is due the success of its work. He was also placed in charge of the newly instituted Laboratory of Heat Measurements, and though prevented by failing health from developing this as he would have chosen, he laid a solid foundation for those coming after him.

Professor Holman was born a teacher, and never grew weary in his profession. His personal relations with his pupils were very intimate. By that example which is better than the wisest precept, he impressed upon them the preeminent necessity of thoroughness, accuracy and honesty in all the work which they might be called upon to perform, either as students or in professional life. He is remembered by them with the most affectionate regard.

Reference has already been made to the interference of ill-health with the prosecution of the labors of Professor Holman. In fact, after reaching manhood he was never in good health, and during almost the whole of his active life as a teacher he struggled with a painful chronic disease, which gradually, though with some intermissions, sapped his strength. His cheerful disposition and persistence in carrying on his work were such that none but those who knew him well were aware of the fact that it was only his indomitable courage which prevented him from yielding to his malady for some years before it finally overcame him. In the spring of 1890 he was obliged to discontinue work for a time. He spent the following year abroad and came home much improved in health; but the relief was only temporary. In 1895 he finally gave up his work of instruction. For some years after this, however, though confined to his chair and at last even deprived of his sight, he continued to labor diligently and published the tables of logarithms and the work on matter and energy mentioned above. His latest years were his best ones, and his whole life was a fine illustration of the manner in which a noble spirit may rise superior to circumstances and produce the best results under conditions to which an ordinary mind would utterly succumb.

CHAS. R. CROSS.

SCIENTIFIC BOOKS.

Botany—An Elementary Text for Schools. By L. H. BAILEY. New York, The Macmillan Company. 1901. 8vo. Pp. xvi + 356. Price, $1.10.

Foundations of Botany. By JOSEPH Y. BERGEN, A.M. Instructor in Biology, English High School, Boston. Boston, U. S. A., Ginn & Company. 1901. 8vo. Pp. xii + 412 + 258. Price, $1.50.

Within the past three or four months two notable text-books on high-school botany have appeared, the one from the ready pen of Professor Bailey, of Cornell University, to whom we are already indebted for so many helpful and suggestive books on various phases of plant life, the other from Instructor Bergen, of one of the Boston High Schools, who also has the distinction of having written acceptably in the preparation of an earlier, very useful, although much simpler, text-book for high-school students.

The two books are quite different in both content and mode of treatment. Professor Bailey takes the quite extreme position that 'the schools and teachers are not ready for the text-book which presents the subject from the viewpoint of botanical science,' and is particularly opposed to the use of the compound microscope in high schools, as when he says: "The pupil should come to the study of plants and animals with little more than his natural

and native powers. Study with the compound microscope is a specialization to be made when the pupil has had experience, and when his judgment and sense of relationship are trained." A little later he says: "It is often said that the high-school pupil should begin the study of botany with the lowest and simplest forms of life. This is wrong. The microscope is not an introduction to nature." We do not quite like the tone of non-approval in regard to science and specialists which is heard now and then in the author's preface, as in the first sentence quoted, where botanical science is referred to, and in this, "A book may be ideal from the specialist's point of view, and yet be of little use to the pupil and the school," and, "Every statement in an elementary text-book has two values—the teaching value and the scientific value," and, again, "Education should train persons to live, rather than to be scientists," and still, again, "Expert specialists are so likely to go into mere details and to pursue particular subjects so far, when teaching beginners, as to miss the leading and emphatic points." There is already too much of this feeling abroad in the land, as witness the recent discussions in Congress on matters of scientific importance, and there is no call for any one to increase it by discrediting any department of science or those who have devoted their lives to scientific work. Of course, we know that the author does not wish to be understood in this way, but his wording is unfortunate and will certainly be so understood by many people.

It would be unfair to quote the foregoing sentences, with the wording of which at least we most emphatically do not agree, and refrain from some quotation of those in regard to which there will be no question, as for example, "In the secondary schools botany should be taught for the purpose of bringing the pupil closer to the things with which he lives, of widening his horizon, of intensifying his hold on life," and, "Botany always should be taught by the 'laboratory method': that is, the pupil should work out the subjects directly from the specimens themselves."

The book is divided into four parts under the titles of 'The Plant Itself,' of 195 pages; 'The Plant in its Environment,' of 37 pages; 'Histology, or the Minute Structure of Plants,' of 42 pages, and 'The Kinds of Plants,' of 66 pages. The first is almost entirely devoted to the gross anatomy and elementary physiology of seed plants, but 24 pages being given to the structure of algæ, fungi, lichens, liverworts, mosses, ferns, horsetails and quillworts. The second part is ecological in a very elementary way, the treatment being well adapted to the needs of the pupils for which the book is designed. The third part, on the contrary, is quite severely technical, in spite of the author's prefatory remarks about the compound microscope, including such technical matters as fixing, imbedding, sectioning with the microtome, staining and mounting, and even not excluding karyokinesis! Part IV. consists of a handy little manual about 300 selected species of ferns and seed plants. Throughout the book the illustrations, of which there are 500, are very pretty, many of them being 'half-tone' reproductions of photographs.

We distinctly do not like the lists of questions at the close of the chapters, each question matching an italic or heavy-type sentence in the text. These will certainly lead to grave abuses. On the other hand, there is much to commend in the book. It is charmingly written by one who knows a great deal about plants, and who is desirous of having the young people know plants as he knows them. His enthusiasm will inspire many a pupil to take up the serious study of plants who otherwise might have passed them by had the subject been presented in a different way, especially where the teacher has little knowledge of botany.

In Instructor Bergen's book we have less divergence from the generally accepted principles in secondary botanical teaching. The author 'has attempted to steer a middle course between the advocates of the out-of-door school and of the histological school of botany-teaching.' That he is not afraid of the scientific or technical aspects of botany is shown by the following quotations:—"The latest authorities in the various departments of botany have been consulted on all doubtful points, and the attempt has been to make the book scientifically accurate throughout, yet not unduly difficult."

* * * "The author has no sympathy with those who decry the use of apparatus in botany teaching in secondary schools and who would confine the work of their pupils mainly within the limits of what can be seen with the unaided eye. If the compound microscope plainly reveals things shown only imperfectly by a magnifier and not at all with the naked eye, use the microscope. If iodine solution or other easily prepared reagents make evident the existence of structures or substances not to be detected without them, then use the reagents." * * * "When the university professor tells the teacher that he ought not to employ the ordinary appliances of elementary biological investigation in the school laboratory because the pupils cannot intelligently use them, the teacher is forced to reply that the professor himself cannot intelligently discuss a subject of which he has no personal knowledge." It is evident from the foregoing that the two authors approach the task of outlining the work for the pupil in the secondary schools with very different ideas as to what may be and should be done.

The book contains three parts, viz., 'Structure, Function and Classification of Plants,' 'Ecology, or Relations of Plants to the World about Them,' 'Key and Flora.' The first part begins with the seed and its germination, followed by chapters on the movements, development and morphology of the seedling, roots, stems, buds, leaves, flowers and fruits. In all this there are many physiological experiments, as well as much work with the compound microscope, one short chapter on protoplasm and its properties being interpolated. We have illustrated here, also, the usual exaggerated emphasis too commonly given to the flowering plants, which have 235 pages given to them as against but 63 pages for the slime moulds, bacteria, fresh-water and marine algæ, fungi, lichens, bryophytes, ferns and their allies. The second part is ecological, and follows the usual German treatment of this subject. It contains much interesting information, and pretty and suggestive pictures, but we do not look for much scientific training from the pupil's study of these chapters. At best the pupil will obtain but a very general and vague notion of the many things referred to here. Some serious errors mar this portion of the book, as in the treatment of 'plant formations' and 'prairies' on page 310.

The 'Flora' is much like most other manuals for beginners, which are made easy by the device of omitting certain families, which among teachers are reputed to be quite too difficult for the young student. It includes seed plants only.

CHARLES E. BESSEY.

THE UNIVERSITY OF NEBRASKA.

Text-Book of the Embryology of Invertebrates. By DR. E. KORSCHELT and DR. K. HEIDER. Translated from the German by MATILDA BERNARD. Revised and edited with additional notes by MARTIN F. WOODWARD. Vol. IV., Amphineura Lamellibranchia, Solenoconcha, Gastropoda Cephalopoda, Tunicata, Cephalochorda. London, Swan, Sonnenschein & Co., Ltd.; New York, The Macmillan Co. 1900. 18s.

This is the concluding volume of the somewhat tardy translation of Korschelt and Heider's standard 'Lehrbuch der vergleichenden Entwicklungsgeschichte der wirbellosen Thiere' 1893. As the editor notes in the preface, invertebrate embryology has made immense advances during the last eight years; thus a mere translation of the thorough and scholarly German work would fail to give an adequate account of the present state of knowledge. The translation itself by Matilda Bernard is a very faithful rendering into good English of the original. But the separation of the offices of translator and editor has necessarily limited the revision largely to numerous footnotes and some interpolations. This has the decided defect of preserving conspicuously all that later researches have shown to be errors in the original German edition, and of relegating the corrections to subordinate paragraphs or footnotes in small type easily overlooked by the average student. Thus, to take but a single example, the account of the cleavage of the lamellibranch ovum in the original has been shown to be incorrect, and it is illustrated by diagrams that faithfully and forcibly confirm the error. Yet both are given literally in the translation, and it would re-

quire one already versed in the literature to extract the truth from the footnote revision. Even, however, if the student succeeds in this, he will soon be confused by the plain unrevised statement on p. 106 that the course of cleavage is different in lamellibranchs and gastropods, whereas the recent work has demonstrated a fundamental similarity. It is also to be regretted that the editor should, apparently, have felt unable to replace some of the older figures with more accurate recent ones; not a single figure from the newer works is introduced.

A feature of the revision that will be heartily welcomed is the appendices to the lists of literature, in which the works published since 1893 are included. An important omission from the usually full and accurate lists is that of Heath's valuable paper on Ischnochiton, the more noticeable from the scantiness of the literature of the embryology of the Amphineura.

Misprints are not common, but it is rather a serious one that credits Hatschek's figures of the cleavage of *Amphioxus* given on p. 537, to Salensky. The present writer finds his initials once F. K. and again F. H., which arouses the suspicion that others also may have ground for complaint.

Take it all in all, the book is a good translation of the standard work on the subject, and the revision will at least suffice to guide the serious student to the more recent literature.

F. R. L.

The Play of Man. By KARL GROOS. Translated by ELIZABETH L. BALDWIN, with a preface by J. MARK BALDWIN. New York, Appleton & Co. 1901. Pp. 412. Price, $1.50.

This is not a drama, as the ambiguous title might signify, but a scientific treatise on sport and pastime, the performance of life's activities not for serious purposes, but for the solitary or cooperative pleasure in them. The author includes in his term the playful activity of the sensory apparatus in feeling, temperature, taste, smell, hearing and sight; the playful use of the motor apparatus, and the playful use of the higher mental powers. His second order of play is socionomic, that is, it takes two or more to fight, play chess, torment, haze, court, cooperate in diversion. The facts and results of over play and diseased play are not neglected.

Part III. is devoted to theoretical explanation of sport, the author finding its groundwork in the following:

1. The discharge of superabundant vigor—the physiological cause.

2. Activities of ancestors wrought in their children in the form of hereditary predispositions—the biological cause.

3. Pleasurableness and freedom from purpose—the psychological cause.

4. The enjoyment of imitating what produces agreeable or intense feelings—the esthetic cause.

5. The strengthening of the social tie—the sociological cause.

The closing pages are devoted to the relation of play to pedagogics. We have only space to quote one sentence, "At school one should learn to work, and he who does everything playfully will always remain a child." The reader will find throughout the work a becoming modesty in view of a new science, and a goodly portion of playfulness to relieve the monotony of dull classification.

O. T. M.

Text-book of Inorganic Chemistry. By VICTOR VON RICHTER. Edited by PROFESSOR H. KLINGER, University of Königsberg. Authorized translation by EDGAR F. SMITH, Professor of Chemistry in the University of Pennsylvania, assisted by WALTER T. TAGGART, Instructor in Chemistry. Fifth American from the tenth German edition. Carefully revised and corrected. With sixty-eight engravings on wood and colored lithographic plate of spectra. Philadelphia, P. Blakiston's Sons & Co. 1900. Pp. 430. $1.75.

The continued popularity of this book is shown by the frequent editions; in this edition, notices on liquid air, the new gases in the atmosphere, and ten pages of physical chemistry introduced into the chapter on metals, indicate careful revision, and a desire to bring the book up to date, without changing its general character. The characteristic of von Richter's book is the great amount of condensed

information which it contains compared with other books of its size; indeed, it might be criticized as giving too much for a text-book for beginners, too little for advanced students; yet as this has always been the characteristic of the book through the different editions, the popularity of the work may be held to answer such criticism.

SCIENTIFIC JOURNALS AND ARTICLES.

The Journal of Comparative Neurology for April opens with two articles from the Neurological Laboratory of the University of Chicago, by Shinkishi Hatai. The first on 'The Finer Structure of the Spinal Ganglion Cells in the White Rat,' describes and figures two varieties of spinal ganglion cells and considers the smaller variety, the chromophilic cells of Nissl, to be an immature stage in the development of the larger variety. In the second paper, 'On the Presence of the Centrosome in Certain Nerve Cells of the White Rat,' the centrosome is described in nerve cells of new-born rats from the following localities: great pyramids of the cerebral cortex, Purkinje's cells, nucleus dentatus, ventral horn of spinal cord and spinal ganglion cells. The centrosomes were less easily demonstrated in the adult and were not found at all in some of these localities. Earl E. Ramsey, of Indiana University, describes 'The Optic Lobes and Optic Tracts of *Amblyopsis spelæus* DeKay,' a blind fish from the limestone caves of the Ohio Valley in which the eye and optic nerve are almost wholly degenerate. The optic lobes of the brain are greatly shrunken, the optic tracts and all parts of the optic tectum directly related to them are entirely wanting and the remaining layers are generally reduced in thickness. G. E. Coghill, of Brown University, discusses 'The Rami of the Fifth Nerve in Amphibia.' In the course of an examination of the nerve components of *Amblystoma*, he clears up the morphology and homologies of the maxillary and ophthalmic branches of this *Urodele* and of the frog. Dr. Strong (Columbia University) presents a 'Preliminary Report upon a Case of Unilateral Atrophy of the Cerebellum,' in which the left hemisphere of the cerebellum was almost completely wanting. Finally, 'A Bibliography of the Literature on the Organ and Sense of Smell' is given by Dr. H. Heath Bawden, of the University of Iowa. This list contains 885 titles, including anatomical, physiological and psychological subjects.

The Popular Science Monthly for May begins with an account of 'The Carnegie Museum,' by W. J. Holland. Frederick A. Cook describes 'The Aurora Australis,' as observed from the *Belgica*, with illustrations showing some of the many forms assumed by this interesting phenomenon, and we have the first instalment of a paper on the 'Progress and Tendency of Mechanical Engineering during the Nineteenth Century,' by Robert H. Thurston. An article on 'Primitive Color Vision,' by W. H. R. Rivers, gives a very good résumé of the evidence on which is based the deduction that color vision has been a comparatively recent acquirement of the human race, and the fifth portion of 'A Study of British Genius,' by Havelock Ellis, is devoted to childhood and youth. Under the title 'The Frog as Parent,' E. A. Andrews gives an interesting account of some of the curious breeding habits to be found among the frogs. In 'Recent Physiology,' G. N. Stewart tells of some of the lines of modern investigation and their results. The final paper, by David Starr Jordan, on 'The Blood of the Nation,' is a study of the decay of race through the survival of the unfit.

The Plant World for April contains the following articles: 'Hints on Herborizine,' by A. H. Curtise; 'Notes on the Flora about Nome City,' by J. B. Flett; 'The Native Oak Groves of Iowa,' by T. J. and M. F. L. Fitzpatrick, be-

sides brief articles, including a note on a fossil flower related to Hydrangea. The supplement, devoted to 'The Families of Flowering Plants,' by Charles Louis Pollard, treats of the Sarraceniales and Rosales.

An editorial article in the *Observatory* accuses the *Astrophysical Journal* of reprinting without credit an article on the 'Siderostat' by M. Cornu. As the *Bulletin astronomique*, in which the French copy of the article appeared, was published in February, 1901, and the number of the *Astrophysical Journal* in March, 1901, the editor of the *Observatory* must appreciate the promptness of American methods. As a matter of fact important European articles on astrophysics are published by the authors simultaneously in the *Astrophysical Journal.* This makes the concluding sentence in the editorial in the *Observatory* interesting: "they print the same paper in several journals, so that it may be widely read, whereas in Europe we have made it a point *not* to reprint."

SOCIETIES AND ACADEMIES.

SECTION OF ANTHROPOLOGY AND PSYCHOLOGY OF THE NEW YORK ACADEMY OF SCIENCES.

A regular meeting of the Section was held on April 22d, with Professor Farrand in the chair. Professor Eberhardt Fraas, of Stuttgart, a corresponding member of the Academy, was introduced by Professor Osborn, and briefly addressed the meeting.

Mr. A. L. Kroeber presented some 'Notes on the Arapahoe Indians.' In this paper the social and ceremonial organization of these Indians was compared with that of other Plains Indians. On superficial examination various tribes appear to be organized according to identical principles, but fuller knowledge generally reveals differences among the similarities. From this it was concluded that such terms as gens, band, age-fraternity and dance-society have no stable or exact meaning and hence little descriptive value, detailed information being the great desideratum.

Professor C. H. Judd reported an experimental study on 'Practice in Visual Perception.' It is a generally recognized fact that an illusion grows weaker as the observer becomes more familiar with it. A quantitative determination of the disappearance of the illusion seen in the Müller-Lyer figure was the subject of the paper. Two series of results were reported, one from an observer who looked forward to the disappearance of the illusion, the other from an observer who did not know that the illusion would disappear and did not discover that it was disappearing. In both cases the illusion disappeared in about 1,000 observations. The curves of practice differ in form and show many details of effects of pauses. In the case of the first observer the effects of the practice gained in the first series was easily marked in all the additional series which were performed with other figures and with other positions of the first figure. In the case of the second observer the effect of the practice was in some cases positive, but in one case it was so decidedly negative that it exaggerated the illusion and prevented any disappearance of it through a series of 1,500 observations.

Professor E. L. Thorndike, in a paper discussing the 'Origin of Human Intellect,' proposed as a working hypothesis that the development of ideation and rational thinking in the human species was but an extension of the typical animal form of intellect. He defended this hypothesis by showing that mere increase in the number, delicacy and complexity of associations between sense-impressions and impulses might give concepts, feelings of relationship and association by similarity as secondary results, that in the human infant this seemed to occur and that down through the vertebrate phylum a clear evolution of the associative processes along these lines could be traced.

The last report of the evening was by Dr. R. S. Woodworth, on the 'Voluntary Control of the Force of Movement.' By recording simultaneously the force of a blow struck by the hand and the extent of the movement preliminary to the blow, it is possible to see how far the force is dependent on the extent. The results showed a certain degree of correlation between the two, but comparatively a slight degree. The inference was that the force of the movement was only partially and loosely dependent on the extent, and that the control and perception of the force of a movement were in

some measure a direct and independent function.

R. S. WOODWORTH,
Secretary.

SECTION OF BIOLOGY OF THE NEW YORK ACADEMY OF SCIENCES.

A REGULAR meeting of the Section was held on April 8th, Mr. M. A. Bigelow presiding. The following program was offered:

E. B. Wilson: 'The History of the Centrosomes in Artificial Parthenogenesis, and its Relation to the Phenomena of Normal Fertilization.'

F. S. Lee: 'Some Observations on Rigor Mortis.'

In continuation of his communication given at the December meeting, Professor E. B. Wilson presented the results of further studies on the development of the unfertilized eggs of *Toxopneustes* when treated by Loeb's magnesium chloride method. The principal points considered were the origin and history of the centrosomes and the general relation of the phenomena to those occurring in normal fertilization. Evidence was brought forward that the cleavage centrosomes of the primary division figure arise by the division of a single primary centrosome that is formed outside, but immediately upon, the nuclear membrane. As regards the chromatic transformation of the nucleus, two types of chromosome formation were described. In both cases a large nucleolus is formed, which attains a much greater size than in the fertilized eggs. In one type this nucleolus remains a plasmosome, or true nucleolus, which fades away at the time of division, the chromosomes arising nearly in the usual manner from the chromatin network. In the second type, the entire chromatic content of the nucleus is gradually accumulated in the nucleolus, which thus forms a chromatin-nucleolus, from which the chromosomes are afterwards derived nearly in the same manner as in *Spirogyra*. In regard to the accessory asters, or cytasters, it was shown that they contain central bodies often indistinguishable in sections from the centrosome of the nuclear figure, though in many cases less well developed. Sections demonstrate that the division of the cytasters is preceded by division of the central body, which draws out to form a central spindle in a manner similar to that described by MacFarland in the eggs of gasteropods. This fact, taken in connection with the physiological activities of the cytasters, seems to remove every doubt regarding the identification of the central bodies as true centrosomes. In comparing the phenomena in the magnesium eggs with those of normal fertilization, it was pointed out that the formation of accessory asters at the time of fertilization or cell-division is a widespread phenomenon. In normal fertilization or division, the accessory asters are of very transient character. In the magnesium eggs they attain a much greater development both structurally and functionally, but they are probably to be regarded as differing only in degree from those which appear during the normal process. In all cases, their disappearance is probably due to a concentration of the protoplasmic activities about the more active centers, connected with the nucleus, which alone survive to perform the normal functions of division. Evidence was adduced that the nuclear transformation occurring in normal fertilization is not primarily due to the union of the sperm-nucleus, or sperm-centrosome with the egg-nucleus, but to a general stimulus of the ovum effected by the entrance of the spermatozoon. Apart from the different character of the stimulus, this transformation of the egg-nucleus does not differ essentially from that taking place in the magnesium eggs. This is proved by the fact that in etherized eggs the egg-nucleus may undergo the karyokinetic transformation *without union with the sperm-nucleus or centrosome* — an observation which agrees with the much earlier results of O. and R. Hertwig on eggs treated with chloral hydrate. In normal fertilization this activity of the egg-nucleus is modified through its union with an active individualized sperm-centrosome, the presence of which inhibits the formation of an egg-centrosome such as occurs in the magnesium eggs.

Professor F. S. Lee stated that rigor mortis is characterized by a shortening of the muscles of the body, accompanied by a coagulation of the contents of the muscle cells. The nature of the phenomenon is disputed. Hermann has long insisted that it is analogous to muscular

contraction and is the final vital act of the dying muscle cell. In connection with his studies of muscle fatigue, the author, with Mr. C. C. Harrold, has made some observations on cat's muscle, which seem to contradict Hermann's conclusion. Fasting, which is characterized especially by a diminution of the free carbohydrates in muscle, hastens the on-coming of rigor mortis. The administration of the peculiar drug, phlorhizin, which eliminates both the free and the combined carbohydrates, has a similar but much more pronounced effect. On the other hand, the ingestion of grape-sugar by a phlorhizinized animal delays rigor. Hence the conclusion seems justified that the absence of carbohydrates is favorable, and their presence unfavorable, to the development of rigor mortis. As regards the ability of the muscle to contract, carbohydrates have exactly the opposite effect, their absence being unfavorable and their presence favorable. Hence, in this respect, contraction and rigor mortis are not analogous processes.

Henry E. Crampton,
Secretary.

SECTION OF ASTRONOMY, PHYSICS AND CHEMISTRY OF THE NEW YORK ACADEMY OF SCIENCES.

The section met on May 6th, at 8:15 P. M. The first paper of the evening was by Mr. C. B. Warring, entitled 'What Theology owes to Modern Science.' The paper was a very interesting interpretation of the Mosaic cosmogony in the light of modern scientific theories. The author defended the thesis that the order of events given in the cosmogony of Genesis did not necessarily contradict the order assumed by modern science. The paper was followed by a very interesting discussion.

The second paper of the evening, 'A Differential Astatic Magnetometer, suggested by Professor Rood,' was read by Mr. C. C. Trowbridge. The essential part of the instrument described is the suspension system, which consists of two groups of small magnets, set 23 cm. apart, rigidly connected by a fine glass fiber. The system is suspended by a single raw silk fibre 10 cm. long. By making the polarity of the two groups of magnets opposite, a system that is approximately astatic is obtained.

The object of the arrangement employed is partly to annul the effects of distant magnetic disturbing influences, such as those that arise from trolley car motors, etc., and partly to obtain a sensitive system that will act on the differential principle.

A magnet placed within a meter of the instrument and outside of the neutral plane between the two groups of magnets acts strongly on the nearest group, producing a deflection of the system.

The instrument was used in relative determinations of magnetic moments.

Mr. Trowbridge also gave a preliminary note on some experiments conducted by him on the influence of liquid air temperatures on the magnetization of steel and iron.

Magnets made from Crescent Co. and Sheffield magnet steels were chiefly tested.

The magnetic moment of bars magnetized at —186°C. and at 20°C. were found to be approximately the same, other conditions being equal. This was found to be true for both the steels mentioned.

Three Crescent steel bars magnetized at —186°C. were found to lose 38, 30.6, and 30.2, per cent. of magnetism when warmed to 20°C. A bar of this steel magnetized at 20°C. lost 9.5 per cent. of magnetism when cooled to —186°C.

These magnets after 9 days of approximately constant temperature at 20°C. were found to have further lost 6.1, 5.7, 8, and 12 per cent. of magnetism respectively.

Two bars made from Sheffield tungsten steel magnetized at —186°C. lost 12.2 and 15.7 per cent. magnetism when warmed to 20°C.

One bar of this steel magnetized at 20°C. lost 6.5 per cent. when cooled to —186°C.

A bar of Stubbs tool steel magnetized at 20°C. changed in magnetic moment, when cooled and heated between —186°C. and 20°C., as follows: at —186°m. —12.7; at 20° —30.5; at —185°, + 18 per cent.

Mr. Trowbridge stated that results similar to that found in the experiment with Stubbs steel have already been obtained by Professor Dewar.

F. L. Tufts,
Secretary.

TORREY BOTANICAL CLUB.

AT the meeting of the Club on March 10th, Dr. Marshall A. Howe discussed 'The Algal Genera *Acetabularia* and *Acicularia*' in the light of specimens recently collected by him in the Bermudas. One of the specimens he had identified as *Acetabularia Schenckii* Möbius by comparison with type material from Brazil. Since its original collection in Brazil the species has been found, according to Count Solms-Laubach, on the island of Curaçoa, off the Venezuelan coast, and also in Guadaloupe, but its occurrence now in Bermuda, about a thousand miles further north, is a point of some interest. The aplanospores in this species surround themselves each with a thick calcareous shell and these shells adhere so that on the decay of the sporangium wall the spores are left in a single coherent mass. On this ground, Solms-Laubach refers *Acetabularia Schenckii* to the fossil genus *Acicularia*, hailing it as the only known living species. The generic separation from *Acetabularia* was thought by Dr. Howe to be defensible, but doubt was expressed as to the nature of *Acicularia pavantina*, the fragmentary fossil on which the genus *Acicularia* was established. Efforts are now being made to secure this *Acicularia* type for examination. With the aid of material preserved in formalin, stages in the development of the disk of both *Acicularia Schenckii* and *Acetabularia crenulata* were followed out which have been observed hitherto only in *Acetabularia mediterranea* and more completely in some respects than have been recorded for this species. This complete series of developmental stages of the disk seems to confirm, with much certainty, the morphological explanation of the disk put forward by Solms-Laubach in 1895. The disk as a whole is evidently not a complex aggregate of primary 'leaf-whorls' or primary whorls of sterile branches, as is taught by Wille in 'Die natürlichen Pflanzenfamilien' and by others, but is to be homologized with a single primary whorl of sterile branches, as has been suggested somewhat tentatively by Count Solms-Laubach. A point of some biological interest is found in connection with the aplanospores of *Acicularia Schenckii*, the walls of which are provided with a circular lid or operculum to permit the escape of the zoogametes. As the spores lie embedded in the calcareous massula the lid is always turned toward its surface and is but slightly, or not at all, incrusted with lime. It is expected that Dr. Howe's paper will be published in full in an early number of the *Bulletin*.

The second paper, by Mrs. E. G. Britton and Miss Alexandrina Taylor, was on the life-history of *Schizaea pusilla*, *Lygodium palmatum* and *Vittaria lineata*. Living and pressed specimens were shown of all three; also microscopic preparations and drawings illustrating the gametophyte from the spore to the sporophyte in the various stages of development. For *Schizaea pusilla* the exhibit of the life-history was very complete, and the descriptions and plates have already been published in the *Bulletin* of the Torrey Botanical Club for January, 1901. In *Lygodium palmatum* the development has been slow. During the winter, in the laboratory, the spores have germinated and formed an irregular protonemal growth, finally perfecting their normal prothallia, which are spatulate and bifurcated at apex. Thus far no antheridia or archegonia have been found. Of *Vittaria lineata*, fresh material was received from St. Augustine, Florida, early in February and a complete series of slides and drawings secured, showing a much branched thallus, bearing gemmæ at the extremities, as described by Goebel in certain East Indian species. The gemmæ were found bearing antheridia, radicles and young prothallia, evidently serving the double purpose of a sexual reproduction and cross-fertilization. The sporophyte in its young stages was also studied and the structure and venation worked out. Pressed specimens, named *Vittaria lineata*, were shown from the herbarium of Columbia University, which had been compared with Fee's monograph of the genus. Many of these were found to be incorrectly named as a comparison of the spores, sporangia and bracts at the base of the leaf proved.

Professor Underwood commented on the Linnean treatment of the *Vittarias*, and their subsequent mutations.

Professor Millspaugh, of the Field Columbian Museum, Chicago, spoke briefly on the results

of a recent trip to the West Indies for the purpose of studying the economic fruits of the tropics.

D. T. MACDOUGAL,
Secretary pro tem.

DISCUSSION AND CORRESPONDENCE.

BIBLIOGRAPHY OF GEODESY.

TO THE EDITOR OF SCIENCE: In the Report of the United States Coast and Geodetic Survey for 1887 there was published a Bibliography of Geodesy. Since the date named so many important contributions have been made to the literature of this subject that during the last meeting of the International Geodetic Association a resolution was passed requesting the undersigned to prepare a new edition of the Bibliography.

This work is now well under way, and every possible effort will be made towards making it complete. This desirable end can be attained only with the assistance of those authors who are good enough to send as soon as possible titles of their publications to the address given below.

As in the first edition, it is proposed to include all papers, books and reviews, pertaining to geodesy, least squares, figure of the earth, density of the earth and gravity determinations, including theoretical discussions of the pendulum.

In complying with this request, authors should give:

1. Full name.
2. Complete title.

a. If book, give size, number of pages in preface and in body of book, number of plates and illustrations, date and place of publication.

b. If in a serial publication, give name of publication, volume, and year and pages occupied by the contribution.

c. If a review, state the title of work reviewed.

In case the work has been reviewed, give name of reviewer and where the review may be found.

If preferred, in order to insure harmony in the form of making out the titles, publications may be sent to the undersigned. The International Exchange Service of the Smithsonian Institution has graciously consented to transmit such works as may be forwarded with the object named in view. They should be sent in my name to the Smithsonian Institution, Washington, D. C.

By giving this their early attention, author will confer a favor upon the compiler and upon those who may find it necessary to consult the work when published.

J. H. GORE.

COLUMBIAN UNIVERSITY,
WASHINGTON, D. C.

SHORTER ARTICLES.

NOTE ON THE WESTERN TERTIARY.

THE recently published discussion on 'The Freshwater Tertiary Formations of the Rocky Mountain Region,' * by Professor W. M. Davis, in which he indicates published evidence to prove those supposed lacustrine deposits not to have deposited in large lakes, but rather in regions of lakes and rivers, explains well the Eocene deposits which I have seen in northwestern Wyoming in the Bighorn basin. This region was visited by a party from the University of Minnesota in the summer of 1899.

The Eocene badlands there show an extent of horizontal strata which, when viewed as it is exposed for miles around one, does suggest at once a large filled lake basin. But there is a rapid alternation of clay and sand strata, and the several diverse kinds observed recur so unequally, and yet often so monotonously that the theory of a large permanent lake does not suffice to explain the phenomena. In fact while exploring for fossils I had the impression that we were not beyond the supposed lake's marginal zone, even when 40 miles or more from the formational boundary, and came finally to believe that this freshwater Tertiary might be different from others of the West. Professor Davis's argument now convinces me that it is not.

In order to find fossils rapidly one had to search out what we called rivers and bogs. The former are shallow trough-shaped beds of sand occurring either as intercalated masses or as thickened parts of a regular stratum. The bogs occurred here and there, more or less

* *Proceedings Am. Acad. Arts and Sci.*, Vol. XXXV., p. 345.

clearly indicated by color and by small rough clay-iron residuum when weathered. Fossils occurred most frequently in those deposits and one became aware of their discontinuity when trying to follow them in search of their contents. The sand troughs or rivers yielded the whole bones, *i. e.*, vertebræ with processes and even rarely whole skeletons. The bogs yielded fragmentary bones. These were found to have been gnawed, as a rule, and the gnawing had been done also where they now lie in the strata. Legs were found bitten off at the knees, as if the animal had mired and its buried parts thus escaped being devoured. Also numerous fragments of, evidently, a single animal would occur scattered about, the ends and thin parts of bones being gnawed off. For example, more than once a Coryphodon's large tooth was found with the surface, including the enamel, chiseled off by some corrugated tooth, probably that of some Tillodont mammal. Plates of turtles' plastron had likewise been nibbled all around their margins. In fact, worthless fragments composed the greater part of the fossils.

When one had become skilled in detecting the differences between those pieces fractured before, and those after, fossilization, many strange things began to be evident, such as fragments taken from the same stratum at some distance apart, proving to be those of one bone; and again fragments representing the same parts of several animals occurring in one spot, the other parts of all being absent. A lot of molar teeth and an odontoid process seem often to represent a head and neck. This all appeared to be incidental to the feasting that had preceded fossilization.

That crocodiles and turtles may have done the gnawing in part was suggested by their fossil remains, but that the chiseling process was theirs could not be maintained. In some cases, maceration had left the bones shapeless or thickly encrusted with iron. And this maceration as well as the chiseling might well argue the subaerial deposition of the bones.

I may mention also two geologically significant phenomena which require close observation to distinguish them. Original stratigraphic inequalities, amounting sometimes to local unconformability, might be passed unnoticed among the numerous similar looking inequalities due to unequal induration of the rock, the latter being intimately associated as to its cause with the physiographic changes now developing. And the color banding may be both original stratigraphic and secondarily modified. I remember one fine example of a large trough filled with a series of clay and sand strata, seen at a distance on the left of the trail ascending Tatman's butte to the Buffalo basin. But not having had time to examine it minutely, I scarcely dare assert that it might not be secondary cross-coloring. Close at hand one would not have noticed it, because the whole could not have been seen, and the slow thinning out of individual strata would be nothing unusual. Expeditions into badlands for the purpose of collecting fossils can not well take time in one season to gather and verify occurrences sufficient to prove the exact geologic nature of the deposit of part, much less the whole, of a basin, which, however, expeditions for that express purpose might do.

FREDERICK W. SARDESON.
UNIVERSITY OF MINNESOTA,
April 6, 1901.

AN UNUSUAL TYPE OF AURIFEROUS DEPOSIT.

ONE of the most unique deposits of gold-bearing material which the writer has ever seen has been worked during the past three or four years at the King Solomon mine. It is situated near the summit of Cañon mountain, in the basin of the South Fork of Salmon river, in the southwestern part of Siskiyou county, California.

The ore consisted of a body of semi-decomposed country-rock, including micaceous schist, slate and greenstone, heavily stained with the oxides of iron and manganese and containing fine particles of free gold disseminated through it. The deposit had a length of about 500 feet, an average width of 60 feet and mainly a workable depth of 50 feet, although a much narrower body of ore continues to greater depth. Mining operations have been conducted in several large open pits, beneath the floors of which have been excavated tunnels. The ore is shoveled from the loose crumbling slopes of the pits into

barrows, then wheeled and dumped through chutes in the floor, and hauled out of the tunnels in cars.

Along certain narrow streaks the ore was of good grade, carrying values as high as several hundred dollars to the ton; but it has been the policy of the company to work the deposit on a large scale and in a cheap manner; hence, everything has been removed which contained sufficient gold to pay a small profit. In this way the average yield per ton of the ore was, during the first few years, brought down to $7 and even $5 in gold and later this was further decreased to $3.50. From month to month the ore showed a remarkable uniformity in tenor, although but 40 to 70 tons were handled per day, and this was taken haphazard within the limits of what was determined to be the ore-body.

Running through the center of the deposit, and parallel with its major axis, there was a narrow dike of white acid porphyry, such as is commonly associated with gold-bearing veins of this region, and the entire ore-body has frequently been reported as a mineralized dike. However, the acid dike is not ore, but is thrown away as waste. On both sides the ore-body extended away from it to a distance of 20 to 50 feet and terminated irregularly in the mass of the decomposed rock, there being no well-marked walls or other evidences of common vein action. The grade of the ore was closely connected with the intensity of the iron stain and particularly with the quantity of brown manganese oxide present.

At first thought, this large deposit of red, soft, decomposed rock carrying free gold was considered the upper or oxidized portion of a zone of impregnation of auriferous sulphides such as are rather common in this northwestern California region; but a consultation with the superintendent of the mine, Mr. F. N. Fletcher, brought to light some facts which demonstrate that it is certainly of an entirely different character. It is unique among deposits of this country in the following two points:

1. It is absolutely free from any traces of pyrites changed to limonite such as are always found in panning the surface portion of other veins.

2. It does not present any evidence of passing in depth into a shear zone modified by solfataric action and impregnated with auriferous sulphides.

Upon first arrival at the mine, the writer was impressed by the marked resemblance in the tint and character of the deep red staining to those of certain accumulations of residual red clay found frequently in hollows in the surface of limestone formations, as, for instance, over the Galena limestone in the Mississippi basin. This suggested an explanation for the origin of the deposit which was subsequently worked out as follows:

The site of the King Solomon mine, which is at present the top of a mountain ridge, was once the bottom of a rather deep, broad basin eroded by subaerial agencies from a series of quartzites, black slates and limestone. This series was intersected by numerous narrow branching dikes of greenstone. Evidence that a small amount (say a trace) of gold was a primary constituent of this system of eruptives has been found in different parts of this country.

The carbonated meteoric waters circulating laterally and downward beneath the slopes of the basin, dissolved gold out of these greenstone dikes and carried it, along with iron and manganese salts (derived from pyrites in the quartzites and slates), to the center of the basin, where, just beneath the surface, these minerals were precipitated as free gold, ferrous carbonate or hydrous ferric oxide and some salt of manganese, perhaps the last in its present form of oxide. Precipitation was probably due, as in the case of limonite and wad in bogs, to the decreased circulation of the water at the center of the basin, and in part also to the water rising close to the surface and becoming subjected to the oxidizing influence of the atmosphere.

Subsequently, through great erosion of the region, the water level was depressed in the strata, the basin no longer existed, and the limonitic deposit worked downward, penetrating to unequal depths in different places. The porous schists and slaty rocks were deeply stained with the oxide and impregnated with gold, but the acid dike in the center of the deposit was largely impervious to the solution and escaped heavy mineralization.

In short, the King Solomon ore-body has had a mode of formation roughly analogous with that of the limonite ore deposits of the Great Valley of the Appalachian region, and of the limestone regions of southern Missouri. Such accumulations of ferruginous matter as the result of deposition from waters of ordinary surface temperature, and circulating within several hundred feet of the surface of the earth, are of common occurrence in many parts of the world, and may be found in other sections of northwestern California, but they are not often auriferous to an appreciable extent. It is its gold contents which make this King Solomon deposit so remarkable.

To the writer, the scientific interest of the preceding facts appears to be in their bearing on the question of the power of ordinary subsurface waters to dissolve and redeposit gold under conditions not favorable to the production of iron pyrites. We seem to have here a clear case where metallic gold has been put through the same process of solution, concentration and precipitation as has the staining material, the oxides of iron and manganese.

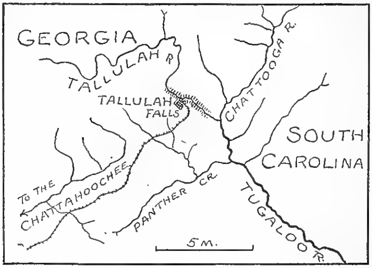
OSCAR H. HERSHEY.

BERKELEY, CALIF., Jan. 20, 1901.

CURRENT NOTES ON PHYSIOGRAPHY.

TALLULAH GORGE, GEORGIA.

THE studies of Hayes and Campbell on the southern Appalachians have made us familiar with the general features of a contested drainage area in northeastern Georgia, where the headwaters of the Savannah (Tugaloo) river are capturing those of the Chattahoochee. Some further details of the changes thus effected are described in a brief essay on 'the Geology of the Tallulah Gorge,' by S. P. Jones (Amer. Geol., XXVII., 1901, 67–75). The gorge is narrow, steep-sided, and over 500 feet deep; the river flows through it in a succession of cascades and rapids; it is evidently a young river course. The precise order of events in the development of the gorge does not appear to have been made out; indeed the author here cited does not seem entirely convinced of the process of capture as an efficient cause for the new order of things. Yet it is certainly significant that the gorge, unusual if not unique in sharpness of form among the southern Appalachians, should occur in immediate association



with a group of features whose systematic relations would seem to point unequivocally to the invasion of one river basin by the head branches of another.

In view of the open form and gradual descent of the Chattooga valley in contrast to the narrowness of the Tallulah gorge and the rapid descent of the river through it, one may reasonably conclude that the first was captured much earlier than the second. This makes it seem probable that the Tallulah formerly followed a course near the railroad line, and that its entrance into the Chattooga is the result of diversion by the headward growth of a creek on the line of the gorge; although a somewhat different opinion is expressed in the article here abstracted.

PREHISTORIC LANDSLIDES IN THE ALPS.

CERTAIN Alpine valleys contain huge accumulations of mountain waste, described as moraines by earlier observers, but now interpreted as landslides (see SCIENCE, II., 1895, 618). The latest special study on this subject is by J. Oberholzer ('Monographie einiger prähistorischer Bergstürze in den Glarner Alpen,' Beitr. Geol. Karte der Schweiz, n. f., IX. Lief., Bern, 1900). It discusses a number of large prehistoric slides in the neighborhood of Glarus, giving abundant details as to structure, source, path, volume, etc. A colored map, 1 : 20,000, shows the geological formations of the district in the slides as well as in the mountains. Some of the slides still bar their valleys and hold back lakes;

others have been trenched by streams. All show more or less distinct changes of form by weathering and washing (especially where torrent fans are built upon them), although generally retaining something of the tumult of surface that characterizes recent slides. One of the slides (that by Schwanden in the Linththal) has a small amount of morainic material strewn over its surface, as well as more abundant moraine beneath it; and from this Oberholzer concludes that it occurred during the last interglacial epoch. But inasmuch as its surface is still very uneven, it can hardly be believed that it has been overridden by more than a small and short-lived glacier.

No reference is made to the suggestion, which is certainly gaining ground among Swiss observers, that the landslides of the class here described result from the oversteepening of the basal slopes of valleys that have been overdeepened by glacial erosion.

THE GREAT AFRICAN LAKES.

THE peculiar likeness of the fauna of Lake Tanganyika to marine forms has prompted a special study of the Great African Lakes by an expedition under the direction of J. E. S. Moore, whose report contains matter of much value (Tanganyika and the countries north of it. Geogr. Journ., XVII., 1901, 1–35).

North of Tanganyika, the floor of the great rift valley or *graben* in which the lakes lie rises to form a strong barrier which once constituted part of the divide between the Congo and the Nile drainage systems. But now a group of large and active volcanoes some 50 miles further north, one of which is 13,000 feet high, have built a second barrier on the valley floor, thus cutting off the basin of Lake Kivu from that of Albert Edward Nyanza, and raising the former nearly 2,000 feet. That Kivu was once tributary to the Nile is clearly shown by its fauna, which is in nearly all respects identical with the normal fresh-water lake fauna of the Nyanzas to the north; but its outlet, Rusisi river, now flows south with many cataracts over the rocky swell in the valley floor, thus connecting Kivu with Tanganyika; and it is evidently since this connection was made that a fish characteristic of the Congo basin has reached Kivu. The rift valley, the active volcanoes far inland, the great lakes and their peculiar fauna combine to make this a region of remarkable interest.

W. M. DAVIS.

RECENT PROGRESS IN PALEONTOLOGY.

CONGESTION OF MUSEUMS.

IT is very important that the various museums of the country should receive special funds with which to work up the collections of vertebrate fossils that are rapidly accumulating. Much more time is required in preparing a fossil than is spent in collecting and shipping it from the field. The result is that all the museums of the country which have been collecting during the past few years are greatly congested with material. According to a moderate estimate, from five to fifteen years of constant work must be spent upon the collections now in each of our museums. The delay in working up fossils of various types threatens to cause serious inconvenience and delay in the matter of publication. Even highly trained preparators are unable to prepare a fragile fossil rapidly. Some single dinosaur vertebræ, for example, are so broken that from a month to six weeks must be spent upon them. The collections which have already been made in the West fill thousands of boxes, and the most welcome gift which could be made to any of our museums would be a gift especially for the purposes of preparation.

SPECIAL INVESTIGATIONS.

A GRATIFYING division of labor is in progress among the vertebrate paleontologists of the country. In Kansas University, Professor Williston is beginning a very careful study of the Plesiosaurs, which will form a sequel to his admirable memoir upon the Mosasaurs. In the University of California, Dr. Merriam is making a special examination of the John Day fauna. In Yale University, Dr. Wortman is thoroughly revising the rich collections made in the Eocene or Bridger beds, and will publish a series of papers illustrating Professor Marsh's principal types. In the American Musuem, Dr. Hay is especially studying the fossil Chelonia of the American Museum and Cope collections; Dr. Matthew is making a study of the Creodonts of

the Miocene fauna of Kansas and eastern Colorado, of which much remains to be done; Mr. Gidley is working upon the Pleistocene horses, and has just completed a very careful revision of the species; Dr. McGregor is working upon Belodon and the Phytosauria, comparing the American and German types; Professor Osborn is especially studying the Titanotheres. At Princeton, Professor Scott is working up the Patagonian mammals. In the Carnegie Museum, Mr. Hatcher has just completed a memoir upon Diplodocus.

EVOLUTION OF THE HORSE.

A FRIEND of the American Museum of Natural History has recently presented a fund, which is to be used exclusively for the collection, exhibition and study of the fossil horses of America. Professor Osborn has planned two expeditions for the coming season, with the especial object of filling gaps in the already rich series. It is proposed also to mount as complete a series of fossil skeletons as possible, showing all the chief stages in the evolution of the horse from *Hyracotherium* to *Equus*. Four complete skeletons have already been procured, two of which have been mounted. It is also proposed to exhibit recent types of skeletons, showing the effects of artificial selection. H. F. O.

AN ARCHEOLOGICAL MAP.

BENEDICT'S map of Chain-O'-Lakes, near Waupaca, Wis., copyrighted by F. M. Benedict in 1896, although not well known, is yet of considerable value and interest to archeologists. It locates the Wisconsin and Wolf River Indian trail, and by numbers indicates village sites, a bake hole, kitchen middens, graves, and conical, ovals and effigy mounds.

The location and description of such remains, however brief, are always valuable. The great number of archeological sites, and the comparative ease with which they could now be located and described, seem to cause local students to ignore the great need of present work in this line. They do not realize that the facilities for the work at the present time are far better than they will be a few years hence, when but a fragment of the same results could be accomplished. Mounds plowed over are harder to find, and crops ruined by the excavations of the explorer are more expensive than anything injured on wild land. Permission of owners is also harder to secure in more thickly settled regions. In this connection Mr. Benedict's efforts certainly are commendable.

It is very desirable that such a map be constructed by every local student or lover of archeology, until every county in the country is covered. It might be saved for future use either by being published or by filing duplicate copies of it in several libraries or museums. Certainly specimens found by such students deserve a careful record and preservation in the nearest substantial public museum or college.

HARLAN I. SMITH.

THE BIOLOGICAL STATION OF THE UNIVERSITY OF MONTANA.

THE Biological Station of the University of Montana will be open for its third season beginning July 22d, for four weeks. The laboratory is near the P. O. of Holt, Montana, at the northern end of Flathead Lake, and from it a great variety of collecting grounds is easily accessible: Flathead Lake is 32 miles long and 16 wide, with an elevation of 4,000 feet; Swan River debouches into the Lake near the station, and numerous other large and small streams, swamps, smaller lakes, forests and mountains with an altitude of ten thousand feet offer a variety of conditions not within reach of many similar institutions.

Courses in zoology, botany, ornithology and nature study will be offered. A small party will leave Missoula early in June and will make explorations in the Cabinet or Mission mountains, reaching the Laboratory at the beginning of the sessions.

The facilities of the station which are placed at the service of students and investigators embrace a gasoline launch, row-boats, botanical apparatus, insect nets, pumping apparatus, etc., and a team and wagon equipped with camping outfit.

The New York Botanical Garden will cooperate in the botanical work of the Station. Dr. D. T. MacDougal, director of the laboratories in that institution will join the party in

the field for the purpose of making collections, and pursuing some investigations upon the relations of climate and vegetation, and will continue both lines of work at the Station; the botanical work during the season will be under his guidance. Attention will be given to general botany, and to the special features of the flora of Montana. Mr. R. S. Williams, of the same institution, will spend the month of June in making collections in the northwestern part of the State, and will be present during a part of the session, giving especial attention to mosses and ferns.

No tuition fees are charged either to students or investigators; microscopes and glassware are supplied free, but the worker is expected to meet the cost of material actually consumed.

Applications and correspondence should be addressed to the Director, Professor Morton J. Elrod, Missouli, Mont., until July 10th; after this date to the Biological Station, Holt, Flathead Co., Mont.

SYNTONIC WIRELESS TELEGRAPHY.

At a meeting of the Society of Arts, on May 15th, Mr. Marconi read a paper on 'Syntonic Wireless Telegraphy.' In the course of his paper, according to the report in the London *Times*, he gave an account of two methods by which he has been able to arrange a selective action in his instruments, so that, for example, two stations can converse with each other without being overheard by an intermediate one. In the first he employed an ordinary vertical radiator placed near an earthed conductor, the effect of the latter being to increase the capacity of the radiating vertical wire without increasing its radiative power; in this way syntonic results were obtained without difficulty. In one form of this arrangement the radiating and resonating conductors consisted of a cylinder, the earthed conductor being placed inside. Using cylinders of zinc only seven meters high and 1½ meters in diameter, good signals were obtained between St. Catherine's Point and Poole (50 kilometres distance), which were not interfered with or read by other wireless-telegraph installations at work in the immediate vicinity. The closely adjacent plates and large capacity of the receiver caused it to be a resonator with a very decided period of its own, and, therefore, it was not apt to respond to frequencies differing from its own period, or to be interfered with by stray ether waves, such as were sometimes caused by atmospheric disturbances, and occasionally proved troublesome in the summer. His second syntonized system was the outcome of experiments with the discharge of Leyden jar circuits. Taking for granted that the chief difficulty with the old system lay in the fact that the oscillations were very dead-beat, he tried, by associating with the radiator wire a condenser circuit known to be a persistent oscillator, to set up a series of persistent oscillations in the transmitting vertical wire. In one application of this principle the vertical conductor was connected to earth through the primary of a transformer, the secondary of which was in circuit with the coherer, and, in order to make the tuning between these two circuits more marked, an adjustable condenser was placed across the coherer. To obtain the best results, it was necessary that the free period of electrical oscillations of the vertical wire primary of the transformer should be in electrical resonance with the secondary of the transformer which included the condenser. It was easy to understand that, if there were several receiving stations, each tuned to a different period of electrical vibration, of which the corresponding inductance and capacity at the transmitting station were known, it would not be difficult to transmit to any one of them without danger of the message being picked up by the others for which it was not intended. But, further, it was possible to connect to the same vertical sending wire, through connections of different inductance, several differently tuned transmitters, and to the receiving vertical wire a number of corresponding receivers; then different messages could be sent by each transmitter to the radiating wire simultaneously, and received simultaneously by the vertical wire connected to differently tuned receivers. A further improvement had been obtained by the combination of the two systems described in the paper, the cylinders being connected to the secondary of the transmitting transformer and the receiver to a properly tuned induction coil, with

all the circuits tuned to the same period. The fact that signalling had been successfully carried out over a distance of 50 kilometers with a cylinder only 1.25 meters high and one meter in diameter led to the possibility of constructing portable apparatus for use in the field. He had designed a complete installation on a steam motor-car, on the roof of which was placed a cylinder, only six or seven meters high, that could be lowered while traveling. By means of this, communication had easily been carried on with a syntonized station 50 kilometers distant, a 25-cm. spark induction coil, taking about 100 watts, being used for transmitting. A strip of wire netting dragged behind the car was sufficient for earth connection, or in lieu of any earth connection the electrical capacity of the boiler might be utilized. As to the distance over which signalling had been effected, last spring he established a station at the Lizard and opened communications with St. Catherine's—a distance of over 300 kilometers. The amount of energy used in this case was not more than 150 watts, and the aerial conductor consisted of four parallel vertical wires $1\frac{1}{2}$ meters apart and 48 meters long, or of a strip of wire netting of the same length. In conclusion, Mr. Marconi gave some examples of the progress made in the practical utilization of his system, and also briefly examined a method proposed by Professor Slaby.

WIRELESS TELEGRAPHY IN THE NAVY.

ADMIRAL BRADFORD, chief of the naval bureau of equipment, has given out the following extract from the report of the board which has investigated the question of transmitting messages by wireless telegraphy:

"From the examination of the subject, as outlined in the orders of the department, the board makes the following recommendations:

"1. That the use of homing pigeons be discontinued as soon as wireless telegraphy is introduced into the navy.

"2. That, pending such action, no new pigeon codes be established.

"3. That wireless telegraphy be adopted by the navy for transmission of messages between distant points.

"Referring to the last recommendation, the board is of the opinion that a high degree of special electrical training is demanded for the successful operation of any system of wireless telegraphy, and it therefore suggests as necessary the establishment of two stations sufficiently far removed from each other for the training of officers and men.

"In its opinion this requirement would be best met by the establishment of such stations at the Navy Yard, Washington, and the Naval Academy, Annapolis. If wireless telegraphy fulfills what now seem to be its possibilities, the cadets should be thoroughly trained in it.

"As the investigation made by this board is not technical, there being no apparatus of any kind ready for test, but general in its character, such partial examinations as outlined above would not change the recommendations already made.

"The selection of any special system of wireless telegraphy is, in the opinion of the board, very largely a matter of business detail.

"If for any reason any competitive test of different systems is thoroughly desirable the board recommends, in view of the fact that the improved Marconi apparatus will not be available for several months, and that improvement in other systems may occur in that interval, that it be made only after due notice and preparation therefor, and by a special board of experts appointed for the purpose."

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

ARRANGEMENTS for the Denver meeting of the American Association for the Advancement of Science are locally assuming very definite shape. A meeting of the Colorado Science Teachers Association was held in Denver on May 11th and all the members of the American Association residing in Colorado were invited to attend, a special point being made in the call that the meeting would consider the August meeting of the American Association. The cooperation of the Society was pledged to the Local Executive Committee, and the committee itself was organized by the election of Mr. George Lyman Cannon as chairman and Mr. Arthur Williams, secretary of the Chamber of Commerce and Board of Trade, as secretary.

Mr. Jas. F. Callbreath, Jr., editor of the *Mining Reporter*, was appointed chairman of the committee on printing and will at once proceed to publish the Preliminary Announcement, which will be distributed to all members of the Association.

The permanent secretary has as yet been unable to secure definite information regarding the railroad rates. This is the first time the Association has met in the far West and all the passenger associations are holding their decisions contingent upon that of the Western Passenger Association, in whose territory the meeting is to be held. This association is not in the habit of taking definite action on meetings of this character until within 60 days of the meeting, and this has complicated the railroad question. The peculiar character of the Association, in that it is composed so largely of men connected with college faculties, who have a long summer vacation and desire to make their plans well in advance, and, in fact, the majority of whom leave home after commencement and are difficult to reach by mail, has been shown to the railroad people and a speedy decision is hoped for. The permanent secretary thinks it most probable that a rate of not to exceed one fare plus $2 will be secured for the territory west of Chicago, and surely the passenger associations east of Chicago will make a rate at least as low as one fare and one-third. An effort is still being made to secure a one-fare rate for the entire trip.

SCIENTIFIC NOTES AND NEWS.

PROFESSOR WILLIAM JAMES, of Harvard University, began his course of Gifford Lectures at Edinburgh on May 16th.

THE Paris Academy of Sciences has elected Dr. Zeuner, of Dresden, a correspondent in the section of mechanics. The other nominations were: Professor Henry T. Eddy, University of Minnesota and Professor Zabousdsky, of St. Petersburg. In the section of geography and navigation, Dr. Oudemans, of Utrecht, was elected correspondent. The other nominations were: Mr. Wharton, of London, Professor Albrecht, of Potsdam, and Professor Neumayer of Hamburg.

THE following have been elected honorary members of the American Chemical Society: Professor William Ramsay, University College, London, Sir Henry E. Roscoe, University of London, Professor Emil Fischer, University of Berlin, Professor Adolph Baeyer, University of Munich, and Professor George Lunge, University of Zurich.

SIR WILLIAM MACCORMAC, president of the Royal College of Surgeons, London, has been elected a foreign associate fellow of the College of Physicians of Philadelphia.

MR. WILLIAM WHITWELL has been elected president of the British Iron and Steel Institute in succession to Sir William Roberts-Austen.

MR. W. LANGDON has been nominated for the presidency of the Institution of Electrical Engineers, London.

THE Linnean Society, London, has awarded its gold medal to Lieutenant Colonel Sir George King, the botanist, lately superintendent of the Royal Botanic Garden at Calcutta. He has published important monographs on the flora of India, China and the Malay Peninsula.

THE Bessemer Gold Medal of the British Iron and Steel Institute has been conferred upon Mr. John Edward Stead, F.I.C., in recognition of the value of his investigations of the physical and chemical properties of iron and steel.

DR. G. T. MOORE, of the department of biology at Dartmouth College, has been appointed algologist in the Department of Agriculture.

Nature states that news has been received of the safety of Professor W. Baldwin Spencer and Mr. Gillen. They report themselves in good health and already busy taking phono- and kinematographic records. The Postmaster-General of South Australia has provided them with pocket apparatus for tapping the overland telegraph line when in the vicinity of their route.

THE president of the University of Tokyo, Deiroku Kikuchi, will represent Japan at the bi-centennial celebration of Yale University next October.

KING EDWARD VII. has consented to be patron of the British Medical Association.

A DEPARTMENT of experimental psychology has been established in connection with the Pathological Laboratory of the London County Council Asylums at Claybury. Dr. W. G. Smith, recently of Smith College, Northampton, has been placed in charge.

DR. OTTO LUGGER, State entomologist of Minnesota, died of pneumonia on May 21st. Dr. Lugger was an entomologist of wide reputation. He was assistant to the late Professor C. V. Riley at the time when the latter was publishing his well-known 'Reports on the Insects of Missouri.' Subsequently he became curator of the Maryland Academy of Sciences and, still later, an assistant in the Division of Entomology, U. S. Department of Agriculture, from which place he went to Minnesota as State entomologist in 1887. The latter office he has held for nearly 14 years with great success. His reports have been models of their kind and his investigations along certain lines have been of great value to agriculture.

DR. WILLIAM D. THOMAS, professor of psychology in Richmond College, Va., died on May 22d.

THE death is announced of Dr. E. Bretenschneider at St. Petersburg. He was for many years physician to the Russian Legation at Pekin, and made important researches on Chinese archeology, geology, etc. His books include two on Chinese botanical work.

THE death is also announced of Dr. Peter Helmling, formerly professor of mathematics at the University of Dorpat, at the age of eighty-four years, and of Dr. George Asp, professor of anatomy at Helsingfors.

The officers of Section C, Chemistry, of the American Association have issued the following preliminary announcement:

The 50th annual meeting of the American Association for the Advancement of Science will be held in Denver, Colorado, August 24-31, 1901. The meetings of Section C will be held as heretofore in connection with the meetings of the American Chemical Society. The officers of the Section ask the cooperation of all the members in making the meeting a successful one. To this end you are personally requested to present one or more papers. Will you kindly fill out and return the enclosed blank giving us information as to whether you expect to attend the meeting; also the titles of any papers which you will present. According to the constitution, such abstracts of the contents of the papers as will give a general idea of their nature must be sent to the Secretary of the Section as early as possible. If you cannot present the abstract at this date, kindly send the title of the paper and furnish the abstract later. It is hoped to have reviews of the recent progress made in the various fields of chemistry. The presentation of such reviews by any of the members will be greatly appreciated. The officers of the Section will also appreciate any suggestions in reference to the program.

WILLIAM MCPHERSON,
Secretary of Section C.

OHIO STATE UNIVERSITY,
COLUMBUS, O.

THE American Microscopical Society will meet at Denver, in conjunction with the American Association for the Advancement of Science, on August 20, 30 and 31. The Secretary, Professor Henry B. Ward, of the University of Nebraska, promises that the meeting will be the best and most enjoyable yet held.

THE Council and Board of Directors of the American Chemical Society have authorized the expenditure of $500 for the publication in a separate volume of the proceedings of the twenty-fifth anniversary meeting of the Society, held last month.

IN addition to the civil service examinations that we have already announced for June 3d, there will be two others: that of secretary of the National Bureau of Standards, with a salary of $2,000, and that of field assistant in tree-planting in the Division of Forestry, with a salary of $1,000. On June 18th examinations will be held as follows: assistant ethnologist in the Bureau of Ethnology, at a salary of $1,200; zoological clerk in the Bureau of Animal Industry, at a salary of $840; a botanical clerk and assistant in the Department of Agriculture, at a salary of $1,000, and a special statistical compiler, Department of Agriculture, at a salary of $720. Those desiring further information concerning these positions should apply to the Civil Service Commission, Washington, D. C.

TWO buildings for the Pacific Botanical Station, which is being established by the botanists

of the University of Minnesota, are in process of erection at a cost of about $2,500. The British Columbian Parliament has passed a grant for the construction of a road between the Port Renfrew dock and the Station site on the Straits of Juan de Fuca. A party of thirty or forty western botanists will leave Minneapolis under the direction of Professor Conway MacMillan and will spend the latter part of June and the first two or three weeks in July in the study of marine vegetation at the new seaside station, and of mountain vegetation at Banff, Alberta, and Field and Glacier, British Columbia. A subordinate party proposes to explore some of the little-known mountains of northern Vancouver.

We learn from the *Botanical Gazette* that the valuable herbarium of the late Professor Agardh has been secured by the University of Lund.

Mr. L. Cockayne, of Tarata, New Zealand, has recently presented to the New York Botanical Garden a large number of seeds of plants indigenous to the island, and has also donated nearly a hundred fine photographs, showing distinctive features of the vegetation of that island and also of Chatham Island, which he has explored within the last year.

The collection of Indian relics and prehistoric anthropological specimens collected by Andrew E. Douglass has been presented to the American Museum of Natural History, New York. It contains about 23,000 specimens which were selected with great care.

The collection of butterflies of the American Museum was opened to the public on May 24th. There are about 5,000 specimens, including the valuable collection given some time since to the Museum by the Rev. E. A. Hoffman.

The library and collections of the late Dr. Jared P. Kirtland have been placed in the custody of Adelbert College by his granddaughter, Mrs. Caroline P. Cutter. Dr. Kirtland was a pioneer naturalist of the Western Reserve, the founder of the Kirtland Academy of Natural Science, and a man of wide attainments. His library contains about 2,200 volumes and embraces a wide field, including zoology, botany, geology, horticulture, travel, exploration, biography and local history. It is particularly rich in general and descriptive zoology of the mollusks, insects and fishes.

Mr. Schuyler S. Wheeler presented to the Institute of Electrical Engineers, New York City, at its meeting on May 21st, the extensive and valuable library of electrical works collected by the late Latimer Clark, of London.

At the monthly meeting of the Royal Meteorological Society on May 15th, Mr. W. Marriott gave an account of the bequest by the late Mr. G. J. Symons to the Society. By his will Mr. Symons bequeathed to the Society his Cross of the Legion of Honour, the Gold Albert medal awarded to him by the Society of Arts, the testimonial album presented to him in 1879 by the Fellows of the Royal Meteorological Society, and the sum of £200, as well as such of his books, pamphlets, maps and photographs of which there was no copy in the Society's library. Mr. Marriott stated that from Mr. Symons's valuable collection he had selected for the society over 5,000 books and pamphlets and about 900 photographs. A large number of the books were old and rare works, 750 bearing dates previous to 1800, while eight were as early as the 15th century. By this bequest the Royal Meteorological Society is said now to possess the most complete meteorological library in existence.

Mr. Carnegie has given £100,000 for branch libraries for the city of Glasgow.

The current issue of *Nature* contains the following further information and comments concerning the resignation of Professor J. W. Gregory from the leadership of the scientific staff of the antarctic expedition:

The great majority of scientific men in the country were confident that Professor Gregory possessed unique qualifications for the post of scientific leader of an expedition in which many branches of science required study and coordination. Under his direction, and with a competent naval head who should have an absolute veto upon all operations which involved risk to ship and crew, great scientific results were assured.

The opposition of the representatives of the Royal Geographical Society, which had obtained most of the funds voluntarily subscribed, and of a few scientific men belonging to the Navy, rendered it impossible that these full powers could be granted; but a compromise acceptable to Professor Gregory was passed

by a large majority (16 to 6) of the Joint Antarctic Committee, including the officers of both societies and almost every expert on their joint lists.

The compromise provided, in the words submitted on February 12th to the joint committee, 'that a landing party, if possible, be placed on shore, under the charge of the director of the civilian scientific staff.' Professor Gregory was informed of this, accepted it, and the next day sailed for Melbourne.

The Royal Geographical Society's council refused to accept the compromise, and deputed three of their number to suggest to the officers of the Royal Society that the matter should be settled by a new committee of six, three to be appointed by each council. The Royal Society consented; the committee, chiefly composed of non-experts, met, and proposed modifications which Professor Gregory has been unable to accept.

We shall await with some interest to see whether the majority of Fellows of the Royal Society, and of other scientific men in this country, will approve the manner in which the Royal Society has acted as the guardian of scientific interests.

A CALL has been issued for the formation of an international botanical association, the first meeting of which will be held at Geneva on August 7th. One object of the association is the establishment of a bibliographic periodical, giving abstracts in English, German and French. An option for the purchase of the *Botanisches Centralblatt* has been secured. The Americans signing the call are Professor W. G. Farlow and Dr. David D. Fairchild, and the secretary is Dr. J. P. Lotsy, Wageningen, Holland.

THE eighty-fourth annual meeting of the Swiss Scientific Society will be held at Zofingen on the 4th, 5th and 6th of August. In conjunction with it, meetings are held of the Geological, Zoological, and Botanical Societies of Switzerland.

THE German Association for the Promotion of the Teaching of Mathematics and the Natural Sciences held its general meeting at Giessen from May 27th to 30th. The program included lectures on the teaching of physics and of geometry and on the use of text-books in the biological sciences.

THE second session of the New York State Entomological Field Station will be held at Ithaca during the summer months. Professor J. G. Needham, of Lake Forest University, will continue in charge of the work. The report of the first session, held at Saranac Inn last summer, is expected to be issued shortly.

THE Peary Arctic Club has chartered for this summer the steamer *Erik*, lately purchased from the Hudson Bay Company by Captain James A. Farquhar, of Halifax. It will sail from Sydney, C. B., about the middle of July, and will return, it is expected, about two months later, with full details of what has occurred during the two years since Mr. Peary has been heard from; also with information of the voyage of the *Windward*, in which Mrs. Peary and Miss Peary sailed from Sydney last year for the North.

IT is reported in the English papers that an American citizen has presented to the Pope a large telescope for the observatory in the Vatican. This observatory, under Father Denza, has carried on active researches since its reorganization in 1888.

A CABLEGRAM to the daily papers from Berlin states that during the past month experiments have been made between Berlin and Hamburg with the system of rapid telegraphy invented by the late Professor H. A. Rowland, of Baltimore, and it is said that the results are most satisfactory—the new system easily doing double the work done by the Baudot apparatus—and that the German Postal Department intends to introduce the Rowland system between Berlin, Hamburg, Cologne, Leipsic, and Frankfort. The system makes possible the transmission of eight messages simultaneously over a single wire, four in each direction, at the rate of forty words a minute.

WE learn from *Nature* that this year's Deutscher Geographentag opened at Breslau on Monday, May 27th. On the morning of May 28th Professor Neumayer proposed to present the report of a committeee upon Antarctic exploration and to speak upon magnetic investigations in polar regions; Dr. E. Philippi on the 'Geological Problems of the German Antarctic Expedition,' and Professor A. Supan on the 'Antarctic Climate.' At the second sitting the subject to be discussed was the organization of geographical instruction, the speakers being Professor H. Wagner, Dr. Auler and Herr H. Fischer. On Wednesday morning, May 29th,

the subjects brought before the meeting related to the scientific study of lands and native races of German colonies. The speakers include Professor F. v. Richthofen, Professor G. Volkens, Dr. E. Kohlschütter, Professor K. Dove and Professor Schenck. The methods of geographical instruction were discussed in the afternoon of the same day by Mr. A. Becker, Professor A. Fischer, Professor A. Kirchhoff, Professor Langenbeck and Professor A. Bludau; demonstrations will also be planned by Professor K. Dove and Dr. M. Ebeling. In the evening an illustrated lecture was announced on glacier markings in Montenegro, by Professor K. Hassert, and one on the volcanoes of central France, by Dr. M. Friederichsen. At the fifth sitting, on May 30th, the papers dealt with various aspects of glaciers and glaciation, and the speakers included Professors Finsterwalder, H. Meyer, S. Günther, A. Penck, W. Goetz and Dr. W. Halbfass. On the afternoon of the same day, reports and papers were received from Professor A. Kirchhoff and C. M. Kan, and Dr. K. Sapper; and the general business of the association was transacted. Excursions have been arranged for a few days at the end of the meeting, and exhibits of geographical interest are on view in two museums in Breslau.

UNIVERSITY AND EDUCATIONAL NEWS.

THE Wisconsin Legislature has appropriated for the University of Wisconsin, at Madison, $210,000, in addition to the regular income previously derived from the State. Of this sum $150,000 is for a new building for the College of Agriculture, which is to house the administration offices of this department and the experiment station as well as the departments of bacteriology and chemistry. This College also receives $10,000 annual increase to its present income. The College of Engineering receives $30,000 for equipment of its new building which was provided by the last Legislature; also $7,500 annual increase in income. The newly organized School of Commerce secures $3,500 annual increase in its appropriations.

MR. EDWARD TUCK has given Dartmouth College $100,000 for a building for the Amos Tuck School of Administration and Finance. The College has also received a bequest of $10,000 from Mrs. Susan A. Brown as a library fund for the Department of Philosophy.

THE trustees of the John Carter Brown Library, acting under the provisions of the will of the late Mr. John Nicholas Brown, have decided to present the library with its $650,000 endowment to Brown University. This is the finest collection of Americana in existence. In addition to the books, whose value it is difficult to estimate, there will come to the university $150,000 for a library building and $500,000 of permanent endowment.

MR. ANDREW CARNEGIE has, as our readers doubtless know, offered to give £2,000,000 to the four Scottish Universities, Edinburgh, Glasgow, Aberdeen and St. Andrews, for the free education of Scottish students. He estimates that this income will pay the fees of all the students in the universities, including, we understand, the professional schools.

THE Council of Columbia University has resolved that all candidates for degrees at commencement shall be presented in English and that all degrees shall be conferred in English. Hitherto Latin has been used in part.

PROFESSOR R. W. WOOD, of the University of Wisconsin, has been appointed professor of physics in the Johns Hopkins University.

PROFESSOR H. B. LATHROP, who holds the chair of rhetoric at Stanford University, has resigned and has accepted the position of assistant professor of English in the University of Wisconsin.

ALBERT PRESCOTT MATHEWS, PH.D. (Columbia), has been elected assistant professor of physiological chemistry in the University of Chicago, and will be head of the department.

DR. O. M. STEWART, instructor in physics in Cornell University, has been appointed assistant professor of physics in the University of Missouri.

DR. E. SCHELLWEIN has been promoted to an assistant professorship of geology and paleontology at the University at Königsberg.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, JUNE 7, 1901.

FRANÇOIS MARIE RAOULT.

THE death of Raoult, on April 1, 1901, removes from France one of her most brilliant investigators. Raoult was born at Fournes (Nord) on May 10, 1830, and was, therefore, nearly seventy-one years old when he died. After finishing his academic training in Paris, he began his career as a teacher in the Lycée at Reims at the age of twenty-three. In 1870 he was called to the chair of chemistry at Grenoble. In 1889 he was elected dean of the Faculty of Sciences in Grenoble—a position which he held until his death.

The earlier work of Raoult was devoted to problems of a purely physical nature. His thesis, presented for the degree of Doctor of Science was on 'The Electromotive Force of Voltaic Cells,' and much of his earlier work had to do with the phenomena connected with electrolysis.

His most important work, however, and that with which his name will always be connected, was done after 1870, while at Grenoble. When Raoult took up the study of the lowering of the freezing-point and of the vapor-tension of solvents by dissolved substances, our knowledge of these phenomena was hardly more than qualitative. A few regularities had been pointed out by Blagden, Coppet, Wüllner, Emden, Rüdorff and others, but scarcely any generalization worthy of the name had been reached.

The reason why the laws which obtain in these fields had not been discovered is to be found chiefly in the fact that aqueous solutions had been used, and we know to-day that water dissociates electrolytes, and in varying amounts depending upon the dilution of the solution. Thus, of all the solvents which could have been used in studying these phenomena, no one was so poorly adapted to the discovery of any relations which might exist as water.

When Raoult took up the study of the lowering of the freezing-point of water by dissolved substances, he did not limit himself to aqueous solutions, but employed solutions in acetic acid, benzene, nitro-benzene, etc. From his work with non-aqueous solutions he discovered his well-known law: "A molecule of any substance dissolved in one hundred molecules of a liquid lowers the freezing-point of the latter a nearly constant amount." The experimental data upon which this law is based were published in 1884.*

A little later (1886) Raoult took up the study of the lowering of the vapor-tension of solvents by dissolved substances. Here also he worked with non-aqueous solutions, and showed that the lowering of the vapor-tension is proportional to the ratio between the number of molecules of the dissolved substance and the total number of molecules present.

The work of Raoult, then, brought out this important point, that the lowering of the freezing-point of a solvent, as well as the lowering of its vapor-tension, depends only upon the ratio between the number of parts of the dissolved substance and the number of parts of the solvent which are present.

This work of Raoult, however, led to a still more important discovery. He found that electrolytes, *i. e.*, those substances which in solution conduct the current, give greater lowering of the freezing-point of water than non-electrolytes. An example will make this clear. Hydrochloric acid, sodium hydroxide and sodium chloride in water lower its freezing-point nearly twice as much as methyl alcohol of the same concentration. We recognize in the acid, base and salt types of electrolytes, and in methyl alcohol a typical non-electrolyte. Raoult was not able to point out the meaning of this important discovery. This was left for another.

The work of Pfeffer on the osmotic pressure of solutions led, in the hands of van't Hoff, to the discovery of the relations between the osmotic pressure of solutions and the gas-pressure of gases. But these relations hold only for the osmotic pressures of non-electrolytes. The electrolytes all exert an osmotic pressure which is greater than that shown by the non-electrolytes. van't Hoff was not able to explain the abnormally large osmotic pressures exerted by the electrolytes.

The Swedish physicist, Arrhenius, took up this question, and, as we know, furnished a satisfactory answer to it. He asked, Why is it that electrolytes give abnormally large osmotic pressures, abnormally large depressions of the freezing-point and vapor-tension of solvents? The work of Raoult had shown that lowering of freezing-point and of vapor-tension depends only upon the number of parts present in a given volume of the solution. Therefore, when these phenomena manifest themselves to an abnormally large degree it means that we have more parts present in the solution than we suppose. This gave to Arrhenius the key to the solution of the problem, and the theory of electrolytic dissociation was the result.

This work of Raoult, together with that of Pfeffer on osmotic pressure, forms the foundation of the new physical chemistry.

An account of the work of Raoult should

* *Ann. Chim. phys.* [6] **2**, 66. Harper's Science Series, IV.

be supplemented by a brief reference, at least, to his more important characteristics. He was not a man who desired fame, but devoted his whole life to one ideal—the discovery of truth. Although connected with a comparatively small institution, he never lost his enthusiasm for his work, and one of his very last investigations, on the lowering of the freezing-point of water produced by non-electrolytes, probably contains the most accurate measurements of these values which have ever been made.

Raoult as a man seems to have combined most of those qualities which are so much admired. We have abundant evidence of his kind-heartedness and genial disposition. A letter from his pen was always an inspiration to more strenuous effort in research, and invariably left the impression that the highest aim of man should ever be to increase the sum of human knowledge.

In Raoult not only France has lost her most prominent physical chemist, but the world has lost one of the leading men of science.

HARRY C. JONES.

CHARLES HERMITE.

THE fourteenth of January, 1901, should be marked with a black stone in the annals of mathematics. Then the eminent geometer, the incomparable man, the great Hermite, one of the glories most pure of France, was lost to science, and implacable death threw into mourning his family, his friends and his admirers.

As mathematician of the first rank he leaves to the glory of his country and of all humanity a superb scientific monument erected in sixty years, completely dedicated to 'his dear *analyse*' (to use one of his phrases) and to preparing, by the infusion of his genius placed at the service of teaching, that galaxy of illustrious mathematicians who now so much adorn our sister nation. Like Sturm, he united in an extraordinary degree the qualities of a professor who wins the love of his disciples to those of one who inculcates the love of science for science.

Endowed, like his compatriots Pascal and Clairaut, with singular precocity, we see him, yet a scholar of the lyceum Louis le Grand, win the prize for mathematics with a noteworthy thesis, and shortly after, as student of the Polytechnic School, attract the attention of Jacobi with his first works and place himself as of right in the first rank among the analysts of Europe.

It is not our object to make a minute analysis of the works of the great geometer, to which would be necessary time and competence that we lack. Our aim is much more modest; we seek to render what is heartfelt homage to the man we have so deeply venerated and from whom we have received infinite proofs of benevolence during the fifteen or sixteen years that we have had the honor to possess his friendship, in so many ways precious.

It is not possible, speaking of Charles Hermite, to fail to say how in the higher analysis, in algebra and in the theory of numbers, one encounters everywhere the footprints of his giant tread. How could we leave unmentioned his memoir on the exponential function, where in demonstrating the transcendence of the number e he opens the way which eleven years after conducted Lindemann to the demonstration of the analogous property of π, solving in negative form the celebrated problem which for two thousand years had in vain fatigued geometers?

Nor can we pass in silence the enormous contribution which Hermite brought to the *Theory of Forms:* his law of reciprocity, his admirable researches on associate covariants, his work on quintic forms, his memoir on the equation of the fifth degree and his celebrated theorem having Sturm's as corollary.

The works of Charles Hermite in the theory of functions are a new revelation of his genius. His profound investigations on Abelian functions, their division and their transformation, as also those relative to elliptic functions, form a monument of glory erected to French science, disclosing the sagacity of the grand analyst in the facility with which are deduced from the most lofty analytic investigations, corollaries which unveil difficult properties of the theory of numbers.

Neither can we neglect to mention the work, 'Sur quelques applications des fonctions elliptiques' (1885), of which only the first part was published: in this are found the beautiful applications of these functions which conduct him to the general integral of the equation of Lamé on the equilibrium of temperature of a homogeneous ellipsoid, which leads the author, in two particular cases, to the study of the rotation of a solid body around a fixed point (when there do not exist accelerating forces) treated by Jacobi, and to the consideration of the conic pendulum.

So far as we know, Hermite leaves two didactic works: his 'Cours de la faculté des sciences de Paris' (1891), and his 'Note sur la théorie des fonctions elliptiques' (168 pages), which serves as appendix to the 'Cours de calcul differentiel et integral,' of J. A. Serret (4th ed., 1894).

We have from him also two brief but interesting notes on the invariants of binary forms of the 5th and 6th order in the French translation of Salmon's 'Higher Algebra.'

The French geometer had the good fortune not granted all great men to see recognized in his lifetime by the scientific world his extraordinary merit. The 24th of December, 1892, his sixtieth birthday, the friends, the disciples, the admirers of the great geometer assembled at the Sorbonne to present him the gold medal struck in his honor by international subscription. The illustrious artist Chaplain cut upon it the bust of the one commemorated, and translated on to metal with admirable fidelity his venerable face, affable and frank, illuminated by the scintilla of genius.

The Minister of Public Instruction, M. Ch. Dupuy, presented to Hermite in the name of the President of the Republic the insignia of Grand Officer of the Legion of Honor, and the messages were read of those who from various parts of the world associated themselves with the splendid ceremony.

High testimony of admiration and sympathy was offered the great geometer more recently upon the occasion of the meeting at Paris, last August, of the International Congress of Mathematicians.

The Congress sent him a telegram of admiration and sympathy (he was at Saint-Jean-de Luz). This act caused vast satisfaction and profound emotion to the scientist, as he wrote me in one of his last letters.

Hermite retained to the last day of his life his privileged intelligence; but his body suffered. In a long letter of his, a few days before his death, he complained of his attacks of asthma and of the lack of appetite and of sleep: he seemed to foresee the nearness of his end, so that sending me one of his works, he said that this would be without doubt *the last!* and that he had in great part accomplished it at Saint-Jean-de Luz, where by benefit of the mild climate had reawakened his mathematical activity. This last work is a letter to Professor Pincherle published in Tomo V. of the *Annali di Matematica.*

He told us also that he had sent a brief article to the new journal, *Le Matematiche*, of Professor Alasia.

We will end by expressing a wish. We wish that those who have the authority would take the initiative toward an international subscription for a work containing an extended biography of the ever-memo-

rable geometer, and a minute analysis of his works; perhaps might be added some brief articles by very illustrious living mathematicians; something, in fine, which would be as a funeral crown offered to the memory of the great dead.

[Written by Juan J. Durán-Loriga for *Le Matematiche*, and translated by the English editor G. B. Halsted.]

THE EXTRA-NUPTIAL NECTARIES IN THE COMMON BRAKE, PTERIDIUM AQUILINUM.

THE common brake, *Pteridium aquilinum* Kuhn (*Pteris aquilina* L.) has for a number of years been used in educational institutions in this country as a laboratory type, more especially in connection with introductory courses in general biology in which both animal and plant types are used. That the presence of nectar-secreting organs in this form, therefore, should have been so generally overlooked as the writer has been led to believe, the more especially as they were made known to the botanical world as early as 1877,* is a matter of some surprise.

It is our purpose by means of the present paper to review the facts already published, and to present them, together with the writer's own observations, in order to draw to the attention of teachers of biology the fact of the presence, in a non-flowering plant, of an organ such as is thought of usually in connection with the phanerogams alone. Interest attaches to this structure, also, from the fact that a definite organ of secretion may be observed by students in a much-used laboratory type, thereby enhancing its value as such.

The extra-nuptial nectaries in *Pteridium aquilinum* were discovered by Francis Darwin (*l. c.*), and their microscopic appearance was briefly described by him in 1877. The possible biological meaning of these organs was also discussed.

* Darwin, Francis. *Jour. Linn. Soc.* **15**: 407. 1877.

Two years later, Bonnier* pointed out the presence of similar structures in certain genera of ferns, namely, in *Cyathea*, in *Hemitelia* and in *Angiopteris*, and briefly described some points in their anatomy. In addition, this author examined the nectar of the plant here under discussion.

In 1891, in view of the scanty description till then extant, W. Figdor† published a fuller account of the nectaries in *Pteridium*. This description includes the external appearance and the histology of the gland, and is accompanied by two illustrations. Later in the same year Figdor's paper was reprinted, accompanied by some notes and one illustration‡ additional, by H. Potonié.§

EXTERNAL APPEARANCE.

The nectaries in *Pteridium aquilinum* occur on the fronds at the bases of the pinnæ and pinnulæ on the morphological lower side of the leaf. The largest and most conspicuous are the lowermost, that is, those at the bases of the first pair of pinnæ. On one developing frond, therefore, one may observe a complete developmental series. When examined macroscopically the glands appear as approximately oval areas just below and extending somewhat into the angles formed by the mid-veins of the first and second, and second and third, orders. The external surfaces of the glands are smooth, because of the absence of the chaffy scales found elsewhere on the young frond.

* Bonnier, G. 'Les nectaires.' Ann. Sci. Nat. Bot. VI. **8**: 5-212. 1878.

† Figdor, W. 'Ueber die extranuptialen Nectarien von *Pteridium aquilinum*.' Oesterr. botan. Zeitschr. No. 9. 1891.

‡ Reproduced in Engler and Prantl's 'Natürlichen Pflanzenfamilien,' **1**[4]: 67.

§ Potonié, H. 'Die 'extranuptialen' Nectarien beim Adlerfarn.' Natur-Wiss. Wochenschr. **6**: 401. 4 O. 1891.

Their color, according to Figdor, is brown-red in the central part of the nectarial surface, developing into red on the edges. Darwin's statement is that they are 'smooth green.' In our east North American plants, the color in the young state is much as described by Figdor. Later the red color is lost, and the organs are then deep green. Darwin's and Figdor's statements may, therefore, be harmonized as they appear to apply to different stages of growth, if indeed the European plants do not differ among themselves and from the American. Figdor further notes that the membranes of the nectaries early become brown and that, later, they thicken considerably. The use of the red color is quite problematical.

The secretion of nectar is very abundant during the unfolding of the frond. So abundant is it, in fact, that large beads of the limpid fluid may be seen from a distance, resting on the nectaries or running down the petiole. With a hand lens, one may easily note the accumulation of nectar after the surface has been wiped off. Darwin found that a drop of the liquid was formed in six minutes. Handling and tasting the secretion shows it to be sirupy and very sweet. According to Bonnier (*l. c.*) the sugars saccharose and glucose are present. Here, as in analogous organs in other plants, the exudation is quite independent of bleeding pressure. Leaves which have been broken off continue to produce nectar for some days, provided, of course, that they be kept in fair condition. As the frond ages, the activity of the glands is lowered, until they finally cease to secrete and become functionless as nectaries.

ANATOMY.

The epidermis consists of polygonal cells, with a depth that is greater by about one-third than that of the rest of the epidermal cells of the petiole; in transverse section they are nearly square (Fig. 5). These cells have red coloring matter in their sap, although the color is not confined merely to the glandular areas, but is usually extended from them in bands of various breadths up and down the petiole. The loss of this color as the age of the leaf increases has been noted above.

Scattered here and there on the surface are a number—a dozen or more—of stomata. These are irregular in position, in surface view very much rounded (Fig. 1a), resembling in this respect very closely the water pores of the garden nasturtium (*Tropaeolum* sp.).

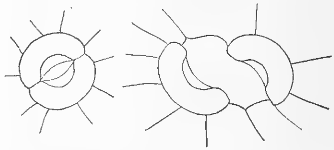

FIG. 1a. Stoma from nectary.

FIG. 1b. Stoma in which the guard cells have been spread apart by growth of the surrounding tissues.

They do not, however, lack so entirely the characters found in air stomata, as is shown in the figure. The delicate hinge mechanism is not present, and the thickening of the walls is even all around, in which the stomata agree in essential detail with water stomata, such as are found in *Secale cereale, Conocephalus ovatus* and other plants.

In some cases the stretching of the epidermis incident to growth causes a displacement of the guard-cells (Fig. 1b), and a consequent enlargement of the pore. The guard-cells are raised above the general surface (Fig. 2), in which particular the writer's observations fail to coincide with those of Figdor, whose illustration in other regards also does not show the guard-cells to possess any characters usually found in such. Figdor states that a 'test with a sugar solution indicated that some of the

stomata carry on the usual function while others serve for the exudation of nectar.'

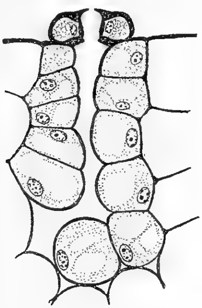

FIG. 2. Transverse section through a stoma and adjacent tissue of the nectary.

It is, however, not clear how the test was applied, and we believe that in view of the facts the question of the function of the stomata may be decided upon other grounds. A very few of these which occur on the edge of the nectarial surface have the appearance of air stomata, but by all odds the big majority have the characters above described, from which it appears that the guard-cells are in such cases quite functionless in opening or closing the entrance. Furthermore, the nectar when it is being secreted is so abundant that it must needs hinder completely the gas interchange at that time. That such interchange takes place later is almost certainly the case, as is indicated by the condition of the chlorophyll-bearing cells of the gland. Nor does the immobility of the guard-cells call for remark, inasmuch as the amount of tissue involved in transpiration coincident with respiration is relatively so very small as to have no effect upon the turgor of the whole leaf. Stomata are absent from the rest of the petiolar surface, excepting that, as Potonié * has pointed out, they are present along two bands on either side of the morphological upper flattened side of the leaf-stalk, beneath which the hypodermal stereome is absent, though elsewhere present except in the nectaries. The relation of these bands to the glands should here be pointed out. As just stated, the rachis possesses two such bands, which pass *without dividing*, each along the lower margin of one of the first pair of pinnae. The band lying along the upper margin of a pinna and that along the side of the rachis nearer the same and above its insertion arise *at the same point.* At this point lies the nectary. These relations, which are exhibited in Fig. 3, *a* and *b*, are repeated at each fork in the frond.

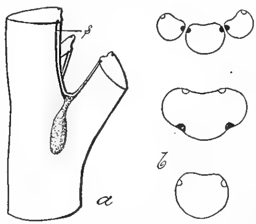

FIG. 3. *a*, lateral view of rachis showing the nectary and the stomatal bands, *s*; *b*, diagrams showing the distribution of the bands.

Through these true pneumathodes, by reason of the anatomical relations just indicated, the gas interchange may easily take place between the glandular tissue and the air. On old dead fronds the nectarial stomata are so large as to be seen with the naked eye, from which fact the presence and extent of the gland beneath may be determined.

Beneath the epidermis lies the glandular tissue extending to a depth of 1 mm. or a fraction more. In a transverse section through fresh material, the extent of the same may be recognized by the deeper green color contrasting with the lighter color of the surrounding tissues. The cells are rounded in form, as described for

* Potonié H. Jahrb. des Königl. bot. Gartens zu Berlin, **1**: 310–317. 1881.

Hemitelia by Bonnier (*l. c.*), and contain relatively much more protoplasm than the contiguous cells, large nuclei and chloroplasts. The cytoplasm is vacuolated and the cell walls are thin. The cells stand in contrast with the ground parenchyma on account of their smaller size, their diameters being between the ratio of 1 to 3 and 1 to 4. The cells near the epidermis are larger than those lying deeper in the gland. In making the foregoing statement, we differ from Figdor, who says "The single elements of the gland are about the size of the cells of the fundamental parenchyma." Frequent small intercellular spaces occur. These connect with each other and finally with the substomatic spaces which are of considerable size (Fig. 2). Through these, therefore, the secretion may find its way to the surface of the gland. Bonnier, in the paper above cited, makes no mention of the substomatic spaces in the special treatment of the ferns. Further on, however (p. 151), he makes a general statement to the effect that he had established the fact that, in the cases of nectaries with stomata, these are either without a substomatic space or have only very small ones. His figure representing the nectary of *Hemitelia obtusa* (on his Pl. 1, Fig. 9) certainly bears out his general statement. We cannot, however, regard this figure as satisfactory. No attempt was made to delineate the stomata, except in very schematic fashion, on account of the small size of the drawing, for which reason also the possibility of representing substomatic and intercellular spaces was very much lessened. The presence of a large substomatic space, however, may not be regarded as of any importance in the economy of such an organ as a nectary, in which the movement of the fluid is the important and characteristic feature.

Passing on to consider the relation of the nectary to the vascular tissue, we notice in the first place the distribution of bundles in the immediate vicinity of the former. Fig. 4 shows, in diagrammatic form, this relation, from which there appears to be little variation to be noted beyond. A broad

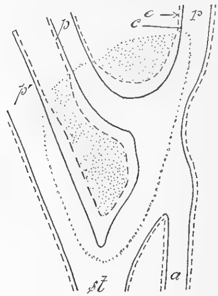

FIG. 4. Diagram showing the relations of the vascular tissue and gland. The dotted outline shows the extent of the latter. *c*, limit of the cribral part of the bundle; *e*, endodermis. The pericycle is included between these.

stele* (*st*) divides at the lower angle of the nectary, one branch (*p′*) running along one side of the gland and thence into the pinna, the other and larger passing along the other border of the gland, broadening as it goes into a vascular plate which consists of a dense complex of short, irregular wood elements, well-developed cribral cells and a several-layered pericycle, to be described below.

From this plate of vascular tissue, which lies beneath and somewhat obliquely across the nectary, pass forward two branches, *p* and *r*, which go into the pinna and rachis, respectively. Sometimes four branches arise by the splitting of these two, but the general character of the arrangement is quite constant. Sometimes a small stele runs into the complex, as shown at *a*, Fig. 4.

* The term stele is used here, in the ferns, without reference to the question of morphological propriety. See Jeffrey, E. C., 'The morphology of the central cylinder in the angiosperms,' *Trans. Can. Inst.*, Vol. 6.

In no case examined, however, does a bundle end in a gland, as held by Figdor (*l. c.*). The relations of the glandular and vascular tissues are none the less intimate and striking, as we shall see in coming to the second point.

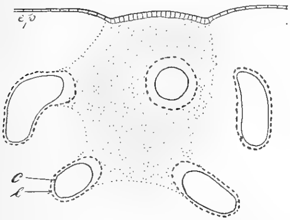

FIG. 5. Diagram of a transverse section through a nectary. *ep*, epidermis; *c* and *e*, as in Fig. 4.

In examining a transverse section we see the glandular tissue extends towards and comes partially to surround the vascular bundles adjacent (Fig. 5), and, further, that the pericycle of these bundles, in the regions contingent upon the gland, consists of three to four layers of enlarged cells, and not, as is to be found elsewhere, of a single layer of cells (Fig. 6, *a* and *b*). These enlarged pericycle cells are abundantly supplied with cytoplasm of fine, tenuous structure with large and often irregularly shaped nuclei. The cytoplasm is little vacuolated.

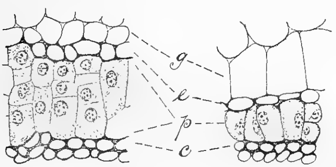

FIG. 6. *a*, transverse section through a portion of the pericycle in contact with the glandular tissue. *b*, a similar portion in a bundle adjoining the ground tissue. *c*, cribral cells; *p*, pericycle; *e*, endodermis; *g*, ground parenchyma.

The pericycle cells found elsewhere in the petiole, where the glands are active, are supplied with a scant amount of cytoplasm. The endodermis,* which is usually regular and well marked, is, in the vicinity of the nectary, quite irregular and often difficult to recognize, and its cells have very much the character of the adjoining gland cells in shape and content. We may thus regard these cells, namely, those of the endodermis and pericycle, where the bundles and nectary touch, as a part of the gland. Whether we may assign a different function or the same to these cells may not be answered. Bonnier (*l. c.*) has indicated that, besides the two sugars above named, an invertin is to be found in the gland. The suggestion occurs to us that this substance originates in the pericycle. Nevertheless, the greater development of the pericycle as already indicated can perhaps be entirely accounted for by the activity of its cells in passing the soluble carbohydrates from the moving sap into the gland.

After the activity of the gland ceases, the thickening of the walls of the endodermis commences, in all the bundles lying in the petiole near the fork formed by the pinna, and the process extends to the surrounding parenchyma. In this way the strength of the fork is very materially heightened. We notice also, with Figdor, a thickening of the walls of the gland cells, a process which takes place in all the chlorophyll-bearing cells beneath the stomatal bands.

In offering a teleological explanation of the organs above described, F. Müller pointed out that in Brazil the fern is visited by an ant (*Cremogaster* sp.) of which a leaf-cutting species, an *Oecodoma*, stands in dread. To this Francis Darwin † answers that the plant has few natural enemies—meaning, presumably, in England, though this is equally true, so far as observation goes, in North America. Francis Darwin further suggests, in the view of the possible weakness of the above explanation, that the

* Derived from the phloeoterma of Strasburger.

† *Nature*, **16**: 100.

gland is either an organ which was formerly of use and is now passing away, or that it is connected 'with some unknown process of nutrition.' That its activity 'is decidedly connected with the growth of young fronds' stands in favor of the latter view. A supplementary suggestion has already been made by the writer to the effect that the solution of actively secreted sugar may act as a carrier for some other substance in the nature of an excretion.*

The writer has observed on the surface of the gland in some cases a felt of dark-colored fungal hyphae. The occurrence of these, when the leaf-blade has not yet unfolded, carries with it the suggestion that the nectarial surface is a constant infection-point, the sugary fluid acting as a nutrient medium and the entrance of the hyphae being made easy by the large stomata.

ORIGIN OF THE NECTARY.

Certain facts which have been pointed out give us grounds for offering a view of the origin of the nectaries, to the effect that they have arisen as portions of the respiratory areas of the petiole and its branches, which have become secondarily specialized as nectar-secreting glands.

In support of this view, we recall the relation of the nectaries to the stomatal bands (pneumathodes), with which they have a practically identical structure, with, however, a more intimate connection with the vascular system. We regard the wide distribution of these band-shaped pneumathode regions in the ferns as indicating a phylogenetically greater age than that of the nectaries as such. If this be true, Francis Darwin's suggestion, quoted above, that the nectary is an organ once useful but now on the wane, must probably be thrown out of court, though not necessarily. Further, the stomata, while clearly functionless as pneumathodes during the period of the gland's activity, and deprived of the delicate mechanisms for closure both by their own development and the manner of growth of the surrounding epidermis, are nevertheless to be regarded as respiratory mechanisms, serving the function of setting free the nectar. The analogous conditions in *Tropaeolum* and other plants may be cited as a parallel case save in the nature of the exudate. The presence of the substomatic spaces, usually broader beneath the stoma than represented in Fig. 3, together with the intercellular spaces both suggest the same thing.

It is to be questioned if the presence of chlorophyll in the gland has any necessary relation to the activity of the organ as a gland, upon which point further study of the cytological phenomena may throw light.

Haberlandt* has drawn the provisional conclusion with regard to nectaries in general, that they have been derived phylogenetically from hydathodes. In summarizing the present paper we submit the case described herewith as one in which the nectaries have been derived both ontogenetically and phylogenetically from pneumathodes.

THE BRITISH NATIONAL ANTARCTIC EXPEDITION.†

THE resignation of the man who is, before all others, fitted to be the Scientific Leader of the National Antarctic Expedition will lead the fellows of the Society to expect some statement of the causes which have produced a result so disastrous to the interests of science. The following statement gives an account of the efforts which

† A letter addressed by Professor Edward B. Poulton, of Oxford University, to the fellows of the Royal Society.

have been made to prevent the injury which has occurred.

In the autumn of 1899, Captain Tizard, F.R.S., and I were appointed as the representatives of the Council of the Royal Society on an Antarctic Executive Committee of four, Sir Clements Markham (Chairman) and Sir R. Vesey Hamilton being the representatives of the Royal Geographical Society's Council. Our functions were defined under various heads in a printed form previously agreed upon. No. 2 instructed us to submit a program of the Expedition for approval to the Joint Antarctic Committee (consisting of sixteen representatives of each Council), "such a programme to include (*a*) A general plan of the operations of the Expedition, including instructions to the Commander, so far as this can be laid down beforehand. (*b*) The composition of the executive and scientific staff to be employed, the duties, preparation and accommodation for, and pay of, the several members." No. 4 instructed us "to make the appointments of the several members of the executive and scientific staff, subject to the final approval of the Joint Committee." The word 'civilian' was nowhere employed. The four members of the Executive Committee were placed on the Joint Committee and all Sub-Committees.

Before the first meeting of the Executive Committee, Captain Tizard and I were seen by Professor Rücker, who informed us that one of the first points which the Council of the Royal Society desired us to raise was the relation in power and status between the Commander and the Scientific Leader. In the German Expedition, which was to start about the same time, the Scientific Director had absolute power, and we were asked to consider the possibility of such an arrangement in the English Expedition.

At one of our first meetings, I think the very first, I raised this question and supported the German arrangement. The other three members, who were all naval experts, convinced me that English law required the Captain to be supreme in all questions relating to the safety of his ship and crew. Since that time I have never disputed this point, but always maintained that the scientific chief should be head of the scientific work of all kinds, including the geographical, and that the Captain should be instructed to carry out his wishes, so far as they were consistent with the safety of ship and crew.

We then considered the appointment of Scientific Leader and decided to nominate Professor J. W. Gregory, then of the British Museum of Natural History. In suggesting his name to my colleagues, I was influenced by his proved success in organization and in the management of men in a most difficult expedition (British East Africa in 1893), by the wide grasp of science which enabled him to bring back valuable observations and collections in so many departments. His ice experience in Spitzbergen and Alpine regions was also of the highest importance, together with the fact that his chief subject was geology, a science which pursued in the Antarctic Continent would almost certainly yield results of especial significance. In addition to all these qualifications, Professor Gregory's wide and varied knowledge of the earth rendered his opinion as to the lines of work which would be most likely to lead to marked success extremely valuable in such an expedition. No one was more competent to state the probable structure of the Antarctic Continent and its relation to that of the earth. This opinion of Professor Gregory's qualifications for the position of scientific leader of an Antarctic expedition is, I know, widely held among British scientific men. In their wide combination, and united as they are to tried capacity as a leader, they are unique, and

an expedition with Professor Gregory for its scientific chief, with as free a hand as English law would permit, was bound to yield great results.

The Committee deputed me to ask Professor Gregory if he would consent to be nominated. In doing so I carefully explained that he could not have the full powers of the German scientific leader. He consented to consider the offer favorably, but wished for a more definite statement of his position and powers, and for a program of the Expedition. Shortly after this he was appointed professor of geology at Melbourne, and left England. On the voyage he wrote a long letter to the Executive Committee (dated January 19, 1900), which he posted to me at Port Said. In it he said, "I have heard so many rumours as to what is wanted, that I cannot be sure whether I correctly understand the views and wishes of the Executive Committee: I therefore write mainly for the sake of correction, so that I may avoid any misstatements in communicating with the Council of Melbourne University, when the proposal from the Committee reaches me." The plan drafted by Professor Gregory in this letter included the provision of a landing party with house, observing huts, dog-stable, etc., and he argued that its organization should be placed 'in the hands of the scientific staff,' but that, under any circumstances, the Scientific Leader should have the opportunity of controlling a small independent party on land. This letter was read by all the members of the Executive Committee, and, on June 15th, at the close of the meeting, the Secretary despatched a cable to Professor Gregory containing the information "Your letter of January 19 has been received and approved." As soon as Professor Gregory received this he sent a decoded copy to Sir Clements Markham, who did not correct it. Indeed, at this period Sir Clements Markham frequently expressed opinions which implied that he contemplated the establishment of a landing party independent of the ship. Professor Gregory applied for and received from the Council of Melbourne University permission to take the appointment on the lines of his letter of January 19th.

Professor Gregory's name was very warmly received by the Joint Committee and he was appointed Scientific Head on February 14, 1900; the words "Formally appointed, wire when fully able to decide," being cabled to him a few days later by Sir Clements Markham.

Lieutenant Robert F. Scott, Torpedo Lieutenant of H. M. S. *Majestic*, was appointed Commander of the Expedition by the Joint Committee, on May 25, 1900.

In June, 1900, my attention was called to a statement in the *Press* describing Professor Gregory as 'Head of the Civilian Scientific Staff.' Feeling confident that the word 'civilian' was not employed in the resolution accepted by the Joint Committee I wrote to Sir Clements Markham on the subject. In his absence the Secretary replied, "The words 'Head of the Civilian Scientific Staff' are the exact words of the resolution passed by the Joint Committee appointing Professor Gregory, and I know Sir Clements himself was very anxious to have the word 'civilian' in, so that no difficulty might arise between Professor Gregory and the Commander of the Expedition, since the civilians would not be the only scientific men on board." The word 'civilian' does certainly occur in the minutes of the meeting. On the other hand, Sir Clements Markham was not present on that occasion (February 14, 1900); the word 'civilian' did not occur in the instructions issued to the Executive Committee, and was not used in my letter to Sir Clements (February 15th) describing the result of the meeting and asking him to cable.

The words I used, 'leader of Scientific Staff,' were not commented upon in his reply (February 16th), stating that the cable should be sent. The word 'civilian' was not used by Dr. W. E. Blanford, writing to convey the unanimous recommendation of the Geological Sub-Committee that Professor Gregory should be 'chief of the Scientific Staff of the Expedition.' Professor Herdman, who seconded the resolution on February 14th, and I, who proposed it, both remember the words 'Scientific Leader of the Expedition.' I have not been able to recover a copy of the notice convening the meeting, in which the agenda were put down. It would, however, have been unreasonable for the Joint Committee to have accepted the word 'civilian' when it had no information before it which justified the expectation that naval officers would be lent by the Admiralty.

At the meeting of the British Association at Bradford, I explained the situation to Professor Rücker, who agreed with me that it was full of danger, on account of the reasons alleged for the use of the word 'civilian,' viz., in order to discriminate between the science under Professor Gregory and that under the Commander. He agreed with me that the coordination of all the science of the expedition ought to be in the hands of the scientific chief who had been selected, because his reputation was a guarantee that all interests would be properly looked after. Sir Michael Foster, to whom I mentioned the matter at a later date, quite agreed with this opinion, but was unwilling to contest the use of the term 'civilian.' Furthermore, when I raised the question at a meeting of the representatives of the Royal Society on the Joint Committee, it appeared that the term was actually preferred by certain influential naval authorities who were present, so that it was impossible to resist it without dividing those who desired to give Professor Gregory such a measure of freedom of action as he was prepared to accept.

At the meeting (November 20, 1900) of the Joint Committee, following the conversations with Professor Rücker and Sir Michael Foster, a report from the Executive Committee and submission and estimate from Captain Scott were read and received, with certain modifications. I indicated to the Secretaries of the Royal Society, who were sitting opposite to me, that this was a favorable opportunity to raise the question of the powers of the Scientific Director over the whole of the science of the Expedition. They were, however, unwilling to do so, hoping, I believe, that all difficulties would be smoothed away by personal negotiations between Captain Scott and Professor Gregory, who was expected home in a fortnight.

For nearly two months these negotiations proceeded between Professor Gregory on the one side and Captain Scott and Sir Clements Markham on the other, and between Sir Clements Markham and me.

The principles held were irreconcilable, and it only remained to appeal to the Joint Committee for a decision.

On January 9, 1901, Professor Gregory wrote to Professor Rücker, explaining the failure of the negotiations, and on January 28th he addressed a letter to the Royal Society's representatives on the Joint Committee, from which I select the following paragraphs:

I landed at Liverpool on December 5, and went straight to Dundee to meet Captain Scott, and showed him a copy of my letter of January 19 [1900]. As he returned it to me next day without comment, I believed that he understood and accepted the general conditions therein stated. On January 7, in order to settle the exact terms of our mutual relations, I submitted to Captain Scott a draft of the instructions I expected to receive from the Joint Committee, and which I had previously shown to Professor Poulton. To my surprise Sir Clements Markham and Captain Scott expressed disapproval of these instructions, practically on the ground that there could be only

one leader of the Expedition, and that that leader must be Captain Scott.

My colleagues and myself were characterized as civilian scientific experts, accompanying the expedition to undertake investigations in those branches of science with which the ship's officers were unfamiliar, and it was proposed that, to maintain Captain Scott's complete control, all the scientific men should be required to sign articles.

According to this theory, the position of the scientific staff is accessory and subordinate. The contentions of Sir Clements Markham and Captain Scott would completely alter the position which I was invited to take and which alone I am prepared to accept. Were I to accompany the expedition on those terms there would be no guarantee to prevent the scientific work from being subordinated to naval adventure, an object admirable in itself, but not the one for which I understood this expedition to be organized.

The Executive Committee met on January 30th and drafted instructions on lines approved by Sir Clements Markham. They were opposed by my colleague Captain Tizard, but in my absence through illness were passed by two votes to one.

A few days later the draft instructions were considered by the Royal Society's representatives, who appointed Sir Joseph Hooker, Sir William Wharton and Sir Archibald Geikie to suggest amendments. They carefully considered the draft and suggested several alterations, the most important of these being the instructions to the commander, (1) not to winter in the ice, (2) to establish between two named points on the coast a landing party with three year's stores, under the control of Professor Gregory.

The Royal Society's representatives again met and unanimously approved these amendments, which were submitted together with the draft instructions to the meeting of the Joint Committee on February 8th. The representatives of the Royal Geographical Society objected that they had not had the same opportunity of considering the instructions at a separate meeting, and that the amendments were sprung upon them. The meeting was accordingly adjourned until February 12th, the very day before Professor Gregory sailed. During the prolonged discussion which took place, the authorities on magnetism were unanimous in affirming that a station on land was essential in order to obtain the full value of the observations made on the ship.

Sir Clements Markham threatened that the Council of the R. G. S. would not accept the amended instructions, whereupon Sir Michael Foster drew attention to the letter which Sir Clements had written at the time when the Joint Committee was proposed.

The amendments were finally approved by 16 votes to 6, and Sir Archibald Geikie and I were deputed to explain to Professor Gregory, who was in attendance, that he was to be landed in control of a small party, if a safe and suitable place could be found, and to ask if he would accept these conditions. We reported his consent to the meeting, which was then adjourned for the consideration of other details.

Two of the representatives of the R. G. S., Sir Anthony Hoskins and Sir Vesey Hamilton, resigned shortly afterwards, explaining that they could not agree with the action of the Committee. The R. G. S. had, however, the right, which it subsequently exercised, of appointing new members.

At the adjourned meeting, on February 19th, the question of the ship wintering was discussed at length. Those who had practical experience of the Antarctic urged us strongly not to take the responsibility of permitting the ship to winter in the ice. Sir Joseph Hooker's statement of the danger was especially impressive, and the meeting decided in accordance with his opinion.

At the same meeting Major L. Darwin proposed to modify the conditions accepted by Professor Gregory, by adding to them the additional consideration that he should only be landed if the time of the ship should not be too greatly diverted from

geographical exploration. I protested strongly against any modification at this stage. Sir Michael Foster opposed me, and, after the close of the meeting, there was a somewhat sharp though friendly expression of conflicting opinions, he maintaining that there should be 'give and take,' I that we were already pledged to Professor Gregory, that the arrangement was as it stood a compromise—the minimum Professor Gregory would accept—by no means the one which scientific men, not belonging to the navy, would have preferred.

At that meeting Major Darwin did not succeed, but his suggestion in somewhat different words was again brought forward at the next meeting on March 5th. Just before the meeting Sir Archibald Geikie told me that he intended to support the proposed changes 'in the interests of peace,' and that Mr. Teall, and Mr. George Murray, Professor Gregory's representative, also approved them. Resistance was hopeless; I could only protest against any alteration of the conditions offered and accepted, requesting that my name and the names of those who agreed with me (Mr. J. Y. Buchanan and Captain Tizard) should be recorded.

I wrote to Professor Gregory a full account of what had happened, carefully explaining that his representative and many of his friends supported the changes, that I had confidence that the proposal was made to enable the Geographical Society to accept the instructions and that it was not intended to prevent, and, I believed, would not prevent, his being landed.

In spite of the incorporation of Major Darwin's changes the R. G. S. Council refused to accept the instructions, but addressed a letter signed by their President, dated March 18th, to the members of the Joint Committee stating that they were compelled, "as trustees for the money subscribed through their Society and for the funds voted by their Society, to regard the above scientific objects [viz., those to be carried out by a landing party] as subsidiary to the two primary objects of the Expedition—namely, exploration and magnetic observations." In view of the unanimous witness of all experts that the landing party was *essential* for full success in the magnetic work this statement is sufficiently remarkable.

The letter went on to inform us that the President, Sir Leopold McClintock, and Sir George Goldie had interviewed the officers of the Royal Society and had reported to the R. G. S. Council which now suggested that the Joint Committee should recommend a small committee of six, three to be appointed by each Council, to deal finally with the instructions. The Council of the R. G. S. agreed to accept the decision of this committee provided the Council of the Royal Society agreed to do the same.

It has been stated in various directions that the Geographical Society produced new evidence (based upon the experience of Borchgrevink and the intentions of the German leader) which had not been laid before the Joint Committee, and thus induced the officers of the Royal Society to agree to a new committee. To this it may be replied that these sources of information had been open to the Joint Committee, and that, if anything new had arisen, it was reasonable to refer it to the old committee rather than to a new one appointed *ad hoc.* Furthermore, the letter of the Royal Geographical Society, referred to above, clearly indicated that the real intention was to escape from the conditions proposed to and accepted by the Scientific Leader.

The Joint Committee met on April 26th, and was addressed in favor of the course proposed by the R. G. S. Council by Sir George Goldie. Nothing was said which could diminish the conviction that the R. G. S. Council and that of the R. S. in weakly

consenting to nominate a fresh committee had struck a disastrous blow at all future cooperation between scientific bodies in this country.

What reply could the officers make if they were asked to advise the Council of the Royal Society to cooperate with that of the Royal Geographical Society on any future occasion?

I felt justified in asking what guarantee was there that the Council of the Royal Geographical Society would accept the finding of the committee of six, when it had refused to accept that of a committee which included all the officers and almost every expert in Arctic and Antarctic exploration from both societies. In reply Sir Michael Foster, in spite of the promise of firmness held out by his attitude on February 12th, when Sir Clements Markham threatened that his council would repudiate the finding of the Joint Committee, maintained that they had only acted within their rights, and that the Royal Society Council claimed the right to do the same if it had not agreed with the decision.

At this point it will be convenient to give a list of the representatives of the Royal Society on the Joint Antarctic Committee, the representatives of the Royal Geographical Society being equally significant in relation to the council of their own society. They are the President, the Treasurer, the Senior Secretary, the Junior Secretary, Mr. A. Buchan, Mr. J. Y. Buchanan, Captain Creak, Sir J. Evans, Sir A. Geikie, Professor Herdman, Sir J. D. Hooker, Professor Poulton, Mr. P. L. Sclater, Mr. J. J. H. Teall, Captain Tizard, and Admiral Sir W. J. L. Wharton.

If the reports of Joint Committees of such magnitude and weight are to be thrown over with the approval of the councils of both societies because a majority of one council does not agree with the conclusions, men will rightly hesitate before consenting to devote an immense amount of time and trouble to the work of the Society, and the efficiency of the Royal Society will be greatly diminished.

The considerations set forth above indicate the future injuries which are likely to be inflicted on our Society by this surrender. At the meeting on April 26th, I was more concerned with the immediate and pressing injury, and therefore urged that the Royal Society was a trustee for the interests of science and that we had pledged ourselves to secure certain powers to the Scientific Director, that it was better the expedition should not start (a contingency contemplated as possible by Sir George Goldie, but not a serious danger, I believe, even though the Royal Society had stood firm and appealed to the Government, not on the subject-matter in dispute, but on the refusal of the Royal Geographical Society to work with the recognized methods of cooperation) than that the Royal Society should betray its trust, that the fellows of the Society would not support the officers in thus yielding to the Royal Geographical Society, and that I should feel bound to explain my position to the Society. Sir Archibald Geikie and Mr. J. Y. Buchanan also strongly objected to the surrender, which was then confirmed by a large majority of those present.

We were told by Sir George Goldie that the three representatives of the Royal Geographical Society on the new committee would be Sir Leopold McClintock, Mr. Mackenzie, and Sir George himself; by Sir Michael Foster that the Royal Society Council would appoint three non-experts, viz.: Lord Lister, Lord Lindley and the Treasurer, who could pronounce without bias upon the whole of the evidence. My colleague, Captain Tizard, with whom I had worked with the most complete sympathy and agreement through the whole course of the negotiations, supported the

formation of the new committee, because of Sir Michael's assurance that all evidence would be sifted and because of his faith in the validity of the evidence he had to give. Others probably voted in the affirmative for the same reason.

Without asking for evidence from Sir Joseph Hooker, Sir W. Wharton, Sir George Nares, Sir A. Geikie, Captain Creak, Captain Tizard or Mr. Buchanan, the new committee proceeded to cable to Melbourne the modifications which have led Professor Gregory to resign.

In bringing a condensed account of the negotiations before the Fellows of the Royal Society I desire to call attention to certain special difficulties which the Society has had to encounter in the struggle.

(1) The fact that nearly the whole of the money voluntarily subscribed was obtained through members of the Geographical Society and from its funds.

(2) The fact that Sir Clements Markham, President of the Royal Geographical Society, a man of remarkable energy, resource and resolution, was the chief antagonist of the amendments passed by the Joint Committee.

(3) The fact that the Junior Secretary and Sir John Evans were absent from England during the most critical period.

(4) Professor Gregory's appointment to the Chair at Melbourne, involving his absence from England during a large part of the negotiations.

Making all allowance for these difficulties, I believe that the majority of the fellows will consider that the claims of the scientific chief in an expedition undertaken to do scientlfic work have not received from the Royal Society that unflinching, undivided and resolute support which they would have expected and desired.

EDWARD B. POULTON.

OXFORD, May 15, 1901.

FIRST REPORT OF THE LIMNOLOGICAL COMMISSION OF THE AMERICAN MICROSCOPICAL SOCIETY.

THE initial report of a body so recently organized as this can hardly be more than preliminary in character, all the more so that the field entrusted to it is as extensive as untried. When, by the action of this Society a year ago, the Limnological Commission was organized and its members asked to assume the duties laid upon them in connection therewith, they accepted, not without some hesitancy at the extent of the work before them. The study of fresh-water bodies is indeed a great field, barely touched upon at one or two points in this country, and nowhere in the world even superficially covered as yet. Nevertheless it was the original field of biologic study; it was and is accessible to public and private workers practically everywhere, and affords opportunities for extended or limited work in any particular department of biologic research towards which the student may be drawn. Furthermore, to this work attaches an undoubted interest for all who come within its territory, while its problems have not only great biologic importance, but are also of economic value as well as of decidedly practical character, touching as they do upon the important questions connected with fish culture, municipal water supply and sewage disposal.

In this first report it will not be possible to do more than outline succinctly what has developed from our correspondence and discussion thus far regarding the object of the work, to make a brief survey of the field under discussion, of the ends to be reached and of some of the means for attaining them, and finally to invite propositions concerning the methods and problems under consideration and cooperation in proceeding toward their solution.

It may be fitting at the outset to state briefly the outlook before the Commission. Such a venture as this is not entirely unheard of and consequently venturesome. A similar body was appointed some years ago by the Swiss National Society of Natural Sciences. As a Swiss investigator,

Professor Forel, of Geneva, was the pioneer in the study of fresh-water lakes, and, as the investigators of this beautiful mountain republic have retained their supremacy in this field of research through more than thirty years, so also Switzerland was the leader in organized effort towards the development of limnological investigation. The plan of the Swiss Limnological Commission in assigning work in various regions to different students has met with such success as to inspire those who follow in its footsteps with hope for the outcome of their efforts, and as to hold up a high standard for their attainment. Similar results cannot be expected in a brief period of time, but we hope that they may be reached here eventually.

The study of limnologic questions affords abundant opportunities for workers of every type and of every grade; but if the results of such varied activity are to be of permanent value or of general import they must be correlated and unified. Therewith gaps in the records will become apparent and new problems will be suggested, so that the lines of work will be extended and at the same time joined together into a symmetrical system. The fundamental objects then of this Limnological Commission we believe to be:

To coordinate the results obtained by different investigators into a united whole, to enlist new workers and to encourage new work along lines already marked out, to suggest new lines of work and methods of research, and to aim at uniformity of procedure, so that the results may be compared and correlated.

For convenience in discussion and in the organization of the work, the field of limnologic study has been cut up into a number of main divisions and some of the chief subdivisions under each indicated. These are as follows:

1. Bibliography: A general historical review of limnological studies to date; periodic summaries of work done in the world at intervals thereafter.

2. Physiography: The inanimate environment, including the physical and chemical study of water bodies; types of such bodies, distribution; temperature, color, circulation; lake areas; composition of water, etc.

3. Biology, (*a*) Taxonomy of water organisms: Systematic tables, description and sketch of each on cards to form eventually a faunal catalog for the United States. (*b*) Morphology of organisms: Anatomy, histology, embryology of individual forms. (*c*) Distribution of organisms: Geographic; regional; littoral, limnetic, bathybic species; quantitative: General, numerical, proportional. (*d*) Physiology, experimental studies. (*e*) Ecology.

4. Applied limnology: Water supply, sewage, fish culture.

After this preliminary statement, the Limnological Commission has the following recommendations to make for the purpose of advancing this work:

First, it is expedient that as soon as suitable persons can be found who are willing to undertake the work, there should be added to the Commission a physicist, a chemist and a bacteriologist, in order that these phases of the environment may be adequately studied.

Second, the influence of the Society should be directed towards the production and publication of accurate systematic accounts of the fresh-water organisms to the end that the various workers on limnologic questions may have at hand taxonomic summaries of the organisms with which they come in contact. It is not too much to say that such treatises are non-existent for American forms and inaccessible to the majority, even for the few groups which have been partially worked out. This must be the first step in the inauguration of the proposed movement. The publication of a series of

catalog cards, each devoted to a single species, appears as a desirable method of putting such data into accessible form and keeping them in shape for frequent emendation or addition.

Third, in the interest of a complete knowledge of the distribution of fresh-water organisms, the Commission plans the keeping of careful faunal records. It is proposed to appoint one or two investigators for each group, who shall undertake to enter and collate all faunal records of this group which may be sent them and conversely to furnish workers with information concerning the distribution of such organisms. This plan will ultimately yield data for the discussion of the geographical distribution of fresh-water genera and species. It will also enable the elimination of such data as are common, leaving for publication by the student those facts which are important for one reason or another.

Fourth, the Commission is of the opinion that an occasional summary of progress in the field of limnology will serve to keep students in touch with the subject by giving them knowledge of the work of the world in general. This is that subdivision of the field which stands first in the outline given above. It has been covered sufficiently for the present by the summary and review printed in the *Transactions of the American Microscopical Society*, Vol. XX., bringing the subject up to January, 1899.

Fifth, the Commission would most strongly advise that individual work should be limited to a single body of water or to a definite problem studied with reference to a series of such water bodies. The results will be most useful for all purposes when they bear upon the thorough treatment of a single phase of the subject rather than more indefinitely upon a wider field.

There is naturally involved in the effort to carry out such plans as have been outlined some expenditure of money, even if the services of various investigators are freely and gratuitously placed at the disposal of the Commission. Accordingly, an appeal is made herewith to the generosity of those interested in the movement and in the development of biological study in our country for contributions, large or small, for the prosecution of this work.

In conclusion, all students interested in this subject are invited to participate in the work. It is by general and generous cooperation that success will be attained. The student who is working alone cannot advance far, unless brought in touch with others in the same field. It may be noted that the opportunity is peculiarly advantageous for those teachers in smaller colleges who can make use of a corps, even of untrained assistants, in the collection of various data. We feel it a privilege to invite kindly criticism of this report and suggestions as to the best means for carrying out the aims in view and for securing the cooperation of the largest number of workers.

(Signed) A. E. BIRGE, *Chairman.*
C. H. EIGENMANN,
C. A. KOFOID,
G. C. WHIPPLE,
H. B. WARD, *Secretary.*

NORTH CAROLINA SECTION OF THE AMERICAN CHEMICAL SOCIETY.

THE regular meeting of the North Carolina Section of the American Chemical Society was held in the State chemist's office, Agricultural Building, Raleigh, on April 27, 1901, at 11 A. M., with Professor Kilgore in the chair. Twenty-seven members and visitors were present.

The annual election of officers for the ensuing year were:

W. A. Withers, President; W. J. Martin, Jr., Vice-President; C. B. Williams, Secretary-Treasurer; Charles Baskerville, Representative in Council of the American Chem-

ical Society; Executive Committee, W. A. Withers, W. J. Martin, Jr., and C. B. Williams.

The following program was presented and discussed:

'Basis of Scientific Thought,' by CHARLES BASKERVILLE.

'The Chemical Composition of Cotton Seed Meal,' by W. A. WITHERS and G. S. FRAPS.

The authors found that the average amount of betain and cholin in seven samples of cotton-seed meal was 0.28 per cent., the ratios being (the average of two samples) betain : cholin :: 78.5 : 21.5. Gossypein if present is in minute quantity. Of the nitrogen-free extract 29.2 is pentosans, and 47.4 per cent. raffinose.

The pentosans of the meal are insoluble in diastase and are contained entirely in the nitrogen-free extract, unless an unusually large amount of hulls is present.

Cotton seed meal contains no starch and no appreciable quantities of sucrose or of reducing sugars. The average of five samples gave 0.48 per cent. of organic acids.

'The Recent Advances in Physiological Chemistry,' by A. S. WHEELER.

'Alcohol as an Antidote for Carbolic Acid,' by E. V. HOWELL.

1. In this paper attention was called to the fact that experiments by the author, beginning early in 1899, show that alcohol removes the escharotic effect of carbolic acid on the arm and in the mouth. 2. That, on account of the alarming increase in its use for suicidal purposes and the large number of accidents because of its general use as a disinfectant, carbolic acid should be scheduled as a poison in the poison laws of the various States and its sale restricted. 3. That alcohol is on record as an antidote and the results demand a thorough investigation. It must act most probably in one of three ways: (*a*) As a simple addition to counteracting the escharotic effect; (*b*) as a chemical antidote, forming an inactive or less active compound; (*c*) as a physiological antagonistic, its stimulating effect combating the depressant effect of the phenol. In investigations being carried on, so far no chemical reaction between carbolic acid and alcohol, or carbolic acid and camphor (which also removes the escharotic effect) has been observed.

'The Presence and Detection of Arsenic in Beer,' by W. GRIMES HAYWOOD.

This paper was a review of the recent cases of poisoning in England, due to the presence of arsenic in beer, and a comparison of the methods for the determination of that element.

'A New Meteoric Iron from Davidson county, North Carolina,' by JOSEPH HYDE PRATT.

This iron was found on a hillside rising just east of Lexington—Troy road, about a half-mile south of Cid P. O., Davidson County. The iron originally weighed 13 lbs. 14 oz., and was somewhat oblong in shape and its surface more or less pitted. Testing the polished surface failed to reveal either the Widemannstattian figures or the Neumann lines; but the etched surface presents a granular or stippled appearance overlain with a network of fine lines, and the fractured surface shows traces of what is apparently an octohedral cleavage. This etched surface, while being different from the other meteorites, is also different from any of the manufactured irons that have been tested. An analysis by Dr. Baskerville gave: iron, 93.89; manganese, .92; nickel, .30; cobalt, .34; silicon, .62; carbon, 3.88; but sulphur, phosphorus, titanium, aluminum and copper were absent. Dr. Pratt claims that the presence of nickel and cobalt and the absence of sulphur, phosphorus, etc., together with its structure and the more or less isolated country in which it was found, lead to the belief that this iron is of me-

teoric origin. The name proposed for it is the Cid Iron.

'Ulsch-Street Method modified to include Organic Nitrogen in Samples containing Nitrates and Chlorides,' by W. M. ALLEN.

The author recommends the following: Place 0.7 gram sample in 250 cc. Kjeldahl digesting flask. Add about 1 gram of reduced iron, 30 cc. water and 10 cc. dilute sulphuric acid (1 to 1). Shake well and let stand 15 or 20 minutes. Heat slowly, so that solution will boil gently for 10 or 15 minutes, then briskly, until two-thirds of water has boiled off. Cool slightly, add 25 cc. sulphuric acid and 0.7 gram mercuric oxide. Digest and distill, as in Kjeldahl method. In samples of pure nitrate, add 0.5 gram of ferric chloride to the water to dissolve first nitric oxide set free, and digest only for the nitric nitrogen. The presence of large amounts of iron salts must be guarded against or else violent bumping will give trouble in distillation.

'The Nature of Pentosoids and their Determination,' by G. S. FRAPS.

The author divides pentosoids into water-soluble, acid-soluble, soluble in cold caustic soda solution ('wood gum') and difficultly soluble. Members of the first three classes have been hydrolized to pentose, and are called pentosans. The last class includes lignocelluloses, oxycelluloses, etc., and have not been hydrolized to pentoses. The crude furfural from vegetable materials obtained in the pentosan determination was found to contain a body which is precipitated by phloroglucol and destroyed by distillation with hydrochloric acid. Its occurrence, distribution and digestibility were discussed and the effect of its presence on the pentosan determination.

'An Automatic Filter-Washer,' by J. M. PICKEL.

This apparatus consists of (1) a reservoir for water with which to wash; (2) a rubber tube, provided with thumb-screw clamps, leading from the reservoir to the (3) delivery vessel, which, by means of a small siphon, delivers the water intermittently on to the filter; (4) a funnel containing the filter and, set in this funnel, a smaller inverted funnel; (5) means for disposing of the washings. When once set going the apparatus needs no further attention, and is especially applicable in determining water-soluble nitrogen in fertilizers and also water-soluble phosphoric acid (although not yet in use for this latter purpose).

'Notes on the Latent Heat of Vaporization of Liquids,' by J. E. MILLS.

'Notes on the Determination of Insoluble Phosphoric Acid,' by C. D. HARRIS.

Mr. Harris exhibited an arrangement which had proved, in his hands, very satisfactory in filtering and washing citrate-insoluble phosphoric acid. He substitutes a carbon filter in the bottom of which is a porcelain disc covered with asbestos, for the slow and hazardous method of using a funnel and hardened filter paper.

'Contribution to the Chemistry of Thorium; Evidence pointing to the Existence of a New Element, Carolinium,' by CHAS. BASKERVILLE.

The author has obtained thorium salts from five different sources and purified them. By the action of sulphur dioxide on the neutral chlorides and by fractioning the citrates, oxides are eventually obtained which indicate the complexity of thorium. The pure oxide has a specific gravity of 9.8, according to some authorities, and 10.2, according to others. The purified oxide mentioned had a specific gravity of 10.1; after fractioning, one had a specific gravity of 9.4 and the other 10.37; intermediate fractions gave 9.6 and 10.4. Although atomic weight determinations have not been made, there is much evidence in favor of the existence of a new element, which the author would name 'Carolinium.' To avoid criticism the author stated his ex-

cuse for presenting the paper before the work was completed. Having made these observations quite four years ago, in the interim he has been engaged in securing direct from monazite sufficient quantity of pure thorium salts. Five thousand liters of solution have been worked up. The author's supply of the element has been much augmented through the kindness of Dr. Waldron Shopleigh, of the Welsbach Light Company, who presented him with two kilograms of his purest thorium oxalate. Last fall the author wrote Professor Bohnslar Brauner, of Prague, who had made the most recent atomic weight determinations of thorium, about his experiments. Not hearing from Dr. Brauner, the author was surprised to see in the *Proceedings of the London Chemical Society*, April 10, 1901, an article on 'Contributions to the Chemistry of Thorium' by Dr. Brauner, in which he states that he had fractioned thorium by hydrolysis of the oxalate into two bodies which he terms Thα and Thβ. Brauner's work as reported was by no means complete. While the author insists that he holds the very highest opinion of Professor Brauner, and while neither his work nor the motives prompting Professor Brauner in making this preliminary publication are called into question, in justice of the author's work along these lines, it was not deemed unscientific to present the results of incomplete observations.

'The Systematic Investigation of Soils,' by B. W. Kilgore.

After the transaction of some miscellaneous business the Section adjourned to meet in the summer.

C. B. Williams,
Secretary.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

We publish below a list of those who have been elected members in the Association and have completed their membership during the month of May.

Albree, Chester B., Mechanical Engineer, 14–30 Market Street, Allegheny, Pa.
Allan, Chas. F., Newburgh, N. Y.

Baldwin, Hon. Simeon E., Associate Judge of Supreme Court of Errors, New Haven, Conn.
Beach, Harry W., Manufacturer, Montrose, Pa.
Bethel, Ellsworth, Director, Department of Botany, Academy of Science, 271 Grant Ave., Denver, Colo.
Booth, Edward, Instructor of Chemistry, 1214 Harrison St., Oakland, Cal.
Brasefield, Prof. Stanley E., Professor of Mathematics, 327 Centre St., Easton, Pa.
Braunnagel, Dr. Jules L. A., Physician and Surgeon, P. O. Box 925, San Antonio, Texas.
Brown, Elisha R., President Stafford Savings and National Banks, 50 Silver St., Dover, N. H.
Bush-Brown, Henry K., Sculptor, Newburgh, N. Y.

Capp, John A., Mechanical Engineer, Schenectady, N. Y.
Carnegie, Thomas Morrison, Trustee of Carnegie Institute, Dungeness, Fernandina, Fla.
Chauvenet, Wm. M., Mining Engineer, 620 Chestnut St., St. Louis, Mo.
Clapp, D. C., Steel Manufacturer, 718 Amberson Ave., Pittsburg, Pa.
Clark, John J., Dean of Faculty, International Correspondence Schools, P. O. Box 534, Scranton, Pa.
Cleaver, Albert N., Manufacturer, South Bethlehem, Pa.
Clerc, Frank L., Professor of Metallurgy and Assaying, Colo. State School of Mines, Hotel Metropole, Denver, Colo.
Coit, Joseph H., St. Paul's School, Concord, N. H.
Cooper, James C., Tax Commissioner C. K. I. & S. P. R. R. Co., Room 5, Veale Block, Topeka, Kansas.
Cox, Prof. Ulysses O., Professor of Biology, State Normal School, Mankato, Minn.
Cummins, G. Wyckoff, Practicing Physician, Belvidere, N. J.
Currier, Mrs. Moody, Myrtle & Ash Sts., Manchester, N. H.

Dempster, Alexander, Engineering, Stanton & Euclid Aves., Pittsburg, Pa.
DuBois, Howard W., 4526 Regent St., Philadelphia, Pa.
Engler, Dr. Edmund A., President-elect Worcester Polytechnic Institute, Washington University, St. Louis.

Farquhar, Miss Helen, Teacher of Geometry, Algebra and Physics, Moravian Seminary, Bethlehem, Pa.

Frost, George H., Editor of *Engineering News*, 220 Broadway, New York City.

Galbraith, Prof. John, School of Practical Science, Toronto, Canada.

Graham, James C., Chemist, Phillips Academy, Andover, Mass.

Granville, Dr. Wm. A., Instructor in Mathematics, Yale University, 7½ Elm St., New Haven, Conn.

Grimes, Prof. James S., 122 Wesley Ave., Evanston, Ill.

Gold, Rev. Dr. James Douglas, Covington, Miami Co., Ohio.

Hall, Robert W., Biology, 2 Hillhouse Ave., New Haven, Conn.

Halsted, William Stewart, 1201 Eutaw Place, Baltimore, Md.

Hamaker, Prof. John I., Professor of Geology and Biology, Trinity College, Durham, N. C.

Harrison, Dr. Robert Henry, Practising Physician, Columbus, Colorado Co., Texas.

Henrich, Carl, Mining Engineer, Care of Union Copper Mining Co., Gold Hill, N. C.

Herr, Hiero B., Civil and Mining Engineer, 1246 Marquette Building, Chicago, Ill.

Herschberg, Hon. Michael H., Judge of Supreme Court, State of New York, Newburgh, N. Y.

Hill, Ebenezer, Treasurer, Norwalk Iron Works, South Norwalk, Conn.

Hillkowitz, Dr. Wm., Physician, 704 Race St., Cincinnati, Ohio.

Holmes, Frederic Harper, Instructor in Physics, Geography and Mathematics, State Normal School, Hyannis, Mass.

Hoobler, Bert R., Botanist and Zoologist, Wabash College, Crawfordsville, Ind.

Hooker, Donald R., Chemist, 436 Orange St., New Haven, Conn.

Hooper, Alcaeus, 710 Merchant's Bank, Baltimore, Md.

Hotchkiss, Henry S., Geologist, 55 Hillhouse Ave., New Haven, Conn.

Howland, Howard N., Lake Forest, Ill.

Keller, Edward, Ph.D., Box 724, Baltimore, Md.

Kelly, William, Mining Engineer, Gen. Mgr. Penn. Iron Mining Co., Vulcan, Mich.

Kendall, Hugh F., Mining Engineer, Care of Pittsburg & Lake Angeline Iron Co., Ishpeming, Mich.

Kindle, Dr. Edward M., Geologist, 109 Elm St., New Haven, Conn.

Kops, Julian de B., Civil Engineer, Savannah, Ga.

La Fetra, Dr. Linnaeus E., Physician, 58 West 58th St., New York City.

La Rue, Wm. G., Mining, North Freedom, Sauk Co., Wis.

Lauder, George, 7403 Penn Ave., Pittsburg, Pa.

Lockwood, Cornelius U., Teacher of Science, P. O. Box 15, Middle Hope, Orange Co., N. Y.

Macbeth, Geo. A., 717 Amberson Ave., Pittsburg, Pa.

Macdonald, Benjamin J., 296 Grand St., Newburgh, N. Y.

Marble, Milton M., Instructor in Physics, Hillhouse High School, New Haven, Conn.

Marvin, Walter T., Philosophy and Psychology, 39 Knox St., Cleveland, Ohio.

McKelvy, Dr. Wm. H., President Board of Education, 420 6th Ave., Pittsburg, Pa.

Morton, James F., Andover, N. H.

Negley, Henry H., Botanist, 600 N. Negley Ave., Pittsburg, Pa.

Ness, Prof. Helge, Botanist, A. & M. College, College Station, Texas.

Nicola, Frank F., Engineering, Cor. Wood & 6th Aves., Pittsburg, Pa.

Palmer, Dr. Charles S., Professor of Chemistry, University of Colorado, 1224 Pine St., Boulder, Colo.

Perkins, Albert S., Teacher of Chemistry, 75 Milton Ave., Hyde Park, Mass.

Platt, Dr. Walter B., Physician, 802 Cathedral St., Baltimore, Md.

Porter, Henry K., Trustee of Carnegie Institute, 541 Wood St., Pittsburg, Pa.

Rice, John A., Mining Engineer, Bland, Bernalille Co., New Mexico.

Richards, Alfred N., 45 West 60th St., New York City.

Richards, Prof. Charles R., Professor of Mechanical Engineering, Univ. of Nebraska, Lincoln, Nebr.

Roe, Edward Drake, Jr., Associate Professor of Mathematics, Syracuse Univ., 105 Anna St., Syracuse, N. Y.

Schweinitz, E. A. de, M.D., U. S. Dept. Agriculture, Washington, D. C.

Scott, William, Attorney-at-Law, 450 4th Ave., Pittsburg, Pa.

Sedgwick, Prof. Wm. T., Mass. Inst. Technology, Boston, Mass.

Shaw, Wilson A., Cashier Merchants' and Manufacturers' National Bank, Norwood Ave., cor. Forbes Ave., Pittsburg, Pa.

Sherman, Dr. Lewis, Physician, 448 Jackson St., Milwaukee, Wis.

Sherman, Franklin, Jr., State Entomologist, Raleigh, N. C.

Shropshire, Dr. Walter, Physician, Yoakum, DeWitt Co., Texas.

Silvester, Richard W., President, Maryland Agricultural College, College Park, Md.

Smith, Arthur, Lawyer, 152 Broadway, New York City.

Smith, Henry L., President, Davidson College, Davidson, N. C.

Smith, Miss Jennie M., 803 Arch St., Allegheny City, Pa.

Smith, Miss Matilda H., 803 Arch St., Allegheny City, Pa.

Smith, Miss Sara Winthrop, Botanist and Anthropologist, Nantucket, Mass.

Smith, T. Guilford, Civil Engineer, Regent University State of New York, P. O. Drawer, Buffalo, N. Y.

Snedaker, James A., Mining Engineer, 721–722 Equitable Bldg., Denver Colo.

Stevens, Edwin A., Mining Engineer, Victor, Colo.

Stevens, Geo. T., 33 West 33d St., New York City.

Stewart, Douglas, Mineralogist, Carnegie Museum, Pittsburg, Pa.

Stokes, Anson Phelps, 47 Cedar St., New York City.

Taylor, Edward B., Engineering, Pittsburg, Pa.

Thaw, Benjamin, President Hecla Coke Co., Morewood Place, Pittsburg, Pa.

Thomas, Dr. George T., Physician, Rogers, Texas.

Thompson, William, Mining, Metallurgical and Mechanical Engineer, care of Rossland Great Western Mines, Ltd., Rossland, B. C.

Thornber, John J., Botanist, 1217 Third Ave., Nebraska City, Nebr.

Vaile, Joel F., Lawyer, Denver, Colo.

Van Ornum, Prof. John Lane, Professor of Civil Engineering, Washington University, St. Louis, Mo.

SCIENTIFIC BOOKS.

THE MESOZOIC FLORA OF THE UNITED STATES.*

THE great activity in paleobotanical research which characterizes the work of the U. S. Geological Survey finds renewed expression in the recently issued 'Status of the Mesozoic Floras of the United States,' by Professor Ward, with the collaboration of Professor W. M. Fontaine, Mr. Atreus Wanner and Dr. F. H. Knowlton. Without attempting a republication of results which have already appeared, the author aims to present a 'succinct account of the progress thus far made in the direction of developing the Mesozoic Floras of the United States,' enumerating for the several formations, geographical areas and special localities the fossil plants that have been found, and also giving a complete bibliography of the work accomplished, with special reference to correlation. Questions of expediency have necessitated a division of the work into two parts. The first of these to which our attention is now directed discusses the Older Mesozoic, while the second part will deal with the Younger Mesozoic or Cretaceous.

The Triassic flora is represented by a description of seventy-six species or forms, of which nineteen are recorded for the first time, and among these latter is to be noted the name of a new genus—*Yorkia*—which has been given by Mr. Wanner and provisionally adopted by Professor Ward to identify a possible grass which is not very clearly defined as such by the figures given, although the latter are very suggestive of a plant of Monocotyledonous type which serves to recall the *Poacites* of Saporta.

The incompleteness of the paleobotanical

* Ward, Lester F., Status of the Mesozoic Floras of the United States. The Older Mesozoic. Second Annual Report of the U. S. Geol. Surv., 1898–99. Washington, 1900. Pp. 215–430. Plates XXI.–CLXXIX.

record, especially with respect to the earlier periods, and the uncertainty which exists relative to precise limitations as defined by the vegetation, lead the author to treat the American Trias as a geographical unit, between which and any of the recognized European series it has as yet been impossible to establish exact correlation, but it is worthy of remark that not only are the plants of the European Trias most numerous in the uppermost number of the series, *i. e.*, in the transition beds or the Rhetic, but that all the fossil plants of the American Trias have their nearest affinities in Europe, with those of the latter formation.

The principal plant-bearing deposits of the American Trias are to be found in the Connecticut Valley, near Richmond, Virginia, and in North Carolina. They are also extensive in New Mexico and Arizona, extending into Utah, Nevada and Colorado, and probably also into the Indian Territory and Texas. They also appear in California in the well-known beds at Oroville. The Pennsylvania area was very carefully studied by Mr. Wanner, whose material was revised by Professor Fontaine, and for a total of thirty-one species shows Filices 10, Equisetaceæ 1, Cycadaceæ 10, Bennettitaceæ 1, Ginkgoales 1, Coniferæ 7 and Monocotyledons (?) 1.

In the Virginia area the work of Professor Fontaine led Dr. Stur, of the Austrian Geological Survey, to identify many of the species with plants from the European Keuper, whence he concludes that the Trias of Virginia and that of Lunz are of the same age.

The most complete and noteworthy collection of plants from the older Mesozoic is that of Dr. Emmons from North Carolina, deposited in the museum of Williams College, where they were subsequently studied by Professor Fontaine with the result that it was found to contain Filices 10, Equisetaceæ 2, Cycadaceæ 14, Bennettitaceæ 1, Ginkgoales 1, Coniferæ 6 and of doubtful affinity 4, in a total of thirty-eight forms. Comparing this list with that obtained from Pennsylvania, a remarkable correspondence between the representatives of the different familes is here noted.

One of the most notable features of the southwestern area is to be found in the very abundant remains of trees which have become silicified and form the well-known 'Petrified Forest of Arizona.' These remarkably well preserved remains have already been fully described in a special memoir by Professor Ward, and they are now dealt with only so far as is necessary to connect them with the special subject under discussion. The wood has been identified by Knowlton as that of *Arancorioxylen Arizonicum*.

The Jurassic flora embraces a description of fifty-two species, of which three only are recorded for the first time. About half of these species are embraced in the Oroville flora of California and include Filices 13, Cycadaceæ 10, Ginkgoales 1, Coniferæ 3 and unknown 1; while the remaining twenty-four from the Jurassic of Wyoming represent Cycadaceæ 22, Coniferæ 2.

Of the 28 species in the Oroville flora, only 12 are to be regarded as of definite value in the determination of geological age. Of these *Cladophlebis spectabilis*, *C. arguluta*, *C. whitbiensis tenuis* var. *a*; *Thyrsopteris Maakiana*, *Podozamites lanceolatus*, *P. lanceolatus latifolius* and *Pinus Nordenskioldi* were determined by Heer to be characteristic of the Jurassic in a horizon equivalent to the Lower Oolite of Scarborough, whence it becomes of special interest to observe that Seward * refers to the occurrence of *Cladophlebis whitbiensis*, *Thyrsopteris Maakiana* and *Podozamites lanceolatus*. *Cladophlebis whitbiensis* he now recognizes as properly identical with *Todites Williamsoni* of Brongniart, a species of wide distribution in the Jurassic of Europe, Greenland and Siberia and characteristic of the Yorkshire Oolite. *Thyrsopteris Maakiana* he identifies with *Coniopteris hymenophylloides*, which occurs in the Jurassic of Siberia and also constitutes one of the most characteristic species in the Oolite of the Yorkshire Coast. *Podozamites lanceolatus* has an exceptionally world-wide distribution, and is especially characteristic of the Jurassic strata. The *Pagiophyllum* type of conifer which is highly characteristic of the Jurassic, is represented in the Oroville series by *P. Williamsoni* as the only conifer of importance; while in Europe and China, as also in the

* 'Catalogue of Mesozoic Plants,' British Museum, 1900.

Yorkshire flora, it is a characteristic element of the lower Oolite.

Sagenopteris Nilsoniana, while found in the Oroville flora, is most characteristic of the Rhetic, and it does not occur in the Yorkshire Oolite, where its nearest representative is *S. Phillipsi* of Brongniart. Its reference to the Oroville horizon is regarded by Ward with some doubt, hence it can not be held to have much weight as a factor in determining age.

The author concludes his valuable contribution by a tabular view of the distribution of 188 separate forms of Lower Mesozoic plants, showing their relation to the various North American areas both of the Triassic and Jurassic formations. He thereby gives emphasis to the fact that remarkably few species (three) are common to both formations, while even the majority of these are open to question. A comparison of the flora of the Yorkshire Oolite with the Jurassic of North America shows that with respect to the Filices and the Coniferæ there is a close correspondence in relative number of representatives, but that in the North American Jurassic there is a pronounced preponderance of the Cycadaceæ. In the latter flora also, both Bryophyta and Equisetales appear to be wanting.

	Inferior Oolite of Yorkshire.	North American Jurassic.

D. P. PENHALLOW.

MONTREAL, May, 1901.

Steam-boiler Economy. A Treatise on the Theory and Practice of Fuel Economy in the Operation of Steam-Boilers. By WILLIAM KENT, A.M., M.E. New York and London, John Wiley & Sons and Chapman & Hall. 1901. 8vo. Pp. xiv + 458. Price, $4.00.

This is a work, by an authority in its field, devoted to the study, theoretical, practical and experimental, of steam-boiler economics. Its author has had a long and varied experience of the most valuable kind in this department of mechanical engineering and in related fields of work, study and research. To this peculiarly happy practical and theoretical acquaintance with this subject he has added a singularly exceptional talent for the work and an unusually thorough technical preparation for its prosecution. Large experience, as an author and as an editor, and in the preparation of professional reports as expert in this and related matters, has given him the ability to digest, to formulate and to logically plan and execute a piece of technical work of high grade. The outcome of his endeavor is an exceptionally condensed, complete and exact treatise. The author has also confined himself very closely to his restricted title, and the reader will find there precisely what he seeks.

The book is not only well constructed, but it adds to existing knowledge, as presented in the text-books and special treatises as commonly written, some very valuable novelties which have peculiar interest to the professional man and the student. For example, maps are given of the coal-fields of the country and the distribution of the fossil fuels is exhibited clearly; while accompanying tables of composition, very full and officially endorsed, show what variations of quality occur as we pass from the graphitic anthracites of Rhode Island and Massachusetts, across the Pennsylvania beds over the remarkable deposits of West Virginia and into the Alabamian district, or across Ohio, Indiana and Illinois, Tennesse and Kentucky deposits into the regions of the friable fuels of the Rocky Mountains and to the Pacific Coast, with its extensive distribution of lean coals and lignites.

Mr. Kent has constructed some remarkably valuable as well as novel graphic illustrations of the laws connecting composition with efficiency with varying intensities of draught and variations of air-supply, and has done much to reconcile the widely differing conclusions of investigators in this department of scientific research, who are now coming to be numerous and industrious, commensurately with a growing recognition of the importance of the subject. He has given us a larger addition to our systematized knowledge, and has added to our obligations by introducing well-established and new and useful formulas and diagrams, expressing the relations of conditions bearing upon and

determining efficiency. The discussion of 'temperature and fire' is extended and good; that of the problem of smoke prevention, the account of the automatic stoker and the full elaboration of useful algebraic formulas are points of excellence deserving of special mention. The revelation of the effect of varying air-supply with variations of the rate of combustion is new and important as here presented, and the exposition of the value of flue-gas analysis is effected in an excellent fashion.

For a first edition, this seems exceptionally free from typographical or other errors, and it may be taken for granted that later editions will follow from which even these minor defects will be completely pruned.

The book-making is good, and the maps are printed upon a fine grade of paper to insure clearness. Many of the illustrations and nearly all the diagrams are new, and the whole constitutes a work which is likely to have extensive sale among professionals and professional schools. The mathematical work and the discussions of results of boiler-tests, of which the records are presented very fully, will find constant use.

R. H. THURSTON.

A Reader in Physical Geography. By RICHARD E. DODGE. New York, Longmans Green & Co. 1900. 12mo. Pp. viii + 237. Price, 70 cents.

It is gratifying to see the new point of view in physical geography coming into our education and our literature. The application of the theory of evolution to all branches of the subject has taken it bodily from the static condition in which it was conceived by our fathers, and reestablished it as a dynamic science, live and growing. There are no longer any 'everlasting hills,' but mountains and vales wax and wane, and record the histories of their mutations in the landscape so legibly that he who runs may read. And man comes on the scene, molded inevitably by the geographic environment in which his lot is cast, and in turn reacts upon that environment in many important ways. This is the outlook Professor Dodge has in his little volume. He has written it for beginners, and his fine quality as an instructor is in evidence on almost every page. He is very happy in his ability to interpret the principles of land sculpture in the most homely similes. The beginner not only may, he must, relate the new knowledge to what is already well known to him.

The topics treated are, The Continents, The Industries of Men, The Origin of Land Forms, The Great Land Forms, Climate and other important physical features influencing man.

The book is intended as auxiliary reading for beginners in physiography, but it will also make good reading for the laity in other lines, who wish to know the way in which a physiographer looks at his problems.

J. PAUL GOODE.

Air, Water and Food. By ELLEN H. RICHARDS and ALPHEUS G. WOODMAN. New York, John Wiley & Sons. Pp. 230. Price $2.00.

The first portion of the book covers the composition and impurities of air and their relation to human life. The problem of ventilation is dwelt upon, and very proper reference is made to the faulty argument so often advanced that, because carbon dioxide is heavier than air, that therefore the proper method of securing its removal from living rooms is to provide exits for it near the floor. The public forget that the gas, as the sanitarian meets it, is warm, not cold; and that, moreover, the principle of gaseous diffusion has caused a more or less complete mixture of all the gases present in the room.

Chapter IV. gives well stated methods for air analysis.

Some eighty pages are given to the subject of water, its source, properties, relation to health and the methods employed for its examination.

Following the directions for the 'determination' of each item in water analysis, there is found a paragraph entitled 'Notes,' wherein are given in a very acceptable form the sundry hints and cautions so necessary for the guidance of the beginner. An excellent statement is found on page 81, to wit: "The value of a water analysis is in direct proportion to the knowledge and experience of the one who interprets it."

Again, on page 66, "The conclusions are not infallible, but there are enough unavoidable

risks in human life without taking unnecessary ones."

This is very true. The analyst should ever stand between the public and a questionable supply, and the consumer, rather than the water purveyor, should be given the benefit of any doubt.

The book closes with a consideration of the adulteration and examination of milk, butter, cereals and fermented liquors.

The authors have had so large and varied an experience with the subjects upon which they write, that the excellence of the present contribution to sanitary literature was to have been expected. WILLIAM P. MASON.

SCIENTIFIC JOURNALS AND ARTICLES.

The Journal of Physical Chemistry, April. 'On an Improved Method of determining Latent Heat of Evaporation and on the Latent Heat of Evaporation of Pyridin, Acetonitril, Benzonitril,' by Louis Kahlenberg. Description of an improvement on the Berthelot apparatus for determining the latent heat of evaporation, in which the liquid is boiled by an electrically heated platinum spiral, and the results obtained by its use. 'A Class of Relations between Thermal and Dynamic Coefficients,' by George H. Burrows. 'Minumum Boiling-Points and Vapor Composition, II,' by Morris R. Ebersole. A study of acetone-benzene solution, with a classification of all mixtures of two solvents which have been studied, according to vapor-pressures and boiling points. 'On Clapeyron's Equation,' by Paul Saurel. 'Note on the Fundamental Equations of Multiple Points,' by J. E. Trevor.

IN the *American Geologist* for March, S. W. McCauley presents a discussion on the 'Trap Dykes of Georgia.' He states that they are all of the same age, and vary from an inch to two hundred feet in width and extend from a few rods to many miles. The 'Plan of the Earth and its Causes,' by J. W. Gregory, is continued from the February number, in which the writer concludes that the plan of the earth may be attributed to the unceasing shrinkage of its internal mass. Professor E. W. Claypole contributes some interesting notes on 'Petroleum in California.' 'Some Salient Features in the Geology of Arizona' is discussed by William P. Blake. This is followed by 'The Lake Systems of Southern Patagonia.' The author of this article divides the lakes into three classes—residual or salt lakes, glacial and tectonic. The April number contains a valuable contribution to the geology of 'The Piedmont Plateau of Georgia,' by Thomas L. Watson. The rocks of the region are divided into three different kinds, viz., the even-grained, massive granites, the porphyritic granites and the granite-gneisses. Of the even-grained granites, all but two possess biotite as a principal element, while hornblende is entirely wanting; the porphyritic granites are, with one exception, massive, with a composition somewhat similar to the massive granites, and in some places showing a gradation from one to the other; the granite-gneisses form extensive areas of schistose rock, similar in composition to the other two, and are believed to be metamorphosed eruptive granites. The author, after furnishing considerable proof, concludes that the region consists of eruptive granite which has been subject to the action of metamorphism and weathering, thus differentiating into the other two kinds of metamorphic rock. The age of the area is supposed to be Archæan, but it is crossed by numerous dykes of a later origin. Mr. Oscar H. Hershey contributes a paper entitled 'California Metamorphic Formations,' in which he describes the formations of the Klamath mountain region. He concludes that the schists of the upper region are somewhere between the Archæan and Devonian in age, and favors the earlier rather than the later date. This is followed by a paper, 'Fossils near Montreal,'

by Charles Schuchert, in which he describes the fauna of Saint Helena as from the Helderburg and the middle Devonic ages.

SOCIETIES AND ACADEMIES.

BIOLOGICAL SOCIETY OF WASHINGTON.

THE 340th meeting was held on Saturday evening, May 4th.

T. H. Kearney presented a paper on 'Loeb's Investigations into the Action of Ions upon Animal Structures, as supplemented by Studies with Seedling Plants,' quoting from Loeb's published papers at some length, special stress being laid upon their value as illustrating the theory of the rôle of ion-proteid compounds in vital phenomena. In experiments with animals it was the action of mixed solutions of two or more salts, as compared with that of each salt in a pure solution, which led to the development of this theory. The result of numerous experiments with seedling plants, as to the limit of concentration of solution which permitted the maintenance of vitality, agreed in many important points with the results obtained by Loeb in experiments with animals. In both cases salt solution was found to be highly toxic, while the addition of a second salt in many cases largely neutralized this poisonous effect and notably increased the degree of concentration of the more toxic salt in which root tips could survive during a twenty-four hours' culture.

Experiments were made with salts of magnesium (sulphate, chloride), of sodium (carbonate, sulphate, chloride and bicarbonate) and calcium chloride, all of which are important components of 'alkali' soils in the western United States. In pure solution they proved toxic in the order named, the limit of endurance for magnesium sulphate being approximately a $\frac{1}{080}$ normal solution, that of calcium chloride a $\frac{1}{4}$ normal. Mixtures were made of equal volumes of definite concentration of each two of these readily soluble salts, and of each of them with the comparatively insoluble magnesium carbonate, calcium carbonate and calcium sulphate, which are likewise abundant in the alkali soils.

In several cases addition of a sodium to a magnesium salt considerably raised the limit of concentration of the latter endurable by the roots of the white lupine (*Lupinus albus*), but the most striking results were obtained by the addition of calcium, either as chloride or sulphate, to magnesium and sodium salt solutions. Calcium sulphate, added in simple excess of the powdered salt, proved extraordinarily efficacious in neutralizing the toxic effects of other bases, increasing the maximum endurable concentration for sodium sulphate from $\frac{3}{400}$ to $\frac{1}{2}$ normal, and for magnesium sulphate from $\frac{1}{800}$ to $\frac{3}{5}$ normal.

In a $\frac{2}{5}$ or $\frac{3}{5}$ pure solution of magnesium sulphate the root cells were strongly plasmolyzed, while in a corresponding solution plus an excess of calcium sulphate no trace of the plasmolyzing action could be detected. The effect of calcium sulphate upon the corresponding chlorides was much less marked. Hence, while in some cases the effects of mixtures could be ascribed to the kations (basic radicle) alone, in others it seems clear that the anions are also able to make their influence felt. Hydroxyl ions, dissociated in very dilute solutions of sodium carbonate (Na_2CO_3), and sodium bicarbonate ($NaHCO_3$), markedly stimulated the growth of the roots, just as Loeb found them to stimulate the gastrocnemius of frogs, to absorption of water from, and rhythmical contraction in, a sodium-chloride solution.

The results of this investigation, which was undertaken at the request of the Chief of the Bureau of Soils of the Department of Agriculture, are to be described in a forthcoming bulletin of the Division of Vegetable Pathology of that Department. They are believed to have considerable economic significance, apart from their bearing upon the question of the influence of ions upon organisms.

Under the title 'A Kinetic Theory of Evolution,' Mr. O. F. Cook suggested, on the basis of studies in the Diplopoda and other groups, that evolution be interpreted as a kinetic phenomenon or process of gradual and spontaneous accumulation of variation instead of a reaction to external conditions. It was also held that the differentiation of species is a process quite distinct from evolutionary progress, and that selection and isolation may conduce to the

former while retarding the latter. In this view evolution would be favored by interbreeding rather than by segregation, and natural selection would be an incident rather than a cause of evolution. Diversity was shown not to be conditioned upon segregation, but to be distinctly favored in the economy of species. Under a kinetic theory the origination and inheritance of characters represent but different statements of the same facts, and the predication of a 'hereditary mechanism' is unnecessary. Evolution is not confined or directly connected with any one type of cells or method of reproduction, but is a general property of protoplasm; it is not only a cellular or cytological, but a supracellular or organic, process; evolutionary theories must accommodate both unicellular and compound individuals, and even treat as evolutionary units the colonies of the social insects.

F. A. LUCAS.

CHEMICAL SOCIETY OF WASHINGTON.

AN adjourned meeting was held in Hopkins Hall, Johns Hopkins University, Baltimore, Md., on April 27th, when the following program was presented: 'The Lowering of the Freezing Point of Aqueous Hydrogen Dioxide,' by H. C. Jones. The author stated that an attempt was made to measure the dissociating power of hydrogen dioxide by means of the conductivity method. This method was abandoned, since all the metals used as electrodes decomposed the dioxides, even at zero degrees. The lowering of the freezing point of aqueous hydrogen dioxide by certain salts was measured and was found to be less than the lowering of the freezing point of water, under the same conditions.

'The Preparation of Semi-Permeable Membranes for the Demonstration of Osmotic Pressure,' by Professor H. N. Morse. The author referred to the difficulties encountered in the preparation of osmotic cells by the method of Pfeffer, and stated the results of some preliminary experiments, undertaken in cooperation with Dr. D. W. Horn, in attempting to overcome these difficulties. Instead of expelling the air from the walls of the cups by immersion in water and exhaustion with an air-pump, as is done in the method of Pfeffer, electrical endosmose was employed, the cup being immersed nearly to the top and filled with a dilute solution of potassium sulphate, then surrounded by a cylindrical electrode and another one placed inside. A one-ampere current was passed through the solution for 15 minutes, from the outer to the inner electrode, causing a rapid passage of liquid through the walls of the cup and freeing them from air. The cup was then removed, emptied, rinsed and placed in water until used for the formation of membrane. The method described by the author was as follows: A cup whose walls had been freed from air and filled with water was placed in a solution of a copper salt and filled with a solution of ferrocyanide. A current was passed from the outside inward, the copper and ferrocyanogen ions being driven into the walls from opposite directions; a membrane was built up wherever they met. The results were very satisfactory. The method of construction of the electrodes was described and the resistance of the cups stated. On breaking the cup, the membrane was found as a reddish brown line, usually in the middle of the wall, though deviating more or less to one side or the other.

'Molecular Rearrangement of Sulphamine Acids,' by Dr. Ira Remsen.

'On a Reduction Process for Tin at Comparative Low Temperatures, and Recovery from Waste Products,' by Chas. Glaser. This paper gave a description of a process invented by John C. Toliaferro for the recovery of tin from waste products. The refuse from tin-plate works consists of the remnants of the fatty acids used to protect the black plates from reoxidation after cleaning with acid, and more or less oxidized tin, which often contains some free metal or mixed oxides of tin and lead. The refuse from the oils often contains oxides of the two metals, which are usually recovered by burning off the oil and collecting the residue and metallic fumes. The united dross is reduced to metal in a suitable furnace. Mr. Toliaferro observed that under certain conditions he obtained metallic tin from the refuse fatty acids by heating them to incipient decomposition. Certain experiments were made showing that at a temperature a little above the melting point of tin, stannous soaps are reduced to metallic tin,

gaseous products and some carbon. From these observations the following reduction process was evolved: A large iron pot is heated from below, so that a piece of tin dropped at the bottom will melt. The pot is then filled with refuse fatty acids and the heat increased until they commence to give off vapors. Stannic dross is then introduced with stirring. This may be continued at pleasure or until the fatty acid is almost used up. The reduced tin is removed at convenient intervals.

'On Dr. Theodore Meyer's Tangent System of Sulphuric Acid Chambers,' by Chas. Glaser. The author described a modification of the construction and working of lead chambers used in the manufacture of sulphuric acid. The modification relates to the shape of the chambers and the motion of the gases. Ordinarily the chambers are square and the gases introduced in such a way that they traverse the chambers but once, get only moderate mixing, except where they fall upon the chamber curtains and where they are forced through relatively narrow connecting pipes between chambers. In the modification described, the chambers are round or polygonal, the gases are introduced near the ceiling in the direction of a tangent, and are removed through the center of the bottom by suitably constructed pipes. Experiments show that the gases move first along the sides of the chamber, drifting towards the center in such a way that the whole content gets into rotation. Cooling and draught bring the whirlpool in the center to the exit pipe. When introduced into the second chamber, the gases retain the revolving motion derived from the first, to which is added the motion of the second, so that an epicycloid motion is produced. The gases traverse the chambers a good many times, increasing largely the amount of work performed. It has been demonstrated that by this method the necessary chamber space for one pound of sulphur in twenty-four hours is reduced to below ten cubic feet as against twenty in the old system. The author stated that the cost of producing sulphuric acid, so far as labor and lead chambers are concerned, is reduced to fifty per cent. of what it was by the old method.

'The Solubility of Gypsum in Aqueous Solution of certain Electrolytes,' by Frank K. Cameron and Atherton Seidell.

This paper gave a description of the complete solubility curves for gypsum in aqueous solutions of sodium chloride, magnesium chloride, calcium chloride, sodium sulphate and a mixture of sodium chloride and calcium hydrogen carbonate at 25° C. With sodium chloride and magnesium chloride the curves show maximum points. The formation of complex ions the authors believe to be possible and probable, but the deviations from the *mass law* are more likely to be due to a condensation of the solvent itself.

With sodium sulphate it was shown that the solubility of the gypsum first decreased and then increased, with increasing concentration of the more soluble salt, until it became greater than in pure water. It is believed that a double salt was formed in the solutions, possibly identical with the mineral glauberite. It did not separate from the solutions on evaporation, however, at ordinary temperatures. Here again the authors think the condensation of the solvent probably plays an important rôle and, under such circumstances, it is probable that the sodium sulphate dissociates to a large extent or completely as a di-ionic electrolyte. The composition of the solid phase, containing both calcium sulphate and sodium sulphate, did not apparently affect the composition of the solution in contact with it. This is regarded as of sufficient interest to merit further investigation. In solutions of calcium chloride the solubility of the gypsum decreases quite rapidly at first, and then very slowly but steadily as the concentration of the more soluble salt increases.

When calcium carbonate in the solid phase was also in contact with solutions of sodium chloride, and was brought to equilibrium with ordinary air, it was found that up to concentrations of about 80 grams per liter of sodium chloride, the gypsum dissolved in very nearly the same quantities as though the calcium carbonate were not present. From this point on, however, the curve makes a sudden drop and then the solubility of the gypsum slowly decreases.

Applications of the results to geological and technical studies were indicated, and a theoreti-

cal discussion accompanied the description of the experiments.

'The Solubility of Calcium Carbonate in Aqueous Solutions of certain Electrolytes and in Equilibrium with Air,' by Frank K. Cameron and Atherton Seidell:

Since the solubility of the calcium carbonate is dependent upon the amount of carbon dioxide in the gas phase in contact with the solution, the solutions were brought to equilibrium with air, previously washed in dilute sulphuric acid, and bubbled through the solutions by means of an aspirator. It was found that the curve for sodium chloride presented a well-marked maximum point. No normal carbonates were in the solution, the calcium dissolving entirely as the hydrogen carbon.

In sodium sulphate solutions, the major part of the calcium dissolved as the hydrogen carbonate, though at the higher concentrations normal carbonates were also found. The curve for this pair of electrolytes showed no maximum point. Curiously, it was found that calcium carbonate was much more soluble in solutions of sodium sulphate than in solutions of sodium chloride, at all concentrations.

The presence of solid gypsum was found to produce an effect on the solubility of calcium carbonate in sodium chloride solutions, greater in amount but similar in nature to that produced by calcium carbonate on the solubility of the gypsum in sodium chloride solutions, and described in the preceding paper. Practical applications of the work were pointed out and a theoretical discussion of the results obtained was given.

L. S. MUNSON,
Secretary.

TORREY BOTANICAL CLUB.

AT the meeting of the Club on March 27, 1901, the first paper of the evening was by Dr. John K. Small on 'The North American Genera of Mimosaceæ.' Dr. Small exhibited a uniform series of diagrammatic drawings, illustrating the flowers and fruit of each of these genera, and explained his proposed classification, replacing the previous artificial grouping. The variability of the fruit in valves, margins and cross-partitions was commented on. Discussion of the common sensitive plant followed, in which it was remarked that the sensitiveness to shock is so delicate as to be stimulated by holding a burning-glass near, or by drops of rain-water on first falling, or by holding a sponge of ammonia or of chloroform near. The utility seems unknown, except as the hot sun setting the leaves on edge prevents injury from intense sunlight. Sachs's suggestion was that the depression of the leaves served as a protection from hail; but it now appears that the native center of the plant is chiefly in the Orinoco regions where hailstorms are unknown. Much energy is exhausted by folding, and it is well known that the greenhouse sensitive-plants are frequently worked to death by repeated irritation.

The second paper, by Dr. Rydberg, soon to be printed, was on 'The Oaks of the Rocky Mountains,' in which region eleven species were described in Sargent's 'Silva,' a number now increased by Dr. Rydberg to twenty-eight.

E. S. BURGESS,
Secretary.

THE ONONDAGA ACADEMY OF SCIENCE.

THE 47th regular meeting was held in the Historical rooms, Friday P. M., May 17, 1901.

The first paper was by Dr. John Van Duyn, entitled, 'The Terrestrial Life of Porto Rico.' Dr. Van Duyn spoke entertainly concerning many facts and observations made during his recent visit, as the deep blue of the ocean, the appearance of different constellations, the character of the rocks and their probable formation, the differences in wind and climate of the northern and southern shores of the island, the animal and plant forms, and the inhabitants. The latter are a mixture of Spaniard, negro and native Indian. Although it has been maintained by high authority that the Indian types have been entirely lost, Dr. Van Duyn was positive that this was not so. He believes that the race possesses vast capabilities for development.

A second paper, entitled 'The Marine Life of Porto Rico,' was given by Dr. C. W. Hargitt, of Syracuse University. He briefly narrated the early work in the natural history of Porto Rico and then told of the recent expedition of the *Fish Hawk* to those waters, and of the

material thus collected. The fishes have already been described in the Report of the U. S. Fish Commission just published; and of the other forms which were sent to the various universities for examination and study, Dr. Hargitt reported on the material received here. The collection comprises the 'Alcyonaria,' and among the forms were several genera new to American waters, and six species new to science. The descriptions of all these will be published in the Reports of the Fish Commission during the present summer.

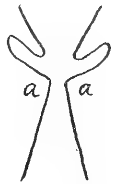
PHILIP F. SCHNEIDER.

DISCUSSION AND CORRESPONDENCE.

THE LARYNX AS AN INSTRUMENT OF MUSIC.

IN the *American Journal of Science* for April, 1901, Vol. XI., p. 302, an account was given of some speech curves that confirm the view that vowels are usually produced by intermittent puffs of air and not by vibrations of the form generally supposed. The following conclusions were reached: (1) The movement of the air in the mouth cavity is a free vibration and not a forced one; (2) the impulses from the larynx in making vowels are of the nature of explosive openings or sharp puffs of air. It was shown that the characteristic mouth tones in vowels are generally inharmonic to the larynx tone. The elaborate vowel tracings of Professor Hermann (Königsberg) and the late ones of Dr. Pipping (Helsingfors) had already proved that in song the mouth does not reinforce an overtone of the cord; my curves showed the same condition for ordinary speech. Similar results have been obtained by Boeke (Alkmaar), Bevier (New Brunswick), Donders (Utrecht), Merritt (Cornell), Samojloff (Moscow), and others, and can be seen in plates published by Nichols and Merritt (Cornell). The proof is on all sides complete and incontestible that Willis's theory ('Camb. Philos. Trans.,' 1830) of vowel formation is the correct one and that the theory of Wheatstone ('Lond. and Westm. Rev.,' 1837) is erroneous. Although the adoption of the Wheatstone theory led to numerous investigations and secondary hypotheses by Grassmann, Helmholtz and others, its phonetic difficulties were never overcome.

It was also pointed out that the structure of the larynx practically forbids any consideration of the vocal bands as membranous reeds. The accompanying figure is an outline section of the



vocal muscles (*aa*) whose vibrations produce the tone in song and speech. They bear no resemblance in structure or action to membranous reeds. When they are brought together by the action of the arytenoid cartilages, they close the passage of the larynx until forced apart by the air pressure. When this occurs a puff of air is emitted and they close again. The sharpness or smoothness of the puff is regulated by the contraction of the various portions of the thyro-arytenoid muscles which compose the vocal bands. The puffs in their physical forms resemble those that can be produced by a siren disk with differently shaped openings (Seebeck).

Structures of the nature of the vocal bands yield to the air pressure and vibrate wholly or mainly by a side movement, and not by the flap or lateral movement of membranous reeds. Professor Ewald (Strassburg) has illustrated their action by constructing cushion pipes. That the vibratory movement affects the bands through most of their depth is shown by the nodal lines seen with the laryngo-stroboscope of Oertel (Munich). Helmholtz's statement: "Im Kehlkoffe spielen die elastischen Stimmbänder die Rolle membranöser Zungen. Sie sind von vorn nach hinten gespannt, ähnlich den Kautschukbändern * * *," was based on the anatomical and physiological knowledge of the time at which he wrote the first edition of the 'Tonempfindungen.'

Professor Le Conte (California) in SCIENCE for May 17, N. S., Vol. XIII., p. 790, points out that he had already said that the larynx 'cannot be likened to a stringed instrument nor

to a reed-pipe,' and suggests the resemblance between the vocal band action and the lip action in blowing a horn. Whether the lips in blowing a horn vibrate laterally as reeds or by compression as cushions, I am unable to say; they may quite possibly vibrate in a manner different from that assumed by Helmholtz.*

E. W. SCRIPTURE.

YALE UNIVERSITY,
NEW HAVEN, CONN.

PHYSIOLOGY IN THE SCHOOLS.

TO THE EDITOR OF SCIENCE: Judging from the letter of S. W. Williston in your issue of May 24th, people must acquire their mental growth much more rapidly in Kansas than they do in the East. If I were confronted in an examination for the degree of doctor of philosophy with the question 'Why does the human body cease to grow about the twenty-fifth year?' I should think there were strong grounds for suspecting the examiner of endeavoring to show what I did not know, even at the price of asking questions whose answers I could not know. Yet we are told that this question has been asked of candidates for the State teacher's certificate. The theory of accelerated mental development is furthermore strongly supported by the apparent fact that children are expected, by the time they finish with the grammar school, to know about pleurisy, the respiratory center, residual air, appendicitis, *meatus auditorius* and the *motores oculi*.

If mental development is anywhere as rapid as these facts would suggest, there can, of course, be no criticism with regard to the consideration of these questions in physiology at the time indicated.

If, however, children generally show about the same rate of mental development as I have observed in the East, the writer would like to suggest that if less time were consumed in the contemplation of useless details of anatomy, relieved by worse than useless rambles into pathology, and more in the plain, common sense, practical study of the conditions of healthy living, teachers would no longer learn in examination papers that 'the body should be bathed frequently, should be bathed at least once a year.' There is, in fact, a horrible suspicion in the mind of the writer that something else than the text-book is at fault.

THEODORE HOUGH.

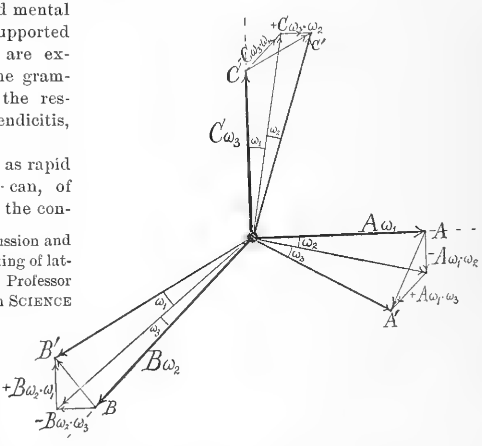
SHORTER ARTICLES.

THE GENERAL EQUATIONS OF ROTATION OF A RIGID BODY.

AFTER writing my brief note on the top,* it occurred to me that the same method might be



used to derive the Eulerian equations of rotation briefly and at once, in a way almost pic-

* Misunderstanding the point under discussion and supposing that Professor Le Conte was speaking of lateral vibrations of the lips and vocal cords, Professor Webster (Clark Univ.), replies to him in SCIENCE for May 24, N. S., Vol. XIII., p. 827, that the action of the lips and the vocal cords had already been explained by Helmholtz and that his description of 1862 'has never needed any improvement or correction.' Professor Webster asserts that he regards the simple *model* of a membranous reed pipe with a sheet of rubber in lateral vibration as 'a very convincing demonstration of the mode of action of the larynx.' He also classifies elastic cushions as 'reeds.'

* This Journal, May 31, 1901.

torially lucid as to the meaning of the terms involved.

Let A, B, C, be the principal axes of inertia and ω_1, ω_2, ω_3, the angular velocities of the rigid body around them. All this is kinematic.

Let A', B', C', be the positions of these axes a unit of time later. Lay off the angular momenta, $A\omega_1$, $B\omega_2$, $C\omega_3$, along these axes in order, as shown. Then will AA', BB', CC', be the corresponding per second changes of angular momentum.

Resolve each of these into components parallel to the original axes, and bring those belonging to the same axis together, viz.,

$$\begin{matrix} -B\omega_2\cdot\omega_3, & -C\omega_3\cdot\omega_1, & -A\omega_1\cdot\omega_2, \\ +C\omega_3\cdot\omega_2, & +A\omega_1\cdot\omega_3, & +B\omega_2\cdot\omega_1, \end{matrix}$$

remembering that as each axis rotates about the other two, the component displacements per second will be

$$\omega_2,\ \omega_3;\ \omega_3,\ \omega_1;\ \omega_1,\ \omega_2.$$

Add to the component changes of momentum found, the direct per second changes of angular momentum around the respective axes, viz.,

$$+A\dot{\omega}_1, \qquad +B\dot{\omega}_2, \qquad +C\dot{\omega}_3.$$

Let L, M, N, be the torques around the three axes in order, and equate these to the *total* per second change of angular momentum corresponding to the same axes. In other words, after adding each of the three columns,

$$L = A\dot{\omega}_1 - (B-C)\omega_2\omega_3,$$
$$M = B\dot{\omega}_2 - (C-A)\omega_3\omega_1,$$
$$N = C\dot{\omega}_3 - (A-B)\omega_1\omega_2.$$

C. BARUS.

ON A CRINOIDAL HORIZON IN THE UPPER CARBONIFEROUS.

FOR more than half a century the Lower Carboniferous limestones of the Mississippi valley have been justly celebrated for their enormous wealth of crinoidal remains. On this account, they have become widely designated as Encrinital limestones, a title which has long since assumed a distinctive value.

The crinoidal element in the faunas of the Lower Carboniferous has been further emphasized by the apparent extreme paucity or entire absence of crinoid remains in all other parts of the Carboniferous section of the region. The few species described were few in number, from widely separated localities and from very fragmentary material.

Unusual interest was, therefore, aroused a few years ago by the discovery, in the Upper Carboniferous rocks of the Missouri river, of a formation so rich in fossil crinoids as to merit the title Encrinital as appropriately as any terrane of the Lower Carboniferous. Species were not only new and numerous, but individuals occurred in the utmost profusion, their stems and long, slender, beautifully pinnulated arms intertwining as intricately as the richest of flowing arabesques. Moreover, the state of preservation was wondrously perfect. From a morphological standpoint the discovery was one of the most important ever made.

The geological position of this rich crinoid fauna is a short distance above what is called the Lower Coal Measures. It is in the terrane now known as the Thayer shales, the base of which is a stratigraphic level not much over 600 feet above the Lower Carboniferous limestones. The Thayer shales are in the lower part of the Missourian series. They are dark blue in color, and lithologically are indistinguishable from the Crawfordsville Shales of Indiana, which have been so prolific in crinoids in fine state of preservation.

The biological peculiarities of the crinoids from the Thayer shales as compared with those of the nearest forms from the Lower Carboniferous are noteworthy features. For two faunas so closely connected in space the differences are so profound when apposed to the resemblances as to be almost inexplicable.

But a satisfactory solution of the remarkable problem has been lately supplied from a source other than the biotic. The recently worked-out stratigraphy of the region throws light upon it in an unsuspected manner. The actual position of the Thayer shales, instead of being removed only 600 feet from the Lower Carboniferous limestones, are, stratigraphically, thousands of feet away.

While the lower coal measures have long been known to rest unconformably upon the underlying rocks, the stratigraphic break has been regarded as merely local in nature. Of late, the real significance of this hiatus has been

adjudged. A depositional equivalent has been found in a neighboring State. In central Arkansas, the unconformity is now discovered to be represented by no less than 20,000 feet of sediments. The real values of the new relationships of the horizons are better shown by a rectified general geological section of the Carboniferous of the region.

WESTERN INTERIOR SECTION.

Series.	Terrane.	Thickness.
Oklahoman.	Not here differentiated.	1,500
Missourian.	Cottonwood limestone.	10
	Atchison shales.	500
	Forbes limestones.	25
	Platte shales.	105
	Plattsmouth limestones.	30
	Lawrence shales.	265
	Stanton limestones.	35
	Parkville shales.	75
	Iola limestone.	30
	Thayer shales.	50
	Bethany limestones.	75
Des Moines.	Marais des Cygnes shales.	250
	Henrietta limestones.	50
	Cherokee shales.	200
Arkansan.	Not here differentiated.	20,000
Mississippian.	Not here differentiated.	1,500

Of these five series of the Carboniferous system, the Oklahoman represents the so-called Permian; the next three the coal measures; and the Mississippian the Lower Carboniferous. Measured in sediments, the horizon of the Thayer crinoids is far up in the Carboniferous, instead of being near the base. At Kansas City, where the crinoids were found, the Arkansan is represented by the hiatus—a period of vast erosion in that locality.

CHARLES R. KEYES.

THE PROCESS OF FREEZING IN PLANTS.

IN text-books on plant physiology, and in original articles upon the effects of freezing in plants, or on allied subjects, so far as is known to the writer, there is no working explanation of the process. The matter is referred to by Detmer and Moor, Vines, Haberlandt, Sorauer, Sachs and many others, but without detailed explanation.

The cells bounding the intercellular spaces (in leaves) are always moist on the side in contact with the air. As cooling goes on, all the tissue, contents of the cells and all, are contracting; but when a temperature of about 4° C. is reached, the water content of the cell begins to expand, while the wall goes on contracting. This forces more moisture into the intercellular spaces. When the freezing point for water is reached, ice crystals begin to form outside of the cell in the intercellular spaces. The ice crystals will form first here, because water has a higher freezing point than the solution within the cell. As cooling goes on, and further crystallization takes place, the freezing water gives off its latent heat which tends to keep, for a considerable time, the cell contents from freezing. The crystallizing water without the cell extracts water from the cell by an inherent attractive force which the molecules of the mother crystal have for its liquid. This force is the cause of further water being drawn from the cell to build up the crystal of ice, and this attractive force is a similar one to that which causes plasmolysis in the case of the common experiment with cells of *Spirogyra* and a solution of sodium chloride. The ice forms first in the intercellular spaces and continues to form there until the cell contents become frozen.

If a leaf so frozen be subjected to a higher temperature, water will be formed in the intercellular spaces, resulting in a translucent, 'water-logged' appearance of the tissue of the leaf. If, however, the temperature be raised very gradually, the cells will probably resorb the extracted water as rapidly as it is formed, resulting in no permanent injury to the leaf. Sachs found that the leaves of the beet and the cabbage frozen at from — 4° C. to — 6° C., and thawed in air at 2 to 3° C., were killed, while when thawed slowly in water at 0° C. they survived.

If the temperature be low enough and be continued long enough a permanent injury would result, for then the cell contents would become solidified.

In the case of the experiment with a beet partially scooped out and subjected to a freezing temperature, the formation of ice in the cavity is brought about in exactly the same way as it is in the intercellular spaces in leaves of plants, excepting on a larger scale. If the

freezing of the beet be brought about slowly, water may be drawn into the cavity from a considerable distance from cell to cell within the tissue.

Certain strong non-poisonous solutions, when applied to the cut ends of the petioles of leaves, produce a similar translucent effect in the tissue of the blades of leaves, as is shown by the writer in a paper now in process of publication.

JAMES B. DANDENO.
BOTANICAL MUSEUM OF HARVARD UNIVERSITY, May 22, 1901.

THE AMERICAN MATHEMATICAL SOCIETY.

A PRELIMINARY circular, which has just appeared, describes the arrangements which have been made for the summer session of the American Mathematical Society to be held at Cornell University, Ithaca, N. Y., during the week beginning on August 19th. The meeting proper, for the transaction of business and the presentation of papers, will take place on the first two days, while the remainder of the week will be occupied by a colloquium. Two courses of lectures by Professor Oskar Bolza, of the University of Chicago, and Professor E. W. Brown, of Haverford College, are announced as the basis for this colloquium, which will be the third organized by the society in connection with its summer meetings. Professor Bolza's subject is 'The calculus of variations, in particular Weierstrass's discoveries.' The principal object of the course is to give a detailed account of the solution of the simplest type of problems, in its historical development, with special emphasis upon the contributions of Weierstrass and his followers. A summary review of the peculiar features of the more general problems is also intended. Professor Brown will lecture on 'Modern methods of treating dynamical problems and in particular the problem of three bodies.' The object of this course is to set forth some of the later attempts to introduce more rigor into the methods of solving dynamical problems, mainly the researches of Poincaré. The course will be chiefly descriptive, in showing the principles of the methods, the mathematical difficulties which arise, and the results which have been obtained. Among the subjects treated will be the following: the various forms of the differential equations of dynamics, the existence of integrals, solutions by infinite series, periodic solutions, stability and instability. In neither course will special knowledge of the subject be presupposed.

SCIENTIFIC NOTES AND NEWS.

DR. IRA REMSEN, professor of chemistry in the Johns Hopkins University since its foundation in 1876, has been elected president of the University.

A COMMITTEE, consisting of Professors Ira Remsen, J. S. Ames and W. H. Welch, has been appointed at the Johns Hopkins University to arrange a memorial to the late Professor Henry A. Rowland.

M. LAVERAN, the French army surgeon who discovered the malaria parasite, has been elected a member of the Paris Academy of Sciences in the section of medicine, filling the vacancy caused by the death of M. Potain. In the third ballot M. Laveran received forty, and M. Ch. Richet twenty-six, votes.

AT a recent meeting of the National Geographic Society, the by-laws were so changed as to merge into the single class of 'members' the two classes hitherto designated 'resident members' and 'non resident members,' and also to increase the board of managers from 18 to 24, including six not resident in the District of Columbia. The board has now been completed by the election of the following non-resident members: Professor William M. Davis, Cambridge; Mr. Russell Hinman, New York; Professor Angelo Heilprin, Philadelphia; Dr. Daniel C. Gilman, Baltimore; Professor Rollin D. Salisbury, Chicago, and Professor George Davidson, San Francisco.

DR. G. A. HANSEN, of Bergen, the discoverer of the bacillus of leprosy, will celebrate his sixtieth birthday in July, and it is proposed to present him with an international testimonial made up of small subscriptions. These may be sent to Dr. Sandberg, Bergen.

PROFESSOR EDWARD F. MORLEY, of Adelbert College, has been appointed a delegate from the United States to the International Conference of Weights and Measures, which is to be held in Paris during September.

Dr. Warren P. Lombard, professor of physiology in the University of Michigan, will spend the summer abroad and will attend the International Physiological Congress to be held in Turin in September.

Dr. Franz Boas, professor of anthropology in Columbia University and curator of ethnology in the American Museum of Natural History, has been appointed philologist in the Bureau of American Ethnology. The appointment is an honorary one, and Dr. Boas will direct the work from New York City.

Professor William James offers a course next year at Harvard University on 'The Psychological Elements of Religious Life,' based on the Gifford lectures now being given at Edinburgh.

Dr. T. C. Hopkins, professor of geology at Syracuse University, will work on the geological survey of Indiana during the summer vacation. An attempt will be made to complete the work for a new edition of the geological map of Indiana.

The Carnegie Museum has despatched Mr. W. E. C. Todd, custodian of the collections in ornithology, Dr. D. A. Atkinson and Mr. George Mellor to the Maritime Provinces and Newfoundland to make natural history collections for the museum during the coming summer. Professor J. B. Hatcher is engaged in taking up fossils at Cañon City, Colorado, Mr. O. A. Peterson is continuing the work begun by Professor Hatcher in western Nebraska last year, and the quarry at Camp Carnegie, on Sheep Creek, Wyoming will be worked during the coming summer by a party under Mr. C. W. Gilmore.

Professor C. L. Bristol, of New York University, left New York on June 1 to direct the Biological Station at Bermuda.

The house-boat *Megalops* of the Zoological Survey of Minnesota, under the direction of Professor Nachtrieb, has been hauled ashore near the head of Lake Pepin, a few miles below Red Wing, where it will be used as station headquarters. A gasoline launch has been purchased for this station, and, in line with the plan begun with the rowboat *Zosa*, has been called *Callinectes*. There is also to be constructed a boat specially adapted for dredging and similar work. This boat will be called *Branchippus*. Professor Nachtrieb will send a party of four into the Lake Vermillion region and the N.E. corner of Minnesota. A party of two will conduct special investigations in the Lake of the Woods, and another will carry on work at the Lake Pepin station.

Sir Courtenay Boyle, permanent secretary of the Board of Trade, died in London on May 19. Sir Courtenay had in various official positions contributed much to the applications of science especially as supervised by the government.

Mr. E. W. Parsoné died in London on May 20. He was interested in submarine telegraphy and had done scientific work in connection with the transit of Venus and in other directions.

Mr. Anthony Wilkin died at Cairo on May 17. Although only twenty-four years of age, he had accomplished good work in several scientific expeditions. He was a member of the Cambridge anthropological expedition to Torres Straits, and had carried on archeological work in Egypt with Professor Flinders Petrie.

It is announced that Mr. John D. Rockefeller has given $200,000 for the foundation of an institute for medical research, and it is understood that this fund will be increased as needed. We lack in America an institution corresponding to the Pasteur Institute in Paris or the institution in London recently endowed by Lord Iveagh. It appears that this need will be met by Mr. Rockefeller's gift, though the exact scope of the institution is still under consideration.

It is said that Mr. Alfred Harmsworth has subscribed $50,000 toward an institute in London for the cure of lupus by exposure to light.

The U. S. Civil Service Commission announces that owing to lack of applicants the examination, announced to be held on June 3, for the position of secretary of the National Bureau of Standards, Treasury Department, has been postponed to June 22, and will be held in any city in the United States where postal free delivery has been established. The duties of this position are those of general sec-

retary to a scientific or technical bureau and include the handling of the general correspondence of the Bureau and the editing of bulletins and reports. The occupant of this position will also act as purchasing agent and have charge of the official records, apparatus and equipment, and will be executive officer of the Bureau. The examination will consist of the subjects mentioned below which will be weighted as follows:

1.	Stenography and typewriting	20
2.	Editing and proofreading (practical tests)	10
3.	Education and training	20
4.	General experience in editorial and executive or business capacities	50

The test in typewriting will comprise practical work in tabulating and copying and spacing. Some knowledge of stenography will be required. Applicants for this position should possess a knowledge of elementary physics, chemistry and mathematics, such as prescribed in the general science course of any college or technical school. No person will be examined who has not had a liberal college education or its equivalent. From the eligibles resulting from this examination it is expected that certification will be made to the position of secretary of the National Bureau of Standards, Treasury Department, at a salary of $2,000 per annum.

A CIVIL service examination will be held on July 2d and 3d to fill the position of photographer in the Division of Forestry, U. S. Department of Agriculture, with a salary of $1,200. The examination is on photographic methods, and does not require a knowledge of botany or of forestry.

THE American Academy of Medicine and the American Medical Association are meeting at St. Paul during the present week.

THE American Forestry Association will hold its meeting in affiliation with the American Association at Denver on August 27, 28 and 29.

THE Royal Geographical Society held its anniversary meeting on May 20. Sir Clements Markham, the president, in his address, laid special stress on the British Antarctic Expedition. He said that toward sending a special ship in November, 1902, the sum of £5,500 had been subscribed toward the £15,000 required. The medals were conferred in accordance with the announcements we have already made, Dr. A. Donaldson Smith being present to receive the patron's medal. It was announced that the total number of fellows is 3,997, and the income last year was over £10,000.

THE British Institution of Mechanical Engineers held its annual conversazione on May 17. The annual meeting of the institution will be held at Barrow in Furness during the last week in July.

Owing to an accident connected with the apparatus for adjusting the propeller, the steamship *Discovery*, of the British National Antarctic Expedition has been unable to leave Dundee for London at the time expected.

PROFESSOR H. H. GIGLIOLI, of the Royal Zoological Museum, Florence, writes to *Nature* that on April 13th the second annual meeting of the Zoological Union of Italy concluded its work at Naples. This Union was formed at Pavia last year and in the following September it held its first general meeting at Bologna, which proved to be quite a success as to the work performed and the large attendance. It became evident that the Union, the scope of which is to collect the scattered forces of students of zoology and to prepare the way for the foundation of a zoological journal worthy of Italian science, has responded to a wish generally felt in Italy. The Union now counts amongst its members nearly all the Italian professors of zoology and anatomy and many other students of those sciences. The meeting at Naples was even more numerous than that at Bologna, and many interesting communications were read. Bologna greeted the assembled zoologists with the memories of its old masters—Aldrovandi, Malpighi, Alessandrina and others; at Naples they were *fêted* by that great center of zoological investigations, the Zoological Station, whose steam-launch, which bears the glorious name of *Johannes Müller*, gave the visitors practical examples of pelagic trawling and dredging, as the war steamer *Ercole* bore them to Capri. Rome has been chosen for the third Congress, in 1902, 'when,' remarks Professor Giglioli, 'we shall be proud

and happy to welcome any of our foreign colleagues who should choose to honor us with their presence.'

UNIVERSITY AND EDUCATIONAL NEWS.

HAMLINE UNIVERSITY, at St. Paul, Minn., has received a fund of $100,000 of which $50,000 is from Mr. James J. Hill and $30,000 from Mr. M. G. Norton.

AN Edinburgh correspondent telegraphs to the London *Times* that the details of the scheme already announced of Mr. Andrew Carnegie's great benefaction to his native land appear to have been only partial, and much misconception has been created and adverse criticism made owing to the absence of the full facts. It appears that an understanding was come to by those to whom Mr. Carnegie has already sketched an outline of his scheme that no communication should be made regarding it until the matter had assumed definite shape. This understanding has been violated, and the unfortunate result is that a very misleading, because partial, account of the scope of Mr. Carnegie's munificent gift has been published. Mr. Carnegie has in view a much wider scheme of benefiting Scottish education than that of making education free to Scottish university students. In a few days Scotland will be in possession of the full facts. In the meantime the outline published has given much needless alarm as regards the extra-mural schools. The scheme will amply provide for extra-mural schools, and every boy and every girl who enters a Board school will, if the ability be shown, rise to the highest seat of learning without the payment of a single farthing in fees. Not only will the amplest provision be found to be made to open the gates of knowledge, but also to raise the universities of Scotland to the foremost rank.

IT will be remembered that Yale University has recently abolished required studies in the Sophomore year, and that students may now choose either five or six of twelve subjects that are offered. The elections for next year are as follows: English, 258; history, 216; physics, 194; chemistry, 194; German, 162; French, 155; Latin, 131; mathematics, 112; Greek, 110; mental science, 45; philosophy, 7; analytical geometry, 6.

AT the recent commencement of the Medical Department of the Western University of Pennsylvania, seventy-five diplomas were granted to men who had completed the course of four years in medicine which is required. The Medical Department is engaged in a struggle to resist the encroachment of purely political influence in the appointment of the surgeons and physicians on the staff of the Western Pennsylvania hospital with which the college stands related. The contest is awakening general interest throughout the State.

THE Japanese university for women in the suburbs of Tokio was opened with appropriate ceremonies on April 21.

THE council of the University of Birmingham is prepared to appoint a professor in the proposed faculty of commerce with a salary of £750.

REV. JAMES G. K. MCCLURE, D.D., for the last four years president of Lake Forest University, has handed his resignation to the board of trustees, and Rev. Richard D. Harlan, of Rochester, N. Y., has been elected to the presidency. Dr. McClure only intended to hold the presidency for a short period and had retained the pastorate of the Lake Forest Presbyterian Church.

AT Bryn Mawr College, Dr. Elinor P. Kohler has been promoted to be professor of chemistry and Dr. Allerton Seward Cushman has resigned the associateship in chemistry. Miss Harriet Brooks has been appointed resident fellow in physics and Miss Marie Reimer resident fellow in chemistry.

H. C. HASLAM, M.A., M.B., B.C., of Gonville and Caius College, has been elected to a John Lucas Walker studentship in pathology at Cambridge University. Dr. Sladen, who received permission to leave his work in Cambridge to join his mobilized militia battalion for service in Ashanti, and who has now returned, has been reinstated as a second student.

PROFESSOR ALFRED NEWTON, who holds the chair of zoology and comparative anatomy at Cambridge University, has been excused from delivering lectures during the coming year. His place will be in part supplied by Mr. W. Bateson.

WASHINGTON MEMORIAL INSTITUTION FOR POST-GRADUATE STUDY AND RESEARCH IN WASHINGTON.

DURING the past winter and spring there has been in Washington an active movement having for its object the founding of an institution to facilitate the utilization of the various scientific and other resources of the Government for purposes of research. The aim is cooperation with universities, colleges and individuals in rendering available to men and women the practical post-graduate training which cannot be obtained elsewhere in the United States and which is now available in Washington to a limited degree only.

The movement originated in the Washington Academy of Sciences, which appointed a committee to take charge of the matter. This committee consisted of the president of the Academy, Hon. Charles D. Walcott (chairman); Hon. Carroll D. Wright, Commissioner of Labor; Dr. C. Hart Merriam, of the Department of Agriculture, and Mr. Marcus Baker, of the Geological Survey. Communication was at once established with the board of trustees of the George Washington Memorial Association, who appointed a committee to cooperate with the committee of the Washington Academy, consisting of Mrs. Archibald Hopkins, president of the Association, Mrs. Phoebe A. Hearst and Mrs. L. M. D. Sweat. These

two committees formulated and submitted a plan of agreement, which was approved by the board of managers of the Washington Academy on February 26, 1901, and by the board of trustees of the Memorial Association on March 13, 1901. This plan provided for the founding in the city of Washington of an institution to be known as the *Washington Memorial Institution.*

The objects of the George Washington Memorial Association are, first, as implied in its name, the creation of a memorial to George Washington; and second, as stated in its amended act of incorporation, the increase in the city of Washington of opportunities and facilities for higher education, as recommended by George Washington in his various annual messages to Congress, notably the first—*i. e.*, 'the promotion of science and literature' substantially as set forth in his last will, and by and through such other plans and methods as may be necessary or suitable. The object of the Washington Academy of Sciences, the federated head of the scientific societies of Washington, is the promotion of science, the term 'science' being used in its general sense—'knowledge; comprehension of facts and principles.'

The two organizations agreed, first, that although American universities have so developed since George Washington's time that they fulfill many of the objects of the national university outlined by him as desirable for the youth of the United States, there is still need of an organization in the city of Washington which shall facilitate the utilization of the various scientific and other resources of the Government for purposes of research, thus cooperating with all universities, colleges and individuals in giving men and women the practical post-graduate training which cannot be obtained elsewhere in the United States and which is now available only to a limited degree in the city of Washington; and second, that the best method of securing the objects for which both organizations stand is the establishment, within the District selected by Washington as a site for the permanent seat of government of the United States, of an institution whose object shall be the realization of Washington's repeatedly expressed wish and recommendation that provision be made for the *promotion of science and literature.*

In the further carrying out of cooperation, it was agreed that the George Washington Memorial Association would undertake to secure a suitable site and erect thereon a substantial, dignified building sacred to the memory of George Washington; and that the Washington Academy of Sciences would undertake to provide for the maintenance and conduct of the institution in the interest of science and literature; and that there may be joined with it in this work the National Educational Association, the Association of American Universities, and the Association of Agricultural Colleges and Experiment Stations.

The Washington Academy at once undertook to secure the passage of a law authorizing the utilization of the resources of the Government Departments for post-graduate study and research. Such an act of Congress was approved March 3, 1901, and reads as follows:

> That facilities for study and research in the Government Departments, the Library of Congress, the National Museum, the Zoological Park, the Bureau of Ethnology, the Fish Commission, the Botanic Gardens, and similar institutions hereafter established shall be afforded to scientific investigators and to duly qualified individuals, students, and graduates of institutions of learning in the several States and Territories, as well as in the District of Columbia, under such rules and restrictions as the heads of the Departments and Bureaus mentioned may prescribe.

The plan of organization next agreed upon by the two committees was essentially as follows:

1. *Organization.*—A private foundation independent of Government support or control.

2. *Objects.*—(*a*) To facilitate the use of the scientific and other resources of the Government for research.

(*b*) To cooperate with universities, colleges and individuals in securing to properly qualified persons opportunities for advanced study and research now obtainable only to a limited extent in Washington and not at all elsewhere.

3. *Government.*—The policy, control and management to vest in a board of fifteen trustees, and in addition there shall be an *advisory committee* composed chiefly of the heads of Executive Departments, Bureaus, etc.

The two committees drew up articles of incorporation, which were filed May 20, 1901.

On May 27, 1901, the incorporators met and elected the following board of trustees:

1. Dr. Edwin A. Alderman, President, Tulane University.

2. Prof. A. Graham Bell, Regent, Smithsonian Institution.

3. Dr. Nicholas Murray Butler, Professor of Philosophy and Education, Columbia University.

4. Dr. C. W. Dabney, President, University of Tennessee.

5. Dr. D. C. Gilman, President, Johns Hopkins University.

6. Dr. A. T. Hadley, President, Yale University.

7. Dr. Wm. R. Harper, President, University of Chicago.

8. Mrs. Phoebe A. Hearst, Regent, University of California.

9. Mrs. Archibald Hopkins, President, George Washington Memorial Association.

10. Dr. C. Hart Merriam, U. S. Department of Agriculture.

11. Dr. Cyrus Northrop, President, University of Minnesota.

12. Dr. H. S. Pritchett, President, Massachusetts Institute of Technology.

13. Dr. George M. Sternberg, Surgeon-General, U. S. A.

14. Hon. Charles D. Walcott, President, Washington Academy of Sciences, and Director, U. S. Geological Survey.

15. Hon. Carroll D. Wright, U. S. Commissioner Labor.

On June 3 the trustees met and elected the following officers:

Dr. D. C. Gilman, President, Johns Hopkins University, Director.

Hon. Charles D. Walcott, Director, U. S. Geological Survey, President Board of Trustees.

Dr. Nicholas Murray Butler, Columbia University, Secretary Board of Trustees.

Mr. C. J. Bell, President, Washington Security and Trust Co., Treasurer.

ADVISORY BOARD.

President of the United States.
Chief Justice of the United States.
Secretary of State.
Secretary of the Treasury.
Secretary of War.
Secretary of the Navy.
Secretary of the Interior.
Secretary of Agriculture.
Postmaster-General.
Attorney-General.
Secretary of the Smithsonian Institution.
Commissioner of Education.
Librarian of Congress.
Commissioner of Labor.
Commissioner of Fish and Fisheries.
President of the Civil Service Commission.
President of the National Academy of Sciences.
President of the National Educational Association.
President of the Association of American Universities.
President of the Association of Agricultural Colleges and Experiment Stations.
Dr. Charles W. Eliot.

TRUSTEES.

1903.	1904.	1905.
A. G. Bell,	E. A. Alderman,	N. M. Butler,
C. W. Dabney,	C. H. Merriam,	A. T. Hadley,
D. C. Gilman,	C. Northrop,	W. R. Harper,
P. A. Hearst,	H. S. Pritchett,	C. E. Hopkins,
C. D. Walcott.	G. M. Sternberg.	C. D. Wright.

The new institution will attain substantially the objects desired by the advocates of a National University, without being subject to the objectionable features of a university sustained by the Government in competition with the existing universities.

The committee of the Association of Agricultural Colleges and Experiment Stations on post-graduate study and research in Washington met and approved of the organization of the Washington Memorial

Institution; and it is understood that the committee of the National Educational Association on the question of establishing a National University in Washington approves the plan and purposes of the Washington Memorial Institution. The Washington Academy of Sciences, having turned over to the new organization the conduct and maintenance of the Washington Memorial Institution, will now cooperate with the George Washington Memorial Association in the erection and maintenance of a memorial building to be dedicated to science, literature and the liberal arts.

ADDRESS OF THE PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION.*

In approaching the discharge of my duties as presiding officer of the fifty-second session of the American Medical Association, I beg to express my appreciation of the generous suffrages by which I have been called to a position of such conspicuous honor. This appreciation becomes all the more pronounced when I reflect upon the magnitude and achievements of this great national body and upon the luster of the distinguished men who have presided over its deliberations. This thought brings me to the first duty of the occasion, and that is officially to bring to your attention the fact that since our last reunion three of my most illustrious predecessors have been called from their worldly activities to the realm of rewards. Alfred Stillé, Lewis A. Sayre and Hunter McGuire, each a former president of the Association, died within a single week. Their lives were known of men, their records are ornaments of our annals, and their achievements are their eulogies. They labored zealously and with beneficent results, not alone in the scientific field, but in behalf of an organized national profession; and to guard zealously the splendid legacy which they, among others, have left us, must be one object of our labors upon this auspicious occasion. The hope is indulged that steps may be taken to procure suitable portraits of these and of other deceased presidents of the Association, to be placed in some safe gallery until such time as the Association may be able to transfer them to its own Temple of Fame. I recommend that suitable formal action be taken on this occasion relative to the life, distinguished services and the death of these lamented confreres.

*Delivered before the Fifty-second Annual Session at Saint Paul, Minn., June 4, 1901.

FOREIGN RELATIONS OF THE AMERICAN MEDICAL ASSOCIATION.

The American Medical Association accredited delegates during the last year to several foreign medical conventions, notably the International Medical Congress at Paris, the Dominion Medical Association of Canada, the Mexican National Association and the Pan-American Medical Congress at Havana. To each of these organizations the American Medical Association sustains relations of peculiar intimacy. As one of the great scientific nations of the earth, the United States is naturally an integral part of the International Medical Congress. This Association, by a resolution presented by your present executive officer, took the initiative in 1891, in organizing the Pan-American Medical Congress. The first reunion of that Congress was held in Washington in 1893, under the presidency of the late lamented Dr. William Pepper. The second was held in the City of Mexico in 1896 under the presidency of Dr. Carmona y Valle, while the third has been held during the last few months in the City of Havana under the distinguished presidency of Dr. Juan Santos Fernandez. This movement has for its object the establishment of closer relations between the medical profession of the different countries of the Western Hemisphere. It has already

borne excellent fruit in the increased patronage of our medical schools from the far south, in the improved status of American medical practitioners in Latin America, in a better understanding of quarantine questions in the different countries, and in the development of a concert in the investigation of the medicinal flora of the Western Hemisphere. Our relations with the medical profession of Canada must be of increasing intimacy, and I indulge the hope that, while maintaining the national limitations of our Association for delegate and legislative purposes, its membership, with the privilege of participating in all scientific matters, may be freely opened to our brethren who live beyond our immediate borders.

FISCAL AFFAIRS AND THE JOURNAL.

It has passed into unwritten law, born of the gradually developing features of our organization, that your president shall restrict his annual address to a discussion of the affairs of the Association and to the great object to which, by the terms of its Constitution, it stands consecrated—'the common interests of the medical profession in every part of the United States.' In compliance with this rule, and realizing that I am leaving scientific questions to be presented by orators appointed for the purpose, I have pleasure in calling your attention to the satisfactory condition of the affairs of the Association, as indicated by the consolidated report of the Treasurer and of the Board of Trustees. From it you will observe that under the judicious management of your Board of Trustees you had a cash balance at the end of the last fiscal year of $31,004.67, being an excess of $3,696.66 over the preceding year. Your plant has been increased in value to the amount of nearly $10,000.00, and the net profits of the *Journal* amounted to nearly $14,000.00. You will be gratified to realize that, in addition, you have safely invested as part of a fund with which to buy a home for the *Journal* and for the Association, the respectable sum of $25,000.00. If, however, you have occasion to feel satisfied with the normal condition of your finances, you must contemplate with pride the rapid increase of your *Journal*, in quality, size, circulation and influence. The average weekly circulation grew, during the last fiscal year, from 13,672 to 17,446, and I have added pleasure in informing you that, since the period covered by the report, the weekly circulation has grown to 22,000 copies. For the accomplishment of these splendid results, I feel that you will join me in hearty acknowledgment, not only of the sagacious management by the Board of Trustees, but the tireless industry and the discreet direction of our accomplished editor, Dr. George H. Simmons.

I feel that it is important, however, to call your attention to the fact that it would have been impossible for your Board of Trustees to have accomplished these results if, through its action, the Association had not become incorporated. Leases were to be executed, purchases were to be made, contracts were to be entered into, money was to be loaned and bonds were to be exacted, to do all of which it was necessary that the Association should become a legally organized corporation. This was affected, *ad interim*, by the action of your Board of Trustees, which procured articles of incorporation under the laws of Illinois, bearing date of April 14, 1897. I am not aware that this fact, attested by the document which I have laid before the Executive Committee, has ever been confirmed by the vote of the Association. I recommend, therefore, that such action be taken at the present session.

If, however, the condition of the Association, and particularly of the *Journal*, is, on the whole, occasion for much satisfaction,

certain facts revealed by the report are food for thought. Thus, the *Journal* has an aggregate circulation two and one-half times greater than the aggregate membership of the Association. It would seem, therefore, that while the profession at large prizes the *Journal*, it places relatively less than half as much value upon membership in the Association. This fact becomes strikingly significant when it is remembered that membership can be acquired by those who are eligible at no additional expense and with but trifling inconvenience. Does the *Journal* fulfill all the wants of the profession arising in connection with the Association? Are there no additional advantages to be derived from membership? Is there a lack of *esprit du corps*—a lack of the sense of unity in the profession? Is the existing basis of our national organization distasteful to the majority of the practitioners? Do our subscribers embrace a considerable number of practitioners, who, under existing rules, cannot become members, and whose influence, therefore, cannot be secured in behalf of the Association? These are questions that I am at liberty to ask, and that you are at liberty to answer.

Another thought suggested by the report relates to the disposition of the accumulating surplus. Shall the present policy for creating a fund for the purchase of property be carried out? Shall a larger proportion of the money be expended in still further exploiting the *Journal?* Shall the members receive a direct advantage from the earnings of the property which they have created, by reducing the annual dues, or shall a certain proportion of our surplus be expended in conducting original scientific investigations on subjects of universal interest to the profession? I cannot resist the temptation in this connection to venture replies to these questions far enough to say that, in my opinion, a reserve should be held in hand large enough to meet any possible contingencies that might occur by fire or other disaster in connection with the *Journal*; that the present generous policy in promoting the welfare of the *Journal* should be continued; that the dues of the Association should not be decreased; and that the question of establishing and defraying the expenses of certain commissions for special scientific investigators should be taken under serious consideration. The question of tuberculosis is not yet a closed chapter. The causation of cancer is yet a sealed mystery. The problems of tenement-house reform are not yet solved. The prevention of various endemic diseases has not yet been made practicable. The systematic investigation of the American medicinal flora, begun under the auspices of this Association more than forty years ago, remains an uncompleted task. These are a few among the many objects of a specific character which demand and should receive the fostering care of the Association.

I feel, however, that at the present moment, and under the existing features of our organization, it would be almost impossible to determine, judiciously, either of these very important questions, and I now bring them before the Association only for the purpose of directing attention to them, with the hope that they may be taken up subsequently, and under more auspicious circumstances.

SCIENTIFIC WORK OF THE ASSOCIATION.

The Association began its career with general meetings, devoted chiefly to questions of medical education and professional conduct and to lengthy reports from various standing committees. In 1860 it divided itself into a few sections, each with a certain autonomy, and each devoted to a particular part of our great scientific work. This change was followed by the establishment of the Judicial Council, by which means controversial questions, many of

them of a personal character, were eliminated from the general meetings. The subsequent creation of the Executive Committee still further relieved the general meetings of annoying details. Thus relieved, both the general meetings and the sections have grown in scientific importance, emphasizing the persistence of our devotion to what must ever be recognized as the essential, fundamental object of our organization—the cultivation of the medical sciences. It must be acknowledged, however, that great as has been the progress in this particular, too much of the time of our general sessions is yet devoted to the consideration of matters which might, with propriety, be relegated for final action to a smaller body. It would redound largely to the interest of our annual session if the general membership could be entertained and instructed at our general meetings by exercises of a more purely scientific character, of such broad nature that they should not be restricted to any of the sections. A reform in this particular will be a long step in the direction of progress. The sections, in consequence of the faithful labors of their officers, offer strikingly attractive programs for the present session. In several of the lists will be found the names of invited guests who, through fortuitous circumstances, are not members of the Association, but who are, nevertheless, active workers in the scientific field, and whose participation in our labors will enrich the value of our proceedings and enhance the felicities of the occasion. I bespeak for them your cordial welcome. While the officers of sections and your president have exercised the prerogative of inviting guests, who come as guests, and not as members of any class, as specified by the Constitution, such invitations have been extended solely with the object of advancing the interests of the Association. I look upon this privilege, which has been exercised by all of my predecessors and by previous officers of sections, as one of extreme importance, and one which should be continued under any plan of reorganization which may be adopted. It is my conviction, however, that the privilege should be hedged about by certain limitations, one of the most important of which should be that an invitation should not be extended a second time to any person residing within the United States whose professional qualifications may entitle him to membership. With reference to the invitation of persons identified with the allied sciences, the matter should be left absolutely to the discretion of the president of the Association and with the officers of sections.

CONGRESSIONAL AND STATE LEGISLATIVE AFFAIRS.

The American Medical Association, during the first fifty years of its existence, exerted relatively little influence upon legislation, either State or national. Since the standing Committee on National Legislation and the National Legislative Council of delegates from the State Societies have been established, and have become cooperative, there is some evidence that the voice of the profession is headed at Washington. The experience of the splendid committee of this Association, acting in concert with the National Legislative Council during the last year, has, however, shown the serious necessity for more thorough organization in protecting the interests of the profession and the interests of society, as represented through the profession. The inefficiency of our present organization for influence upon Congress was shown in the inability of your committee, notwithstanding its strong personnel and the influences at its command, to prevent the degradation of the army medical service. This was accomplished by the passage of a bill under the cham-

pionship of Senator Hawley, by the terms of which the medical corps of the army is subjected to unfair and humiliating discrimination. This law grades the medical department for rank, promotion, and, in consequence, for pay, below every other department and special corps of the army, and, with the exception of second lieutenants, it is graded below the line. In accordance with its provisions, a medical officer, to obtain a colonelcy, must pass through three times as many files as an officer of either the Quartermaster's, the Subsistence or the Pay Departments; more than twice as many as an officer of Engineers or of Ordinance, and nearly twice as many as an officer of the Signal Corps. The effect of this discrimination is not only to lower the rank and pay of medical officers, but must result in lessening the efficiency of the corps by repelling men of spirit and worth.

In every war known to history the deaths from preventable diseases have exceeded those due to battle. At no time has hygienic science been so resourceful as at present in preventing disease. A law which fails to give to armies, either in peace or in war, the fullest protection by the application of the latest scientific developments at the hands of specially trained medical men is unjust to the soldier, to society and to the medical profession. In view of these facts, the army reorganization law of the last Congress was inexplicable and inexcusable. It, however, forces itself upon your consideration from another standpoint. Physicians are citizens of the Republic. As such they are intellectually, socially, politically and officially the equals of any other element of the body politic. There is no station to which they may not attain; there is no distinction of which they may not be the recipients. Their rights are of manhood origin, and their prerogatives are inherent. They are, in very fact, peers of the realm, and the peers of any peers of any realm. When the status of any number of physicians in their representative relationship to society is lowered, the status of the medical profession in general is menaced in corresponding degree. When the Congress, by the enactment of a law, degrades, relatively, the status of an important body of medical men engaged in the public service, it strikes at the status of every physician in the country. It becomes, therefore, the duty of every member of the medical profession, jealous of his rights, his prerogatives and the fair name he may leave his children to resent, as personal between himself and every member of the Congress who voted for this law, the action which cast a stigma upon our profession.

It has been the conviction of many enlightened members of the medical profession that the means employed by the general government for the protection and promotion of the public health are capable of improvement. These duties have devolved upon the Marine Hospital Service, which was originally designed to give succor to unfortunate people, without other domicile, who were employed upon our rivers, lakes and the high seas. With the growth of sanitary science this service, being the only established agency available by the government for this purpose, has been largely diverted from its original object. As a result, under the present wise administration of its Surgeon-General, its representatives are abroad investigating the sanitary condition of foreign cities, its agents are at our ports beating back threatened epidemics, while valuable investigations are being conducted in its laboratories. In the exercise of its quarantine functions, however, it comes in conflict with the police power that is guaranteed by the Constitution to the different States. The friction thus engendered has been especially marked

in the seaboard States. While this is true, the Marine Hospital Service, in scope and design, does not fulfill in highest degree the objects of a central coordinating agency for the protection of the public health. It was thought to create a Department of Public Health, with its executive officer in the cabinet, but this idea yielded to that of a bureau in charge of a large Advisory Council, composed of representatives from various States. Resolutions have been adopted and memorials have been sent to the Congress, committees have been appointed, money has been appropriated by this Association, bills have been introduced, and hearings have been had in committee, with the result that the conditions to-day are precisely the same that they were ten years ago, when the agitation was inaugurated in the session of this Association held at Washington.

Secretary Wilson, of the Department of Agriculture, in his Report for 1899, recommended that the Congress appropriate money to defray the expense of a systematic investigation of the medicinal flora of the United States and of experiments upon the neutralization of medicinal plants indigenous to other countries. This recommendation was based upon the fact that the United States is the only great country which either has not conducted or is not conducting such experiments, and upon the fact that the proposed measure, touching the avenues of industry, manufacture, commerce and the public health, was one of national concern. This measure, however, with its manifest importance, was denied even courteous consideration, while its friends were denied a hearing by the committees of the Congress.

The cause of failure on the part of this Association to procure legislation by the Congress—and, with the exception of preventing the passage of the anti-vivisection bill last year and securing the enactment of the quarantine bill this year, our recent efforts must be recognized as failures—I say the causes of our failure are properly subjects for careful consideration. I have examined the records of the Association from the date of its organization, and have been profoundly impressed with the fact that memorials, resolution, or even more definite propositions addressed to the Congress have, for the most part, represented the views, or rather the impressions, of the individual members proposing them. They have generally been presented in the general meeting and have been endorsed without the deliberation essential for wise action; but a deliberation which is simply impossible in the limited time available in our general meetings. In certain instances memorials to the Congress have been presented at one session of the Association, have been referred to committees and reported back for action, either at a later meeting of the same session or at the succeeding annual session of the Association. But it becomes evident that this course lessens the evil but a trifle, for the reason that the committees to which such matters were referred have been constituted either under the leadership of the member proposing the measure or of members of a standing committee who had no interest in or understanding of the proposed measure. Such memorials, resolutions or propositions, when acted upon affirmatively by the general meeting of the Association, have, possibly, been mailed to some member of Congress or of a Legislature, but were not followed by effective work in the rank and file of the profession or among their patrons. When such bills have been presented to the Congress, and have received a certain amount of support from representatives of this Association, they have, as a rule, attained only that degree of importance that have made them valuable to their ostensible champions, as

something to trade in the game and barter of legislation for something which would please a larger number of constituents and command a larger number of votes. In view of the fact that after all the argument of votes is the only one which appeals effectively to the average Congressman, it behooves this Association, in its efforts to conserve the interests of the profession and of society, to put itself in a position to influence the largest number of votes. Every physician, therefore, should, in a perfectly respectable sense, become an active working politician. This subject, however, is of such breadth and of such depth that it may be well for us to pause at this juncture long enough to consider, from the standpoint of fundamental facts, the relationship of physicians to each other, and of the medical profession in the aggregate as an integral factor in society.

THE PROFESSION, THE ASSOCIATION AND THE COMMONWEALTH.

In approaching a study, however brief, of the relation of the medical profession to the state or, as I prefer to call it, the commonwealth, I feel that I am inviting your attention to an eminently practical theme; one which may enable us to understand the influences by which we have arrived at our present estate, and the means by which we may advance to even greater achievements. As we approach this theme—this eminently practical theme—we discover that the status of the medical profession, like that of every other element of that complex whole which we call society, is a perfectly natural one. Whatever it may be, it has been attained in the process of evolution and has been and is determined by laws as immutable as those which govern the commingling of atoms or the sidereal strides of the planets. It is not the result of conventions or of resolutions or of statutory enactments; but these are to be interpreted rather as indiciæ, for the time being, of the position of the profession in the body politic. They are, indeed, consequences rather than causes, and as such they are subjects for careful inquiry. It is by a study of them that we are enabled in part to determine those laws, those natural laws, our harmony with which is essential not alone for the present usefulness and continued progress of the profession, but for the ability of the medical profession to conserve the welfare and promote the happiness of society at large.

But I have said that the position of the medical profession is a natural one. The truth of this declaration is apparent when we go back to the beginnings of society—when we examine the evidences presented by primitive peoples. We are familiar with the classic example so frequently utilized as a starting point in the discussion of sociologic phenomena—the example of the two aborigines, one of whom makes better arrows, and the other, better mats, than his companion, when, presently, one confines himself to arrows, the other to mats, each trading his own for the other's products. Here is an example of the beginning of what the scientists call 'specialization of function in the social organism.' It is an interesting process, which, based upon varying necessities and diverse aptitudes, results in multiplication of handicraft until somebody is hurt. This is a new necessity, and it is met by a new aptitude, and the possessor of that aptitude—the medicine man, our honored progenitor—steps upon the scene. His companions, appreciating his services, reward him with their arrows and mats; and he, finding the life to his liking, restricts himself to his new-found vocation—and the medical profession is established! As the necessity for his services, whether of charm or incantation, becomes more apparent, the esteem of his fellows becomes more pronounced. As events pro-

gress he is accorded certain rights, given certain prerogatives and hedged about by certain limitations, all calculated to increase his efficiency in promoting the common welfare—and thus is the practice of medicine regulated. He is spared from the battle that he may serve his companions, and he stays away from the chase that he may delve into the great mysteries—and thus is medical education inaugurated. He is the exponent not only of his professional knowledge, but of at least the average intelligence of his people. He is, in short, an integral part of the primitive social fabric. As such he shares the manners, the customs, the aims, the ambitions of his companions; and he, with them, is controlled by the forces which determine the common state and the common destiny. His status is, therefore, determined by the very laws which control the growth and development of society itself. So true is this that, from the dawn of history until the present day, and in every stage of sociologic development, the civilization of a people may be infallibly determined by the intelligence, the efficiency and the influence of its medical profession.

THE MEDICAL PROFESSION AND SOCIETY FIFTY YEARS AGO.

It would not be to our present purpose to follow the evolution of society as exemplified in any of the civilized peoples, or, as the scientists say, 'distinct ethnic entities of the world,' in which the present complexity has been attained by an orderly succession of events. And it would be equally unnecessary to show, what everybody knows, that the medical profession, the heritor, in common with others, of antecedent influences, has been propelled by the same forces and by equally orderly events to precisely the same standard of civilization. The lesson before us is that of the relation of the medical profession to a society, which, but a few decades ago, was the most diverse in origin and the most heterogeneous in constitution known to modern history; but a society, which at the dawn of the twentieth century is one of the largest, richest and most intelligent of the world, a society, well amalgamated, and which, by common consent of even adverse critics, is moving in harmony with the most advanced influences of civilization. I fancy I should suddenly find myself unpopular with the audience, if I were to intimate that you, who comprise it—that you, the representatives of the medical profession—have failed to contribute your full quota to the great progress which that society in general has achieved, or that you do not reflect in intelligence and morality the highest type of civilized man. I hasten to allay your apprehension, for I have no such intention. On the contrary, I ask you to indulge with me in a retrospect of American society during the last half dozen decades that we may the better understand the important part that you, and the profession that you represent, have played in the attainment of present results.

As I have already stated, the middle of the nineteenth century found diverse conditions of society in the United States. The older cities of the seaboard were the centers of an advanced civilization. The remoter counties of the same States, however, were then, in the absence of railroads, the telegraph and modern mail facilities, more remote from the centers of American influence than is St. Paul to-day from St. Petersburg. The great tide of emigration that had already poured and was yet pouring over the mountains and spreading in lonely habitations or widely separated communities over the vast valley of the Mississippi from the lakes to the gulf was busily engaged with the serious problems of existence. The forest was to be felled and the prairie was to be subjugated, habitations were to be

built and crops were to be raised. In the midst of these exactions, institutions of higher learning were established, and to an extent patronized, and some strong men were produced. But it must be recognized as true that society in general had but little time and less money to devote either to schooling or to the amenities of life. The medical profession, under these circumstances, was precisely like the community of which it was a part. There were but few medical colleges, and they, for the most part, were but meagerly equipped. Many doctors became such while going from one town to another. Ignorant inventors of alleged systems of cure hawked their wares in the highways and the byways. Dogmatism that was destructive to intelligence was rampant, while schism was fostered by the baneful commercialism that too generally pervaded the heterogeneous mass of forty thousand people that comprised the medical profession. In eight of the twenty-six then existing States, no laws affecting medical practice had ever been enacted; in eleven, laws previously enacted had been repealed; in three only were there any restrictive laws, and these proved inefficient; while the facts could not be ascertained relative to the remaining four States.

THE ERA OF ATTEMPTED VOLUNTARY REGULATION OF MEDICAL PRACTICE.

To remedy these evils, and actuated by the love of science, the promptings of self-interest, and by devotion to the interests of humanity, representatives of the various State medical societies met in convention over half a century ago and organized the American Medical Association, with the avowed object of having its members represent and take cognizance of 'the common interests of the medical profession in every part of the United States.' It sought to cultivate medical knowledge among its members, to elevate the standard of medical education, to promote the honor and influence and interests of the medical profession and to enlighten the public concerning the relation between the medical profession and society. Emulation and concert of action in the profession and friendly intercourse among those engaged in it were additional aims of the founders of this great body of representative American medical practitioners. A constitution, by-laws and certain rules of conduct were adopted. The constitution provided for a delegate body, delegates being accredited from recognized medical societies, medical schools and eleemosynary institutions. The rules of conduct prescribed in detail the deportment of a physician, the deportment of the patient, interdicted the licensure of sectarian physicians, and proscribed from consultation those whose practice was based upon an exclusive dogma. The influence of the new Association was extended chiefly through the avenues of the various State societies, many of which adopted the rules of conduct that had been prescribed by the newly formed national body as the basis of affiliation. Several of the State societies, notably those of Massachusetts, Rhode Island and Mississippi, finding either that the prescribed rules of conduct were not suitable to their respective local conditions, or feeling that they were sufficiently in touch with the ordinary forces of civilization to require no such formulæ, never adopted the rules of conduct prescribed by the national body. The medical association of Alabama adopted the rules with rather a naïve proviso that somebody be appointed to call attention to such of the special teachings of these rules 'as may seem to require elucidation in view of special circumstances and conditions.' Other State societies adopted more or less modifying resolutions, but the general spirit of ostracism and aloofness was maintained during the succeeding three decades. The

result of this movement was immediately salutary; it developed an *esprit du corps* in the great body of the profession; it gave an authoritative definition to medical education and it created a strong and influential national body within the profession. At the same time, however, it became apparent that the organization did not possess the necessary inherent strength to accomplish its avowed object to regulate the practice of medicine. As time passed schismatic medicine grew apace, its colleges multiplied, its practitioners appeared all over the country, exemplifying that law that always makes the blood of the martyrs the seed of the church. Quackery of the most flagrant character was found everywhere, and society was unprotected from its ravages, while the inability of a voluntary unchartered organization to enact and to execute plenary laws was reduced to a demonstration. The medical profession, as an organized body, discovered that its relation to the commonwealth was, as the result of its own proscriptive policy, scarcely more intimate or more influential than at the beginning of the thirty years hopeless experiment.

THE ERA OF EFFECTIVE LEGISLATIVE CONTROL OF MEDICAL PRACTICE.

The era of effective legislative control of medical practice came as the natural reaction from the demonstrated failure to accomplish the same result through voluntary organization; but it came as the result of the sentiment which had been propagated largely through the influence of this Association. The representatives of progressive medicine, turning from the National Association, invoked the aid of their respective State societies in taking up the question with their respective legislatures. The profession in each State, however, recognizing its own local conditions, proceeded in its own way to attend to its own business. The very earliest attempts to secure State legislation revealed the fact that the so-called irregular practitioners, under the stimulus of ostracism and the fostering care of public sympathy thereby induced, had become so numerous and so influential that, in the majority of States, nothing could be done without their co-operation. It was no longer a theory, but a condition, with which the real reformers were confronted—and they met it. California, in 1876, through its regular medical society, took the initiative. After conferences with the representatives of the sectarian societies, and after securing their co-operation, a law was procured creating a licensing board composed of representatives of both the regular and sectarian schools of practice. Illinois, confronted by precisely the same condition, took precisely the same course. Alabama, always progressive, but the happy possessor of other conditions, was able to place the regulation of medical practice for the time being under the control of its incomparable State medical association. Colorado created a mixed board. New York, confronted by conditions even more complicated than those in other States, took up the same task. The profession of that State, acting through its organized body, containing among its members many of the most honored and illustrious names in American medicine, found it doubly necessary to enter into treaty with the denominational physicians. It realized, however, that the rules of conduct to which it had always conformed contained, among other provisions, one which made it unlawful to '* * * examine or sign diplomas or certificates of proficiency for, or otherwise be especially concerned with the graduation of persons whom they have good reason to believe intend to support and practice any exclusive and irregular system of medicine.'

As the thing expressly interdicted by this

rule was the very thing which it was proposed to do, and which had been done in other States, and which it was very necessary to do in New York, the medical society of that State amended the rules of conduct, so that it or its members might, at discretion, enter into professional relations with any or all persons whom the law of the State at that time recognized to be practitioners of medicine. When this action was brought to the attention of this national body, it resulted, not, as might have been expected, in the amendment or the abrogation of the rule which had grown obsolete in the march of events, but in its tacit reaffirmation and in the opprobrious excommunication, for the time being, of the entire profession of the great Empire State. This action, viewed impartially after the lapse of nearly twenty years, becomes the more extraordinary when it is observed that similar action was never taken with regard to Massachusetts or Rhode Island or Mississippi, the societies of none of which had ever adopted the prescribed rules of conduct; nor with regard to California or Illinois or Colorado, each of which had, by overt act, if not by open declaration, so far as this rule is concerned, taken an equally non-conformist position. It is not surprising that, with such an example before the State societies, the experiment in consistency has not been repeated. But the movement of effective regulative legislation, once inaugurated, happily spread with great rapidity. Mixed boards of licensure are now to be found in the majority of the States of the Union, and in the majority of such boards are to be found members of the American Medical Association engaged in issuing licenses to practitioners of exclusive dogmas, and sitting in consultation with sectarian physicians, not over a dose of medicine, but over the vastly more vital question of the qualifications of those who are to care for the sick of our Republic.

THE MEDICAL PROFESSION AND SOCIETY AT THE BEGINNING OF THE TWENTIETH CENTURY.

The result of the twenty-five years of statutory regulation of medical practice are in striking contrast with the results of the quarter of a century of attempted regulations by methods of proscription. At the conclusion of that humiliating experiment, as at the beginning of it, there was not a single effective medical practice law on the statute books of a single State of the Union. To-day there are forty-eight State or territorial licensing boards, most of them being composed of representatives of both the regular and the sectarian schools of practice. The laws of the different States are of varying efficiency, the one procured by the Medical Society of the State of New York, at the price of yet-maintained excommunication from this body, standing to-day as the model of excellence for the entire country. Under the influence of these laws, instigated by members of the American Medical Association, and which, after all, are but expressions of the sentiments of the medical profession confirmed by society at large, many substantial reforms have been accomplished. The medical schools, which in this country have labored bravely and efficiently under adverse conditions, have been stimulated to increased efficiency. One of the first changes accomplished was the practical standardization of requirements to enter practice; and one of the first features of this standardization was to secure for the student 'the aids actually furnished by anatomy, physiology, pathology and organic chemistry'—the four cardinal studies which, strange-sounding as it seems, it was necessary solemnly and specifically to insist upon a half-century ago. It follows, therefore, that with broadened and increasingly uniform curricula, it cannot be said that schools, even of sectarian an-

tecedents, entirely 'reject the accumulated experience of the profession,' nor can it be said that, in a sectarian sense, they any longer possess an excuse for existence. Their graduates, or such of them as do not base practice on an exclusive dogma, are, in many instances, met in formal consultation by even conservative regular physicians, and, in more than one instance, are made members of medical societies that are in affiliation with the American Medical Association.

The Illinois State Medical Society, which has always been among the foremost in reform movements within the profession, at its recent annual session, unanimously

"*Resolved*, That the school of graduation shall be no bar to membership in the Illinois State Medical Society, providing such physician is recognized by the local societies as qualified and not claiming to practice any exclusive system of medicine."

The Ohio State Medical Society, by precedent, if not by formal action, established the same rule.

We thus see that the proscriptive rule which, during the more than twenty-five years of its dominance, propagated the very evils it was intended to correct, is rapidly expiring by limitation in the face of new conditions that have been induced, in spite of it, by beneficent and catholic legislation. In the State of New York alone the annual registration of sectarian physicians has diminished nearly ninety per cent. under the operation of its present laws. In the State of Ohio many physicans who are graduates of sectarian schools are making application to have their classification on the register changed to 'regular,' while equal reactionary movements are observable in other States. Thus we observe the passing of homeopathy and electicism, just as did the calm scientists of Rome witness the passing of the 'humoralism,' the 'Methodism,' the 'electicism,' and the 'pneumatic school' of that period; and just as passed the 'chemicalism,' the 'iatro-physical school,' the 'iatro-chemical school,' and the 'brunonianism' and the dozen other 'isms' of later epochs, each leaving its little modicum of truth as the memento of its existence. And let us felicitate ourselves that, with the passing of the particular sectarianism of the last century, there is also the passing of its concomitant evils, such as existed in even greater degree in the time of Galen, who 'found the medical profession of his time split up into a number of sects, medical science confounded under a multitude of dogmatic systems,' and, as if relating the effect of the cause, the historian continues, 'the social status and the moral integrity of the physician degraded.' The further results of this new order of things, however, are observable, not alone in the modified curricula of the medical schools, but in the changed organic relations of the institutions themselves. Under the pressure of legal requirements the weight falls with almost fatal force upon the small, private and poorly equipped institutions. These institutions, in the interest of self-preservation and to protect a respectable alumni, are forced either to expand their enterprises or to seek relations with universities which are deeply founded in the community; or else actually to go out of existence. The majority of the schools seek connection with the universities, by which step alone they become logical objects for endowment, and it is to be hoped that this movement will continue until in this great country medical education shall be as firmly established as it is to-day in any of the transatlantic nations.

Another of the new conditions which has developed within the last quarter of a century, as the result of an increasing professional unity, is the efficient sanitary regulations, national, State and municipal, that now afford protection to the people from

diseases that were formerly devastating in their effects. It is not necessary in this audience to mention smallpox, cholera, typhoid fever, diphtheria, anthrax, leprosy and the bubonic plague, each of which has been brought under relatively effective control, but I do feel that it is necessary to emphasize the fact that there are many unsolved problems relating to the prevention of disease that stand as a challenge to the industry, the ingenuity and the courage of the profession. While these various changes have taken place, others of almost equal importance are observable in the relations of physicians to society. While the community, instigated by the medical profession, has given to that profession a legal status, definite and increasingly influential, and has given it certain prerogatives and certain exemptions, it has, likewise, hedged it about with certain limitations and imposed upon it certain liabilities. There are numerous laws, both common and statutory—*lex non scripta* and *lex scripta*—that admonish the physician that his conduct carries with it a liability not defined by self-imposed rules, and the numerous courts of our land proclaim that there are tribunals, 'other than his own conscience, to adjudge penalties for carelessness or neglect' on the part of the physician. So numerous, so unjust and so disastrous are actions before such tribunals that they have caused the development of a new, legitimate and beneficent enterprise in the development of a company to insure physicians against malpractice. It may be true that in certain States and localities these laws are unjust, and that there is a grave error in their administration by judges created under our wretched elective system; but if so, the facts only emphasize anew the necessity for more complete organization of the profession and for the more active exertion of its influence upon elections.

THE REORGANIZATION OF THE ASSOCIATION.

This brings us again to a realization of the fact that the results that can be achieved only by the unification of our national profession can not be attained under the present organization of our Association. The disproportionately rapid growth of the *Journal* as compared with that of the Association can have no other significance. The weakness of the Committee on Legislation, at Washington, was a question neither of personnel nor of industry, but arose purely from the fact that there was no efficient organization in the rank and file of the profession by which speedy and effective influence could be brought to bear upon members and senators. Equal difficulty has been encountered in several States where organization has been similarly defective. The demand for more effective organization of the Association has come from all over the country and resulted in the adoption of a motion, at Atlantic City, authorizing the appointment of a committee of three to report a plan of reorganization at this session. Another motion was adopted authorizing the creation of a supplementary committee of one from each State and territory, entitled a Committee on Organization, which has been filled by appointing for the most part the retiring presidents of State societies for the current year. The committee on reorganization, consisting of Dr. J. N. McCormick, Kentucky, Dr. Geo. H. Simmons, of Illinois, and Dr. P. Maxwell Foshay, of Ohio, has given to the important question entrusted to it a most careful and painstaking consideration. It has laid before you the results of its deliberation. In doing so it has emphasized the principle that this Association has its origin in the organized profession of the respective States. It emphasizes the fact that the delegate body should be so small that it can remain in prolonged session and give to the various subjects under consideration that deliberate

attention which has not been possible under the existing scheme of organization during the last forty years. It recognizes the paramount importance of the scientific feature of our work by relieving the general meetings and the sections alike of the troublesome details that now consume the limited and valuable time of the sessions. It remedies the glaring and serious defects in the present constitution. It prepares the Association, by perfecting the organization, to meet important and pressing questions. These considerations, together with the fact that the existing constitutional provision, relative to delay of action on pending amendments, has been met by the appointment, a year ago, of a committee for the avowed and published purpose of reorganization, and by the action of the committee in laying the results of its work before every member of the Association—I say these considerations and these facts prompt me to advise the adoption of the proposed Constitution and By-Laws in their entirety at the present annual session of the Association.

The Committee on Reorganization, under the restrictions of the resolution creating it, has, very properly, left undisturbed the existing rules of conduct. These, if construed to have a fundamental importance, and if vigorously enforced as they now stand, would disintegrate the Association in a single day. This reason, and others already given, confirm me in the conviction that such rules should be either amended or abrogated, or, if reaffirmed, it should be by general resolution endorsing their underlying principles, but disclaiming the present applicability of their details. There are, however, various views entertained upon this subject, and that the matter may be approached in a spirit of tolerance, that it may be discussed coolly and impartially, that a consensus may be reached, and that harmony may be attained, I recommend that the general questions of the revision of the rules of conduct be referred to a special committee on ethics, consisting of three members, with instructions to report to the legislative body at the next annual session of the Association.

THE NEW SCHOOL OF MEDICINE.

The changes which I have advocated are essential for the attainment of the purposes of the Association and for the fulfillment of the high destiny of our national profession. They are demanded by the changes that have taken place during the last fifty years. The legislative functions have passed from voluntary organizations to the Congress and the Legislatures where they belong; but it still devolves upon the profession in the organized capacity to stimulate, to restrain, or otherwise to control the law-making power. The responsibility of the profession is increased, rather than diminished. Science has come to have a clearer meaning. He who now proclaims a dogma cries alone in the night, while the world sleeps. They who demand a creed may read its varying terms only in the progressive revelation of natural laws. Practice has changed. The depletions, the gross medications, the absurd attenuations, the ridiculous anti-mineralism have given away to a refined pharmacy and to a more rational therapy. Sacrificial surgery has yielded to the spirit of conservatism. Prevention is given precedence over cure. Education implies research and discovery, and all may delve. I proclaim, events proclaim, the existence of a new school of medicine. It is as distinct from the schools of fifty years ago as is the Christian dispensation from its pagan antecedents. It is the product of convergent influences, of diverse antecedent origin. It acknowledges no distinctive title, it heralds no shibboleth. It is a school of human tolerance, of personal independence, of scientific honesty. It is

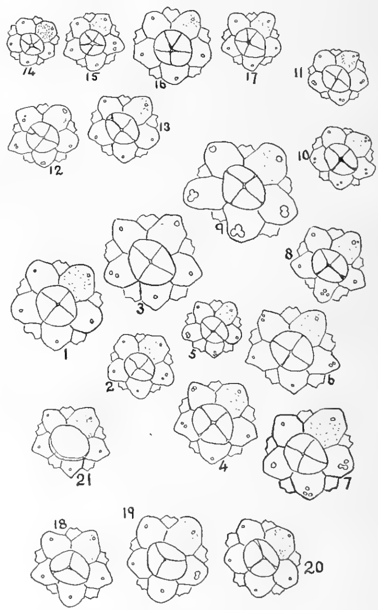
the slave of neither prejudice nor preconception and abandons the accepted truth of yesterday if only it be the demonstrated error of to-day. It places no premium upon personal prerogative, and extends no recognition to individual authority. It makes no proclamation of completeness, no pretension to sufficiency. It recognizes that truth is undergoing progressive revelation, not ending to-day, but continuing through the ages. It yields its plaudits to achievement, and recognizes that he is the greatest among men who reveals the most of truth unto men. It greets as a friend him who thinks, though he think error, for, thinking, he may think truth and thereby add to the common fund. It heeds all things, examines all things, judges all things.

To you, the exponents of this new school, of this new generation, of this new century; to you, representatives of the Democracy of Science; to you, citizens of the Republic of Letters, I extend greetings; and here, in our parliament assembled, here, where our will is supreme, I this day invoke upon our deliberations the spirit of liberty, the spirit of courage, the spirit of progress, the spirit of truth.

CHARLES A. L. REED.

VARIATIONS IN THE APICAL PLATES OF ARBACIA PUNCTULATA FROM WOOD'S HOLL, MASS.

THE object of this note is to call the attention of naturalists to three points of variation in the apical system of the common eastern sea-urchin, *Arbacia punctulata*. The variations may be already known, but I had not noticed them till a year ago, and have never seen any mention of them in print. The observations are based on the study of sixty-three dry specimens sent me for class use from Wood's Holl, Massachusetts, by Mr. F. W. Walmsley. The different plates can be seen very readily if, after removing the spines, the surface be washed and gently brushed with a weak solution of caustic potash and then dried. Great care is necessary in handling the anal plates or they will fall out. The drawings were all made under a camera lucida, magnified four diameters and then reduced one-third. The views are all placed in a similar position, *i. e.*, the anterior radius (as defined by Lang's 'Text-Book of Comparative Anatomy') is with the madreporic plate in the right anterior interradius. The views are arranged so that all those having four anal plates are in the center and those with three or five are below or above. This figure is a view of the



arrangement of apical plates most frequently found, the 'mode,' as it is called by recent writers on variation. It was selected to represent forty-five cases with

respect to the number of anal plates and genital pores. The other figures all represent different cases, none of them exactly duplicated in the whole collection of sixty-five. In No. 1, the mode, we recognize four anal plates an anterior, a posterior, a right and a left. Five genital plates, meeting by a considerable distance and totally excluding the ocular plates from the border of the anal ring. Each genital plate is perforated by a single genital pore. A study of the cases shows that none of these points are constant.

First, as to the number of anal plates, we find variation between three and five with four as the mode. In the case of those with five plates, two have the fifth very small, barely distinct, and the position of each one of the four large ones is similar to that of the mode. It is interesting to find that the fifth in both of the two cases is introduced at the same point, viz., near the left anterior radius. The position of the plates is nearly constant in the specimens with four, though there is a little shifting usually toward the right. Thus in No. 4, the centers of the anterior and posterior plates are strictly in the axial line, but in No. 7 they are not. In the cases with three plates, the anterior seems to have been the one to disappear, the posterior being present and showing the same tendency to shift as just noted. In the cases with five equal plates, Nos. 14–17, the plates show a tendency to be all of them radial in position, *i. e.*, alternate with the genital plates.

The number of pores in the genital plates is also subject to variation, which occurs in a greater percentage of cases than the preceding. In the mode, No. 1, there is a single genital pore in each genital plate. In No. 2, the right posterior genital plate has two pores, one being smaller. In No. 3, there are two large pores well separated. In No. 19, there is in the right posterior genital plate a pore imperfectly divided into two; it is the least deviation from the mode in the collection. No. 5 is an interesting case in which in one plate there are two pores nearly separate and in another three, one distinct and the other two fused. In No. 8, one plate has two pores and another three. Three pores is the maximum number that I have found in one plate. In some cases all three pores are united as in No. 9, or one is distinct and two are united as in 7, or all are distinct as in 7, 8, 10. The maximum number of genital plates in one individual thus furnished with extra pores is four (Nos. 10 and 11 and, possibly, 9); in no case are all the genital plates thus varied. As to frequencies, I notice that it is more often that we find two pores than three. No one of the five genital plates is wholly exempt from this division of the genital pore, but the madreporic plate is least frequently variable. I have found two cases in sixty-five in which it had two pores, and one case with three.

Summarizing the facts as to the number of genital pores, we get the following table, in which the number of pores for each plate is shown; thus the upper and left block of figures shows that the left anterior genital plate has one pore in seven cases, two pores in five cases and three in no case, and so on for the remaining four plates:

	1111111=7		111111111=9	
	22222 =5		22 =2	
	— =0		3 =1	
11111 =5				1111 =4
222222 =6				2222222=7
3 =1				3 =1
		11111=5		
		222 =3		
		3333 =4		

The three posterior plates are thus shown to be more variable than the two anterior plates, and the posterior plates show a stronger tendency to having three pores than any of the others. It is interesting to note that in the subcarboniferous sea-

urchin *Melonites* (Lang, '96, ii, p. 291, Macmillan edition; and Dana, '95, Manual of Geology, p. 641) there are four, or in some genital plates five, pores, instead of one, as regularly in modern genera.

The positions of the ocular plates with reference to the border of the anal ring are subject to variation. The facts in the case are these: In a majority of the 65 *Arbacias* observed the plates are located exactly as shown in Fig. 1, where the madreporic plate meets its two neighbors by a long joint, thus pushing the ocular plate far away from the border of the anal opening, as compared with the left posterior ocular plate, which is only slightly distant from the border. The right posterior ocular and the right anterior are also less separated than the remaining two. This is the mode. The variations from it are on the part of the left posterior ocular chiefly and, in addition, of the right posterior, and less of the left anterior ocular plates. The extreme case of this variation is shown in No. 5, where the left posterior ocular plate participates in the formation of the border of the anal ring, as the right posterior also does, though in a less degree. In No. 21, the same variation is to be seen. Cases in which this form of variation takes place, but in a less extreme degree, are frequently met. No. 17 is such a case; here the left posterior ocular plate barely touches the margin; this is also seen in No. 3. In No. 10 this ocular does not quite reach the margin. The left posterior ocular thus shows a strong tendency to push itself into the anal ring, a tendency shown, too, but in a less degree, by the right posterior ocular and slightly by the left anterior ocular plate. The specimen of *Arbacia*, figured by Brooks in his 'Invertebrate Zoology' ('82, p. 86), which came from Southern waters, shows this same variation as to the left posterior ocular plate. The specimen of *Echinocidaris* (*Arbacia*) *pustulosa*, figured in Lang ('96, Macmillan, Comp. Anat., II., p. 232), shows the two posterior and the left anterior oculars all bordering the ring.

In some sea-urchins (*e. g.*, *Diadema*) all the oculars take a part equally in forming the boundary of the anal ring. In *Salenia*, believed to be a very primitive genus, none of them touch it. In *Strongylocentrotus* there is a condition between these two extremes; in that form the left posterior ocular and the right posterior ocular regularly form a part of the border of the anal ring, and occasionally the left anterior ocular reaches it. In *Arbacia* the corresponding ocular plates vary in the direction of an arrangement which is the mode in *Strongylocentrotus*. A somewhat extended study of the apical systems of *Arbacia* from widely separated localities, together with a similar study of that of some of the other sea-urchins, would probably be of considerable interest to students of variation.

INORGANIC FERMENTS.

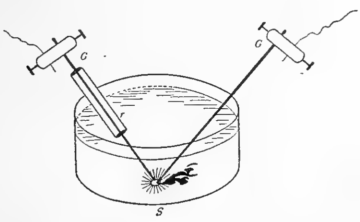
AN article on this subject appeared somewhat more than a year ago in the *Zeitschrift für physikalische Chemie* by Bredig and Müller von Berneck. Quite recently a monograph has been published by Bredig, under this title, containing an account of the experimental work which he has done with others and also an introductory chapter on colloidal solutions, method of preparation, etc.

The monograph begins with a discussion of the general properties of colloidal solutions. Graham found that colloids diffuse very slowly in comparison with crystalloids. Pfeffer showed that colloids exert very small osmotic pressures, and Tammann demonstrated that colloids lower the

vapor-tension of water to only a slight extent.

These facts can be accounted for in two ways, either by assuming that the colloids in solution have very large molecular weights or that colloidal solutions are not true solutions at all, but mechanical mixtures, in which the colloid is in a very fine state of subdivision. The latter view is now generally held for a large number of reasons, and for the metals, at least, seems to be made very probable by the method employed in the preparation of such solutions.

The work of Bredig and his pupils has to do with colloidal solutions of the metals, and the method employed in preparing such solutions is very interesting. Two bars of the metal in question are thrown into the circuit of a suitable electric current, and the lower ends of these poles are immersed in pure water, as shown in the figure. The



ends of the bars of metals, g, g, are brought sufficiently near that an arc is established between them beneath the water. The metal is torn off from the bars in such a fine state of division that it forms in the water a colloidal solution.

In such solutions the metal is so finely divided that it cannot be seen under the most powerful microscope, the solution appearing homogeneous under such conditions.

By the above method colloidal solutions of platinum, palladium, iridium, silver, gold and cadmium were prepared. These solutions had the properties of colloidal solutions in general, and it is quite evident that such solutions are but mechanical mixtures of the very finely divided metals with the solvent, water.

Such solutions of the metals have some quite remarkable properties, and one of these has been studied extensively by Bredig and his pupils.

It was found that colloidal solutions of platinum have the property of decomposing hydrogen dioxide catalytically. A catalyzer is a substance which, in relatively small quantity, can effect a large transformation. The solution of metallic platinum fulfilled this condition, a small amount of the solution decomposing a large amount of hydrogen dioxide. Bredig states that a gram, atomic weight of platinum in 70,000,000 litres of water can appreciably accelerate the velocity of the decomposition of hydrogen dioxide.

Further, in order that a substance may act catalytically, it must apparently not take part in the reaction which it produces, and must remain in an unaltered condition after the reaction is over. The colloidal solution of platinum also fulfilled this condition. Bredig has shown from a study of the velocity of the reaction, by a well-known method, that the decomposition of hydrogen dioxide by the finely divided platinum is a monomolecular reaction; *i. e.*, only one substance—the hydrogen dioxide—takes part in the reaction. The metallic platinum, therefore, does not enter into the reaction at all, but remains unchanged in the solution.

We now come to the most important part of the paper. The author sees an *analogy between the catalytic action of the colloidal platinum and the action of organic ferments.* They point out that recent work has shown that there are many reactions which are effected by both unorganized and organized ferments, and also by the contact

action of many metals and oxides of the metals. A few such reactions will be given:

Alcohol is oxidized to acetic acid by the oxygen of the air, both by the ferment mycoderma aceti, and by finely divided platinum. Calcium formate is decomposed into calcium carbonate, carbon dioxide and hydrogen, not only by certain bacteria, but also by finely divided iridium, rhodium and ruthenium. Dilute solutions of oxalic acid are decomposed by palladium platinum and silver sponge, and also by certain fungi, and the list of such reactions could be very greatly extended. From this it is obvious that analogies between the action of finely divided metals and organic ferments were not entirely wanting when the work under review was begun.

Bredig then attempted to determine how close these apparent analogies really are, by studying very carefully and thoroughly the decomposition of hydrogen dioxide by finely divided platinum.

It has already been pointed out that a very small amount of platinum can decompose a large amount of hydrogen dioxide, just as a small amount of a ferment can effect a large amount of chemical transformation.

It has also been shown that the finely divided platinum does not enter into the reaction, just as a ferment does not enter as such into the reaction.

The presence of electrolytes affects the colloidal condition of the platinum, and, consequently, its activity. They have the same influence on ferments.

But the most striking analogy between the action of these colloidal solutions of the metals and organic ferments is to be found in their conduct in the presence of certain poisonous substances.

Bredig and Reinders showed that hydrogen sulphide in very small quantity, can diminish the catalytic action of the finely divided metal. An akaline solution, containing one gram-atomic weight of sulphur in *ten million litres* of water, can produce an appreciable diminution in the catalytic action of the metal. Schönbein has shown that small quantities of hydrogen sulphide can appreciably diminish the action of organic ferments on hydrogen dioxide.

Bredig and von Berneck have shown that hydrocyanic acid has a remarkable influence on the catalytic action of platinum. Thus, one gram-molecular weight of hydrocyanic acid in *twenty million litres* of water diminishes to one-half the velocity of the decomposition of hydrogen dioxide by colloidal platinum. This again is strikingly analogous to the action of hydrocyanic acid on organic ferments. Schönbein showed that very small quantities of hydrocyanic acid very materially lessen the action of all organic substances which decompose hydrogen dioxide catalytically; and quite recently Buchner has shown that hydrocyanic acid diminishes the action of the 'pressed juice' of yeast on hydrogen dioxide and on other substances.

The 'poisonous' action of a number of other substances, such as bromine, iodine, analine, arsene, arsenious acid, phosphene, phosphorus, carbon monoxide, oxalic acid, mercuric chloride, etc., on the colloidal platinum and on organic ferments was studied, with the result that a general analogy between the two was undoubtedly shown to exist.

The conclusion reached by Bredig as the result of this work can best be stated in his own words:

"All these facts point to an unmistakable analogy between the contact actions in the inorganic world, and the actions of ferments in the organic world. As, in the case of my colloidal catalyzers, we are dealing with reactions in which enormously developed surfaces are involved, so is it probable that the same condition obtains in the actions of ferments, enzymes,

blood corpuscles, and oxidizing and catalyzing organic substances. We see, therefore, that the organism develops its enormous surfaces in the tissues and colloidal ferments not only because it requires osmotic processes, but on account of the very great catalytic activity of such surfaces. If, as Boltzmann says, the war for existence which living matter must wage is a war about free energy, certainly, of all the forms of free energy the *free energy of surface* is the most important for the organism.

"In conclusion, I need scarcely state that I do not maintain that there is any mysterious identity between the metals and the enzymes. But, without exaggerating the overwhelmingly large number of analogies, we are compelled to regard the colloidal solutions of the metals, in many relations at least, *as inorganic models of the organic enzymes.*"

HARRY C. JONES.

SCIENTIFIC BOOKS.

Electric Lighting. By FRANCIS B. CROCKER, E.M., PH.D., Professor of Electrical Engineering in Columbia University, N. Y., and Past President of the American Institute of Electrical Engineers. New York, D. Van Nostrand Co.; London, E. & F. N. Spon.

This book is the second volume of a work, the earlier of which appeared in 1896. The complete work is intended to be a practical treatise on electric lighting for engineers, students and others. The prior volume dealt mainly with the establishment and equipment of electric lighting stations, including locations, buildings, power, dynamos, accumulators, switchboards, measuring instruments, lightning arresters, etc. The present volume, on the other hand, is devoted to that part of an electric light installation which includes the distribution of current and its utilization in various forms of lamps for light. As the author points out in his preface, the space available would not permit the more abstruse consideration of the several divisions of the subject, and this may well be admitted. A glance shows, indeed, that the volume has no waste space; the descriptions are brief, and the data compact and apparently quite accurate. In these respects it is excellent.

The book is eminently practical, but does not neglect the full consideration of principles necessary to a full understanding of the topics treated. It will be valuable as a reference book for engineers on account of the inclusion within its pages of many useful tables and examples.

Beginning with a chapter upon the physical properties of conductors, which includes the application, under limitations and modifications, of the so-called Kelvin's law, and the maximum carrying capacity, there follows a thoroughly adequate treatment of the various systems of electrical distribution in several succeeding chapters. The series systems, parallel systems, three-wire and five-wire distribution, direct current transformer systems and networks of electrical conductors, share the space alloted, in accordance with their importance in actual practice.

Chapters VII. and VIII. contain brief, but very lucid, expositions of the principles of alternating currents and polyphase currents respectively, after which follows a chapter devoted to a similar treatment of that very important adjunct, the alternating current transformer. The two succeeding chapters relate to alternating current systems of distribution and the calculation of such circuits. The matter appears to be well put together, and is amply elucidated by diagrams. The part of the work devoted to the distribution of delivery of energy to the place desired is concluded by a full and judicious consideration of overhead and underground conductors. Here may be found ample details of line construction, conduits, etc., as exemplified in the most recent construction, particularly in America.

The remaining portion of the volume proper is devoted to the utilization of the energy for lighting, as in arc lamps and in incandescent lamps, in addition to the accompanying interior wiring, and electric meters. The work concludes with appendices, one of which contains the National Electric Code of the Board of Fire Underwriters, and the report of the Committee

of the American Institute of Electrical Engineers on Standardization. The inclusion of this matter is certainly to be commended, and it increases the value of an already valuable technical treatise.

The chapters on electric arcs and arc lamps will be found to embody the later knowledge and developments, such as have only appeared in separate scientific papers or technical publications. Likewise the section on incandescent lamps is fully modern, as could not fail to be the case, as it has been revised by Mr. John W. Howell, whose authority on the subject is beyond dispute.

The work has so much calling for commendation that it would be surprising if a few slips of the pen did not occur. In dealing with such a large amount of technical matter it is difficult to avoid occasional use of phrases a little crude, but if the meaning is clear no harm is done. Exception may be taken to some things stated as facts, which are still undetermined. For example, on page 322, 'the retention of the heat by the bulb' in inclosed arcs is involved to save this type of arc from inefficiency as compared with the open air arc. Also, just following, it is stated that "Evidently a large bulb will be less efficient than a small one and will *also tend to produce a carbon deposit by chilling the vapor on its cooler surface.*" This involves the inadmissible idea that carbon vapor can *exist* away from the arc flame as such, when in fact carbon would be condensed as soot unless burned before leaving the arc flame. If we deprive the inclosed arc too completely of air a small bulb is more rapidly rendered opaque by soot deposits than a large one.

There is a manifest inconsistency seen in comparing paragraph headed 'Current and Voltage,' page 312, with paragraph 'Efficiency,' page 325. Here the inclosed arc is made to appear by tests accredited to Freedman, at least as efficient as the open air arc, in contradiction to the opening sentence under 'Efficiency,' page 322. The fact is that there are other measurements of arcs extant which are far less favorable to the inclosed arc than those used in the book, and the former are probably nearer the truth.

The author has, in several instances, wisely availed himself of publications issued by the manufacturing companies, and many chapters are followed by references to papers and publications which have been consulted, though the chapters dealing with arcs and arc lamps are an exception. This brings to notice what may appear to some as a defect of the work. It is evidently not intended to be historical, yet names and sometimes dates are used, but there appears throughout no consistent policy in that respect. Names occur sometimes in connection with relatively unimportant suggestions, though in other more important connections they are omitted. Credit is even given, sometimes, to the same worker for certain things and withheld at other times, though the objects in the latter case may be of the greater practical value. Few instances appear to exist in which the credit given is misplaced, as with the transformer figured on page 174. Notwithstanding this, the work gives ample evidence of the ability and industry of its author, and must be welcomed as a valuable addition to electrical literature. It is well printed, admirably illustrated, and the figures are clear and well chosen.

ELIHU THOMSON.

Chemical Technology. Edited by E. CHARLES GROVES and WILLIAM THORP. Vol. III. *Gas Lighting*, by CHARLES HUNT. Published by P. Blakiston's Son & Co., Philadelphia. Large 8vo. Pp. 312. Price $3.50.

This work deals very fully and satisfactorily with the manufacture of gas for the purposes of illumination, the various forms of retorts, settings, condensers, scrubbers, governors, etc., being carefully and minutely considered. The methods of chemically testing and measuring the gas are clearly and concisely explained.

More than one-eighth of the book is devoted to oil and water gas, nearly every important process for their manufacture being detailed. The treatise closes with an excellent chapter on burners, all the principal ones being described; no mention is made of the 'bec Feron,' a French mantle burner of high power using a mixture of gas and air under pressure.

In view of the extended use of inclined retorts, the reviewer considers the treatment of this subject too brief; this remark applies also

with even more force to the topic of acetylene. Strangely enough, no directions are given for the photometric testing of gas (save for street testing), so that for this important measurement recourse must be had to another book. From a typographical standpoint too, the book leaves something to be desired ; several of the cuts, for example, Figs. 43, 204, 207 and 211, are not clear.

The work in the main is excellent and should be in the library of every one interested in the subject of gas.

AUGUSTUS H. GILL.

Lehrbuch der vergleichenden Anatomie der Wirbellosen Thiere. Von ARNOLD LANG. 2te aufl. 1ste lief. bearbeitet von DR. KARL HESCHELER. Jena, Gustav Fischer. 1900. Pp. viii + 509, mit 410 abb.

In this volume is included the molluscan part of Lang's well-known and useful work, enlarged, revised and additionally illustrated.

The difference between the original or the excellent translation of Bernard (Macmillan, 1896, pp. 283, ills. 222) is not so great as the figures seem to imply, and is largely accounted for by the increased size of the type and the addition of 188 new cuts. A brief summary of the chief additions may be useful.

In the 'systematic review' we find the sequence of the orders changed in the Gastropods, and, in the Pelecypods, a number of suborders introduced ; while the unnatural and illogical orders of the Pelseneerian classification, and his jumbled-up collocations of families under them, are still retained, though a synopsis of later views is included. In the review of 'superficial organization' the Amphineura are recognized as a class and a short chapter on the Cephalopod shell is added.

Under 'pallial complex,' reference is made to the discovery of gills in certain fresh-water pulmonates which is further enlarged on under 'Respiration,' and the characters of the Janellidæ, not referred to in the first edition, are discussed. The chapter on respiration is enlarged and a general summary appended.

A few remarks on *Spirula* are added under 'Musculature,' and under 'Asymmetry' new information is added and the author's theory discussed in the light thus thrown on the subject, with a reference to the bibliography for the opinions of others on this topic.

The phosphorescent organs form the subject of an appendix to the 'sensory organs,' and, under 'alimentary canal,' additional information is given on the proboscis in *Conus*, *Terebra*, *Cassis*, *Dolium* and *Pyrula*.

The general discussion on the intestinal region, stomach and hepatic glands is somewhat enlarged. The asserted absence of endothelial investment in the alimentary canal and digestive glands is alluded to, and the general discussion of the nephridia has been enlarged.

Under 'Reproductive Organs' we find additional matter in the general discussion, and also relating to the Ascoglossa and Holohepatica, among the Nudibranchs, and the Stylommatophora among the pulmonates.

The chapter on the 'Parasitic Gastropods' has been expanded and notes on *Thyca* and *Mucronalia* added.

Under 'Ontogeny' we note additions in connection with *Ischnochiton*, *Vivipara*, *Limax*, *Dreissensia*, *Yoldia* and *Loligo*, and the entire portion relating to Cephalopoda seems to have undergone amplification and revision. Much-improved indices and enlarged bibliography are subjects for gratitude.

The summary of facts in relation to molluscan anatomy included in this work is rich, and may be consulted with profit by those interested, though entering less into detail than the work of Simroth in the new edition of Bronn's 'Thierreichs' which is not yet complete.

Whether the training which most anatomists get is of a kind which impairs their faculties for generalization is a question difficult to answer ; but it is certain that most of the younger contributors to anatomy in mollusks have not much advanced the science by their simultaneous hypotheses bearing on classification. The cause seems to be that they do not realize the vastness of the untrodden field in the molluscan subkingdom and generalize on too limited data. Furthermore, other animals are often so much easier to handle and require so much less labor in investigation to afford tangible results, that it is not remarkable that most instructors turn to animals of smaller size and simpler organi-

zation to obtain subjects for their pupils; and consequently the neglect of the mollusca continues.

The work of Lang might have advantageously been supplemented by a chapter calling attention to the gaps in our knowledge and emphasizing the need of research and the rewards which will undoubtedly fall to the lot of him who decides to investigate patiently in a field where not one in a thousand species is anatomically known, and where a careful embryological study, as of the development of the gills in Pelecypods, will produce the most far-reaching results, if carried out with thoroughness.

When this student appears, he will find in the work of Lang a storehouse of facts and a record of hypotheses which cannot fail to be of the greatest service in his studies.

W. H. Dall.

Clays of New York, their Properties and Uses. By Heinrich Ries. Bulletin of the N. Y. State Museum, No. 35. Vol. 7. 1900. Pp. 450. Plates, 140.

Somewhat over ten years ago, the author of the work before us took up the study of the clays of the Hudson River region and the industries based upon them. The venture had all the charm of novelty, because up to that time it had not occurred to anyone to investigate these humble resources, which had apparently impressed all observers as possessing little of interest or of importance. And yet the investigation proved that the clays of the state were the raw material of the most important of all its mineral industries, and they had evidently been passed by, because of their ordinary and simple nature, because they did not appeal to the imagination. The experience is not unique, as will be seen from the following incident. While the writer was recently discussing the subject with a Russian friend, the latter remarked that he had discovered on the steppes, extensive deposits of china-clay, which, when worked up and sold, would bring $150.00 per ton. He had great difficulty in arousing interest, and yet had he found in any such quantity, gold ore worth $5.00 or $10.00 per ton the greatest excitement would have immediately broken out.

Ten years ago in America, scientific interest in clays was chiefly limited to those which supplied refractory materials. Our literature was small. The New Jersey Geological Survey prepared a valuable report in 1878, and in the later eighties the Geological Survey of Ohio published an important contribution, both reports being issued by States where the fire-brick industry was and is important, but except for these two contributions almost no attention had been elsewhere paid to clays by official scientific bodies. Conditions have greatly changed since then; the vitrified brick industry has sprung up; shales, once the most despised and neglected of rocks, are now utilized in enormous quantity; clays are purified and washed, and the ceramic arts have made great strides. It is but just to Dr. Ries to say that his writings have contributed in no small degree to the result and have brought within the reach of workers and readers alike, the possibilities of this invaluable raw material.

The present work is his most extensive contribution. To estimate it properly, it must be appreciated that it is intended as much for the practical workers as for the libraries and laboratories of institutions of learning. The balancing of theoretical investigations with descriptive matter has therefore been necessarily considered with care by the author, but it has been performed with discretion and in a way to attain the most useful result. The scientific reader, however, will be glad to know that all the author's results in the investigation of the physical properties of clays have not yet been published and that further contributions may be expected.

The work opens with the generalities of clays; their origin; mineralogy; properties; analysis; classification; geologic distribution in New York and in the United States.

The methods of digging clay and the geologic features of the deposits are then described, after which the brickmaking industry receives detailed description. This is followed by terra cotta, roofing tile, sewer pipe, hollow brick, etc.; floor tile, decorative tile, fire clays and pottery; each of which topics is treated at length. The properties and uses of shales are next taken up and with them feldspar is placed

as a sub-topic, somewhat illogically as it would seem.

Many minor uses of clays, as in cements, paints, paper-filling, road-materials, etc., are next reviewed, and then the various tests of different clay products are described as an aid to the practical worker. An extensive compilation of clay analyses, an excellent bibliography and a directory of clay workers in New York State conclude the bulletin.

The book is encyclopedic in treatment and will prove a valuable work of reference not only within but without the State.

J. F. KEMP.

COLUMBIA UNIVERSITY.

SCIENTIFIC JOURNALS AND ARTICLES.

THE first number has been issued of *Kirchhoff's Technische Blätter*, a weekly periodical not intended for popular reading, but having for its purpose the accurate rendition of scientific and technical matter. The idea of its editor and publisher is to supply these 'leaves' not only to individual subscribers but, and principally, to the subscribers to the newspapers, as supplements to regular issues. By this plan the newspaper is able to offer its readers popular but scientifically correct accounts of current progress and advances in technical departments, written by scientific men of recognized standing and often without appreciable additional expense. The list of already promised contributions includes articles by a large proportion of the leading scientific men of Germany and many in other countries. The first number contains, for example, articles on the Berlin-Cologne electric railway by Arthur Kirchhoff, on metallurgical work by Dr. Wedding, on his flying machine by Hofmann, on the steam-turbine by Professor Kubler, and a variety of other interesting matter, well condensed as also well selected. The enterprise is a novel one and deserves success. One would think that such a plan would prove practicable in the United States, more than in Europe; since many of our newspapers, notably the New York *Sun* and the *Times*, have long owed something of their reputation to their interest in, and accuracy of statememt regarding, scientific and technical matters. Like the new German periodical, they have secured their information from experts familiar with the subjects discussed and competent not only to present a clear and concise account of a scientific or technical advance, but also to advise regarding the importance of the matter and the advisability of giving it space. Fads and frauds and follies are thus avoided.

R. H. T.

The American Naturalist for May begins with an account of 'Two New Myrmecophilous Genera of Aberrant Phoridæ from Texas,' by Charles T. Bruce, these being wingless Diptera of a family before unknown in America. L. B. Walton discusses 'The Metathoracic Pterygoda of the Hexapoda and their Relation to the Wings,' concluding that the typical thoracic segment possesses the components of both pterygodum and wing, and Vernon L. Kellogg considers 'Phagocytosis in the Postembryonic Development of the Diptera.' H. S. Jennings has a paper 'On the Significance of the Spiral Swimming of Organisms,' considering that by means of this many creatures, even those not symmetrical, are enabled to pursue what in the main is a straight course. The 'Synopses of North American Invertebrates' contains the second part of the Hydromedusæ, by Chas. W. Hargitt. The 'Reviews of Recent Literature' are unusually numerous, occupying nearly 40 pages.

The Plant World for May contains the final part of 'Hints on Herborizing,' by A. H. Curtiss; 'The Asparagus Rust,' by Byron D. Halstead, and many briefer articles, notes on current literature and reviews. In the 'Families of Flowering Plants,' Charles L. Pollard treats a number of families of the Rosales.

The Journal of the Boston Society of Medical Sciences for April 23, contains 'A Contribution to the Normal Histology and Pathology of the Hemolymph Glands,' by A. S. Warthin; a second paper on 'The Relation between Physique and Mental Work,' by Henry G. Beyer, in which additional evidence is adduced to show that, as a rule, physical and mental ability go hand in hand, and an article on 'Typhoid

Choletcytitis with Observations on Gall Stone Formation,' by J. H. Pratt.

The Popular Science Monthly for June opens with a timely article on 'Our Forest Reservations,' by J. W. Toumey, in which the subject is discussed from various points of view. David Starr Jordan presents the second instalment of 'The Blood of the Nation,' showing how the slaughter of the flower of the nation in war contributes to the survival of the unfit, and Robert H. Thurston gives the concluding portion of his paper on 'Progress and Tendency of Mechanical Engineering in the Nineteenth Century.' Jas. Lewis Howe discusses 'The Periodic Law,' and Henry A. Rowland's 'A Plea for Pure Science,' is republished as a tribute to his memory, while Gary N. Calkins treats at some length of 'The Malaria Germ and Allied Forms of Sporozoa.' Francis H. Herrick has a well-illustrated article on 'The Wild Bird at Arm's Length; A New Method of Bird Study,' this consisting in removing the branch to which a nest with young birds is attached to some accessible spot near by a green tent, from which the birds are observed and photographed at a short distance. The final article is the sixth portion of 'A Study of British Genius,' by Havelock Ellis, this being devoted to marriage and family.

Bird-Lore for May–June opens with an article by John Burroughs on 'A Bewildered Phœbe,' followed by 'Bird-Nesting with Burroughs,' by Frank M. Chapman, well illustrated from photographs. Annie Trumbull Slosson contributes 'A Sudden Friendship,' showing how tame wild birds may suddenly become. The fourth series of 'Birds and Seasons' treats of the forms to be observed from Boston to Stockton, Cal., incidentally including the statement that Dr. W. L. Ralph is to continue the 'Life Histories of North American Birds' which was begun by the late Major Bendire. Among the various articles in the different 'departments' is one of special interest entitled 'A Connecticut Game Peserve,' by Willard G. Van Name, which hints at a successful method of increasing the birds by making a reservation where they are protected at all seasons and fed during winter and whence they spread into adjacent territory.

SOCIETIES AND ACADEMIES.

THE NEW YORK SECTION OF THE AMERICAN CHEMICAL SOCIETY.

The regular meeting of the New York Section of the American Chemical Society was held May 10th, at the Chemists' Club, 108 West 55th Street, Dr. C. A. Doremus presiding.

The following papers were read:

'The Quantitative Determination of Cadmium,' by E. H. Miller and R. W. Page.

'On the Relation of Chemical Constitution to the Physiological Action of Certain Modern Anæsthetics,' by W. E. Dreyfus.

'Alloys of Titanium and Titanium Steel' by A. J. Rossi.

(*a*) 'Chemical Nature of the Enzymes,' (*b*) 'Note on Nucleic Acid,' by P. A. Levene, read by Dr. S. Bookman.

'Analysis of Garden Sage, with Notes on the Determination of Essential Oils,' by L. L. Watters.

Each of the papers received some discussion.

A communication was read from the chairman of the New York Section of Chemical Industry, relative to the appointment by that body of a committee to secure 'uniformity in technical analysis'; and stating that a subcommittee had been appointed to investigate the analysis of Portland Cement. Also that work on this line had commenced and that members of the New York Section of the American Chemical Society were invited to cooperate.

It was moved and seconded that the matters be brought before the council with the recommendation that a committee be appointed to cooperate with the committee of the Society of Chemical Industry.

It was also voted that the chairman of the New York Section be returned as a local delegate to the council of the Society, provided he be not already a member of the council as delegate-at-large.

Durand Woodman,
Secretary.

DISCUSSION AND CORRESPONDENCE.

THE MOTION OF A TOP.

The elementary explanations of this motion generally labor under the difficulty which attended the explanations of the late Professor Pliny Earle Chase, that is, they need an ex-

planation. Such a result might be expected when we consider the difficulties of the question. The student should understand that he must face the difficulties, and that he can not overcome them without serious study. A good analytical exposition will be found in the 'Mecanique' of Poisson. But the most satisfactory investigation of such motions is given by Poinsot, by means of the theory of couples. An interesting example is that of the precession and nutation of the equinoxes. If we form the couples around the earth's axis of rotation, around the line of equinoxes, and around the line in the earth's equator, directed toward the solstice; we find that the couple around the axis of rotation is zero; the couple around the line of equinoxes gives the precession; and the couple around the other axis produces the nutation. By substituting the force arising from the action of the sun, expanding by the binomial theorem, and retaining only the first terms, the solar precession comes out $15''.6$ in a year. The calculation for the moon is not so easy because the moon does not move in the ecliptic; but, since we can compound couples like forces, there is no difficulty except the length of the work. The precession produced by the moon is $34''.8$: hence the sum, or the luni-solar precession is $50''.4$. Observation gives $50''.35$; this simple method therefore gives a good approximation to the true value.

The mass of the earth disappears when we compound the couples, and the precession would be the same if the earth were a shell of the same figure. The precession has a secular character, since when we integrate we find a constant factor multiplied by the time. Again, since the precession is negative, the dynamical result shows that the earth is flattened at the poles, and not elongated as Cassini thought.

The nutation can be found in the same way from the couple around the third axis, but it has a periodical character, and changes sign with the longitude of the moon. The computed value agrees well with observation.

Poinsot's work is a remarkable example of what can be done by the careful study and examination of the geometrical conditions of a question.

A. HALL.

CAMBRIDGE, May 31, 1901.

MODULUS OF CONSTANT CROSS SECTION.

TO THE EDITOR OF SCIENCE: In the last number of SCIENCE there appears a short article with the above heading, in which the author says he can find no mention anywhere of a modulus of constant cross section. The modulus here referred to will be found in a number of treatises on elasticity, among others the article 'Elasticity,' in 'Encyclopædia Brittanica,' Vol. VII., p. 807, and Rankine's 'Applied Mechanics,' p. 279, where a numerical value is quoted for brass. If k be the volume modulus and n the rigidity modulus the modulus for constant cross section is $k + \frac{4}{3} n$.

The author may profit by the study of the thermodynamics of elasticity as given in the 'Britannica' article.

THOMAS GRAY.

ROSE POLYTECHNIC INSTITUTE,
May 27, 1901.

NOTE ON THE GENUS HOLLANDIA OF KARSCH.

IN reading over the sixth volume of the Cambridge Natural History (Insects) by Dr. David Sharp, p. 396, the writer notes the following statement: "The tropical African Arbelidæ are considered by Karsch to be a distinct family, Hollandiidæ."

Upon looking up the matter I discover that Dr. F. Karsch, in the twenty-second volume of the 'Entomologische Nachrichten' (1896), p. 137, erected a genus in honor of Dr. W. J. Holland, of Pittsburgh, calling it *Hollandia*, and selecting as the type of the genus the species named and described by him as *Hollandia togoica*. He further made this genus the type of a new family, the *Hollandiidæ*, to which he referred the genera *Hollandia* Karsch, *Arbelodes* Karsch, *Lebedodes* Holland, and *Metarbela* Holland.

Dr. Karsch unfortunately overlooked the fact that in the *Annals and Magazine of Natural History* for October, 1892 (p. 295), Dr. Arthur G. Butler had already described a genus of African moths, naming it *Hollandia*, in honor of the same gentleman, whom Dr. Karsch states it to be his wish to recognize. Dr. Karsch's name, therefore, falls into the list of synonyms together with the family name, which he has proposed.

The writer suggests for the genus described

by Karsch the name *Hollandella*. I am, like Dr. Sharp, unable to recognize characters of family value, and the distinction between the group, typified by the genus in question, and the generally recognized constituents of the family Arbelidæ appears to me to be of not more than subfamily importance. From this standpoint the nomenclature would be as follows: Family Arbelidæ, subfamily *Hollandellinæ*, genus *Hollandella*, etc.

I imagine that the change which I propose will not be displeasing either to Dr. Karsch, the learned custodian of the Royal Museum of Natural History in Berlin, or to my friend the Director of the Carnegie Museum.

THEO. GILL.

WASHINGTON, May. 1901.

CURRENT NOTES ON PHYSIOGRAPHY.

U. S. GEOLOGIC FOLIOS.

THE folios of the Geologic Atlas of the United States continue to furnish an unrivaled source of physiographic as well as of geologic information. Among the more recent, the following may be noted: The Monterey folio (Va., W. Va., Darton) exhibits the crowded Appalachians bordering the Allegheny plateau, a district of strongly corrugated strata now reduced to ridges and valleys of anticlinal, synclinal and monoclinal structure. Bristol (Va., Tenn., Campbell) includes a monoclinal belt with many overthrust faults, characteristic of the Appalachians in Tennessee; the mountains here are nearly rectilinear, in contrast to the sharp-turning zigzags further northeast. Between the mountains is an open country with many low ridges, once a lowland, but now dissected after a gently slanting uplift. Standingstone (Tenn., Campbell) presents a portion of the Cumberland plateau, with its ragged west ern escarpment descending to the 'highlands,' themselves dissected by streams that go to the lowlands next west. Uvalde (Tex., Vaughan) contains a part of the Rio Grande plain bordering the Edwards plateau whose dissected es carpment appears on the north. The plateau has yielded sand and silt with which the broad valleys of the plain are washed; here the streams frequently disappear and reappear, the Nueces river being an unusually large example of this kind. Elmoro (Col., Hills) shows the broad Plains that front the Rocky mountains near Trinidad to be surfaces of denudation, remnants of the removed strata being preserved under the lavas of Raton mesa; the Plains are now somewhat trenched by the streams. Fort Benton (Mont., Weed) gives another illustration of the great denudation by which the Plains have been formed, as testified to by the isolation of the Highwood mountains, an embossed body of dissected lavas and dikes; the larger river valleys of to-day are here sharply sunk beneath the Plains. Little Belt (Mont., Weed) affords an excellent illustration of the topographic consequences of the Neocene warping, for the modern deposits of Smith river basin (described as lacustrine, although consisting of irregularly bedded sands and loose conglomerates) overlap unconformably upon both the denuded central and marginal rocks of the greater Laramie deformation. Like the Highwood mountains, south of Fort Benton, the Crazy mountains, a network of dikes, here testify to the great erosion of the Plains that they overlook. Absaroka (Wyo., Hague) is characterized by the superb dissection of a high plateau of lavas and volcanic breccias; the whole region has been glaciated, and some of the valleys heading in great cirques seem to show glacial scouring in their smooth-sided, trough-like forms. Tacoma (Wash., Willis and Smith) includes examples of channels of ancient glaciers between uplands largely composed of drift; the channels now being invaded by the sea from without and by alluvium from within; the sounds are thus explained by retreat of the ice and not by depression of the land. Mother-Lode (Cal., Ransome) exhibits parts of the uplifted and dissected peneplain of the Sierra Nevada; it was strewn with gravels and flooded with lavas and volcanic conglomerates before uplift; it is now trenched by canyon-valleys. A few eminences surmount the uplands; several lava-capped table mountains standing up with long even-crested tops between the valleys.

RIVERS OF EAST YORKSHIRE.

THE subject of the Sedgwick essay announced by Cambridge University for 1900 was on the dependence of water-courses upon geological

structure, with the stipulation that the area studied should be British. The prize for the best essay was awarded to F. R. Cowper Reed, of Trinity College, who wrote on 'The Geological History of the Rivers of East Yorkshire' (London, Clay and Sons, 1901, 103 pp., map, 8 cuts). Thirty pages are given to a geological history of the region. River development began with the post-Cretaceous uplift and continued through a first cycle with important adjustments till an extensive peneplain had been formed. Near the close of Oligocene time came another uplift, affecting the British Isles and Western Europe. The rivers of the peneplain were thus revived and set to work sculpturing the existent topography; and at this time it is believed that a flat anticline was formed along the axis of the moorland north of the vale of Pickering, producing important changes in certain stream courses. A depression of moderate amount occurred near the end of the Pliocene; the area of greatest sinking then came to be occupied by the North sea, whose extent has since been increased by wave work along the shore. Then came the glacial period and its changes of level, when many valleys were clogged with till and many streams were reversed by ice blockades. Since the ice retreated, a small uplift and a small depression have occurred. The development of river courses is followed through these various land movements, special attention being given to the changes caused by the growth of subsequent branches along belts of weak strata, and by till and ice barriers. The essay is easily the most detailed and successful study of the rivers of northern England that has yet appeared.

THE VOGTLAND.

A DISTRICT of uplands and valleys, drained chiefly by the Elster, roughly located as in the southwest corner of Saxony, and known as the Vogtland, has been described by Wohlrab ('Das Vogtland als geographisches Individuum,' Forsch. deut. Landes u. Volkeskunde, XII., 1899, 101–185, map and plates). The essay is interesting as a partial recognition of the necessity of treating geographical forms with respect to their origin, yet it is hampered by the retention of certain traditional empirical methods and by the incomplete adoption of more modern rational methods. The gently undulating uplands of schists, surmounted by low ridges and knobs of harder rocks, are properly presented as a worn-down old-mountain surface; but the descriptions of its landscapes thus considered are all quoted, as if the author wished to leave to others the responsibility of so venturesome an explanation. No explicit mention is made of the slanting uplift of the region, whereby its streams were enabled to incise their modern valleys. Indeed, the occurrence of bold and rocky valley sides beneath the milder scenery of the rolling uplands is presented as if it were somewhat out of the order of nature, worthy of being looked on as a curiosity, instead of the well-understood and commonplace accompaniment of dissection recently revived by uplift after a long period of relative quiescence. The details of valley form are incompletely described, though incidental mention is made of the incipient flood plains on the convex banks of the meandering streams, opposite the steep valley slopes over the concave banks. Many arithmetical details are given concerning the form of ridges and valleys: for example, the mean slopes of many valleys are calculated; although when the upper course of a valley is shallow and broad, slightly depressed beneath the uplands, while the lower course is sharply incised, relatively narrow and steep-sided, it is as inappropriate to measure its mean slope as it would be to average the price of old scrap iron and new steel rails. All these details have a certain value, but their value would be greatly increased if a more thorough scheme of physiographic description served as the basis of the work.

W. M. DAVIS.

NOTES ON OCEANOGRAPHY.

AN OCEANOGRAPHICAL MUSEUM.

IN connection with the exhibit of the collections made by the Prince of Monaco at the Paris Exposition, a convenient summary of his scientific work has been published by Richard (Les Campagnes Scientifiques de S. A. S. le Prince Albert Ier de Monaco, 1900). Brief descriptions of the different vessels and types of apparatus employed during the voyages, and a more

detailed résumé of the results, are given. Of particular interest in the contents of the pamphlet is the account of the magnificent building which is now nearing completion on the rock of Monaco, and intended to contain the great zoological and other collections of the Prince. The foundation stone was laid on April 25, 1899, by the Emperor of Germany. An idea of the size of the structure may be had from the fact that the façade will have the length of one hundred meters. While the greater part of the exhibits will relate to the biological sciences, there will be considerable space given to the illustration of apparatus, of the physical conditions of life in the sea, and of the areal and bathymetric distribution of organisms, by means of charts, diagrams, photographs, water-color sketches, etc. Appended to Richard's work is a valuable bibliography of the publications of the Prince and of his collaborators on the collections of the 'Hirondelle' and the 'Princesse Alice.'

MARINE CURRENTS AND RIVER DEFLECTION.

THE cause of the strong left-hand deflection of the Mississippi River below Baton Rouge has long been a matter of discussion (Fig. 1). The decided asymmetry of the delta both above and below sea level is an associated problem. Wind

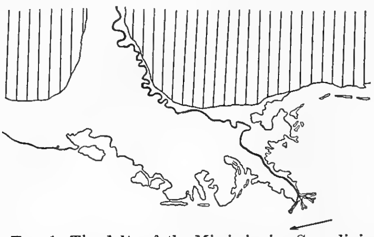


FIG. 1. The delta of the Mississippi. Cross-lining indicates older land. The arrow shows the general direction of the marine current prevailing at the river mouths.

direction, the influence of the Red River and crustal warping have been in turn appealed to in explanation of the facts. The formerly credited clockwise movement of the Gulf Stream in the Gulf of Mexico has likewise been held responsible. It is now generally agreed, however, that the prevailing direction of current movement is really westward past the mouths of the river. Haskell proved this by the use of the current meter on board the *Blake*. Lindenkohl's chart of densities plainly shows a transference of Mississippi water toward the west as it spreads out over the Gulf. The cause of the current is indicated in the prevailing easterly winds, as charted, for example, in the new Meteorological Atlas of Bartholomew. Corthell has noted a maximum speed of three knots for the west-flowing current.

In view of such strong and accumulating evidence for the current, it becomes of interest to inquire as to its influence on the form of the delta. The presentation of the case may suffice to call attention to a possible kind of interaction between river current and ocean current in the development of a very definite type of form.

Outside the river-bars, aggradation of the sea floor is progressing more rapidly on the west than on the east of the delta. The striking asymmetry of the delta is thus in part explained. The deeper water on the east will particularly facilitate the yearly advance of the bars on that side. But the direction of advance will be affected by a more positive cause. It is well known that the bar at each pass is breached during the flood season, and beyond the lower end of the new channel the delta is pushed forward for the remainder of the season. While the bar thus built in a new position is left essentially undisturbed by the river itself during the following half-year of low water, the transverse Gulf current (which is aided in the work by westward drift in the line of breakers on the bar) may be conceived as modifying the form of the bar during same period. The bar will be weakened on the left-hand extremity where the impact of the current is first felt, and strengthened on the right by the accretion of the silt traveling under the impulse of the current thus along the axis of the bar. The right-hand extremity of the bar will also tend to grow the faster in height and breadth, because of the sedimentation occurring in the low water season, since the river water over the bar is then borne upon the back of a west-flowing salt water wedge. The left-hand extrem-

ity of the bar, weak on account of the relative lack of deposition, and weakened by the transverse scour of the Gulf current, will invite the strengthening river-current of the next flood-time to break through the bar at that end. In this way, there will be a transference of the river axis, year by year, toward the left. In the meantime the delta has necessarily grown most rapidly to the right of the river-mouth.

The same phenomenon appears to be represented in the Rhône and the Ebro (Figs. 2 and 3).

FIG. 2. The delta of the Rhône. Symbols as in Fig. 1.

In each there are a pronounced leftward deflection of the river axis and a corresponding asymmetry of delta, coupled with a prevailing marine current sweeping past the river mouth from left to right. In all three cases, we have departures from the usual scheme of deflection, where the axis of the river is directed down stream with respect to the marine current. The conditions for this exceptional behavior are: (1) a powerful river characterized by a stable channel, and a delta growing so rapidly as to preserve one or more distributing arms; (2) a nearly tideless receiving water-body with a relatively steady current transverse to the river axis; (3) a volume of river sediment greater than that of the shore-waste migrating toward the delta under the impulse of the littoral current.

The shape of the bottom, the feeble tidal currents and the influence of mud-lumps probably have a small effect on the shape of the delta as a whole, but no other explanation is doubtless so weighty as that found in the force of the earth's rotation. In the northern hemisphere, it tends to produce left-hand deflection of an *aggrading* river. It is true that the rel-

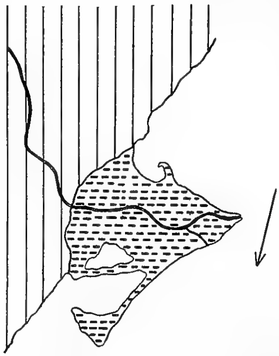

FIG. 3. The delta of the Ebro. Cross-lining indicates older land. Broken lines indicate alluvium. The arrow shows the general direction of the marine current prevailing at the river mouth.

ative straightness of river distributaries would permit of but a small proportion of the deflective force of rotation as affecting a meandering stream; but, small as it is, this force may be competent to produce strong asymmetry of a delta, since the friction of water against water is of a low order. It happens that in the three cases above noted, the marine current runs in a direction which would control the delta-building in the same sense as that expected from the influence of the earth's rotation. What is needed, among other tests of the current hypothesis, is a set of examples where the deflection of the river and delta is in appropriate relation to the corresponding currents, but in a sense opposed to that expected as a result of the earth's rotation. One purpose in outlining the hypothesis here in its present brief form is to invite observation on this point. Another obvious test is experiment. Some rough trials with artificial deltas, made on the tidal flats of the Annapolis Basin, Nova Scotia, seemed to confirm the hypothesis, but other and more thorough experiments are needed. Whatever be the explanation finally arrived at, it seems highly probable that this repeated occurrence

of deltas, possessing similar and rather highly specialized features, cannot be referred to merely accidental conditions governing the forward growth of the deltas.

R. A. DALY.

HARVARD UNIVERSITY.

THE NEW MEXICO BIOLOGICAL STATION.

THE Biological Station was founded as an independent institution at Mesilla in 1896. In 1899 it was moved to Las Vegas, and held a successful summer session in the New Mexico Normal University. A brief session was also held in 1900. The students in attendance have been mostly public school teachers. The results of the research work have been published in the *Annals and Magazine of Natural History.*

The Station will now be conducted as a part of the work of the biological department of the Normal University. The session of 1901 commenced on the 1st of June. A course in nature study is offered to public school teachers, and opportunities are afforded for research work along a number of different lines.

Las Vegas offers excellent opportunities for biological work. The summer climate is very good, and at no time is the heat excessive, as it is at lower altitudes in New Mexico and other parts of the Southwest. The altitude is about 6,400 feet, with mountains close by, rising above 11,000 feet.

Four distinct life-zones, the Upper Austral, the Transition, the Canadian and Hudsonian can be studied within 35 miles of Las Vegas. It results from this that the local fauna and flora are extremely rich in species; in the Hudsonian zone are forms of circumpolar distribution and others ranging to Alaska, though not to Asia or Europe; in the Canadian zone we find types identical with those of the mountains of the Northern States and of Colorado; in the Transition a varied assemblage typical, in part, of the foothill region of the Rocky Mountain range; in the upper Austral many species characteristic of the arid southwest, some ranging far southward and westward. With all this comes a certain percentage of local or endemic types, just how numerous further research must determine. Such are the snail *Ashmunella thomsoniana porteræ* and the magnificent butterfly *Argynnis nitocris nigrocærulea*, both found in Sapello Cañon.

The Gallinas River, flowing through Las Vegas, contains a crayfish (*Cambarus gallinus*), described as new last year, some interesting fishes (*Leuciscus* and *Rhinichthys*), and a variety of aquatic insects, algæ, etc. The Hot Springs, six miles away, contain some peculiar organisms, which have not yet been sufficiently examined.

In the Arroyo Pecos, and elsewhere in the immediate vicinity of the town, is an immense alluvial deposit of Pleistocene age, containing innumerable remains of mollusca and occasional mammalian fragments. Special facilities are offered to students of wild bees (*Apoidea*), the available collections and literature being very extensive. Facilities are also offered for the study of *Coccidæ* and other groups of insects. Students should, if possible, bring their own microscopes, slides, forceps and other accessories.

T. D. A. COCKERELL.

ANNOUNCEMENT CONCERNING THE THIRTEENTH SUMMER MEETING OF THE GEOLOGICAL SOCIETY OF AMERICA.

Sessions.—The thirteenth summer meeting of the Society will be held in Denver on Tuesday, August 27th, in the East Denver High School building. The Council will meet on Monday evening at the hotel headquarters. The Society will be called to order by the President, Mr. Charles D. Walcott, on Tuesday morning, immediately following the general session of the American Association for the Advancement of Science.

Program.—The preliminary list of papers will be mailed about August 1st, and no supplementary list will be sent. The Fellows are requested to send their abstracts on the printed form as promptly as possible, and not later than July 15th. By the rule of the Council abstracts are required. Papers offered for printing should be fully described on the blank forms, extra copies of which will be promptly sent on request.

Hotel Headquarters.—The Brown Palace Hotel has been selected by the local committee, A. A. A. S., as headquarters. The regular

rates at the hotel, are $1.50 per day and upwards on European plan, and $3.00 to $5.00 per day, American plan. Reduced rates will doubtless be made for the meeting.

Transportation.—The Western Passenger Association, covering the territory west of Chicago and St. Louis, has made a rate of one fare plus $2.00 for the round trip, in their territory, to Denver, Colorado Springs and Pueblo. The tickets may be bought from July 10th to August 31st, and are good for return up to October 31st. At this rate the fare from Chicago to Denver and return will be $31.50. The Pullman fare is $6.00 extra, each way.

Further details will be found in the A. A. A. S. circular, which will be issued soon.

Geological Excursions.—A circular has been sent to all Fellows, describing an extended excursion through Colorado planned by Professor C. R. Van Hise, Chairman of Section E, for the ten days (Aug. 17–27) preceding the meeting. For information concerning this trip request should be made to Professor Van Hise, Madison, Wis.

The Secretary of the Denver Local Committee writes as follows:

"Geological excursions which are likely to be arranged by the local committee are as follows, but subject to change: An all-day railroad excursion to Mt. Alto and Ward; one to the mesas at Golden; one to Morrison, to the Garden of the Titans, to study the magnificent exposure from the red beds of the Triassic to the uppermost beds of the Denver formation; to the classic ground where were obtained the first Atlantosaur and Stegasaurs; to the Pleistocene deposits near Denver. At Colorado Springs excursions will be taken to the Garden of the Gods; to the mineral springs at Manitou; and to the top of Pike's Peak. The greatest gold camps of the world, Victor and Cripple Creek, will also be visited."

The preliminary circular of the A. A. A. S. will be sent to Fellows of the Geological Society, who are not members of the Association, upon request to the secretary of the local committee, Mr. Arthur Williams, Denver Chamber of Commerce. All arrangements described in the association circular, relating to entertainment, transportation, etc., apply to the Geological Society and other societies which meet in conjunction with the Association. Details will be found in that circular which cannot be given here.

Express and Mail.—Matter for use at the meeting should be sent in care of the janitor, East Denver High School building. It should bear the shipper's address and be fully prepaid.

HERMAN LE ROY FAIRCHILD,
Secretary.

ROCHESTER, N. Y.,
June 7, 1901.

SCIENTIFIC NOTES AND NEWS.

AN official announcement has now been made in regard to the Rockefeller Institute for Medical Research, toward the establishment of which Mr. John D. Rockefeller has recently given $200,000. The directors are: William H. Welch, M.D., Baltimore, President; T. Mitchell Prudden, M.D., New York, Vice-President; L. Emmett Holt, M.D., New York, Secretary; C. A. Herter, M.D., New York, Treasurer; Theobald Smith, M.D., Boston; Simon Flexner, M.D., Philadelphia; H. M. Biggs, M.D., New York. The purpose of the foundation, as the name implies, is to furnish facilities for original investigation, particularly in such problems in medicine and hygiene as have a practical bearing upon the prevention and treatment of disease. The sum of money mentioned above is not an endowment, but may be used for current expenses. The Institute will be situated in New York City. A building will not, however, be erected at present, but research will be conducted in existing laboratories under the auspices of the directors.

PRESIDENT DAVID STARR JORDAN and Dr. Barton W. Evermann sailed from San Francisco on May 30th to conduct the investigation on the fishes of the Hawaiian Islands to which we have called attention.

PROFESSOR ASAPH HALL has resigned the lectureship in celestial mechanics at Harvard University, and will spend the next year or two abroad.

PROFESSOR HENRY F. OSBORN, of Columbia University and the American Museum

of Natural History, is at present in the Bad Lands of South Dakota, planning the work to be carried on this summer by the American Museum and the U. S. Geological Survey.

Dr. A. Smith Woodward, of the British Museum, has, since the beginning of April, been carrying on excavations at Pikermi, near Athens, where many interesting vertebrate fossils have been found.

Professor Stewart Culin, of the University of Pennsylvania, is at present on a visit to Cuba and Porto Rico. On his return he will visit the Indian tribes of the Northwest in the interest of the museum.

President James Loudon, of the University of Toronto, is at present attending the celebration of the University of Glasgow, and will later visit the universities of England and the Continent to obtain information for use in erecting the new science building of the university. During his absence Professor R. Ramsay Wright, of the chair of biology, is acting president. Principal John Galbraith, of the School of Practical Science, has been visiting the scientific schools in the United States, also with a view to the new building at Toronto.

At the last annual meeting of the American Academy of Arts and Sciences, $145 was appropriated from the C. M. Warren Research Fund to Dr. Charles H. Herty, University of Georgia, for purchase of material to be used in an investigation of the constitution of complex platinum compounds.

One of the Carnegie Research Fellowships of the Iron and Steel Institute of Great Britain has been awarded to Mr. John A. Matthews, who at present holds the Columbia University Barnard Fellowship.

The Soemmering prize of the Senckenburger Natural History Society, of Frankfort, has been awarded to Professor Franz Nissl, of Heidelberg, for his researches on the minute anatomy of the nerve cell.

The Director-General of the British Army Medical Service, Surgeon-General J. Jameson, C.B., retired on June 1.

The seventh Robert Boyle lecture at Cambridge University was delivered by Professor Sylvanus P. Thompson on June 6, his subject being 'Magnetism and Growth.'

Professor Volney G. Barbour, for thirty-one years professor of civil engineering in the University of Vermont, died in Minneapolis on June 4.

The eminent paleontologist, Professor Gustaf Lindström, keeper of the department of fossil animals in the Royal Museum, Stockholm, Sweden, died on May 16, last, at the age of 72 years. Dr. Lindström, who in 1876 was appointed successor of Professor N. Angelin in the Royal Museum, was well known among paleozoic investigators all over the world. He was an eminent scholar, and his works on paleontology and archeology are distinguished by their accuracy and thoroughness.

Dr. Karl Zeller, docent in theoretical astronomy in the German Technical Institute at Brünn, died on March 13, at the age of 46 years.

The following is a translation by Professor J. C. Branner, of Stanford University, of a decree issued at Pará, Brazil, by the Governor of that State in regard to the Natural History Museum, hitherto known as the Museu Paraense: "In view of the valuable services rendered by Dr. Emilio Augusto Goeldi, director of the Museu Paraense, in the organization of that important establishment, adapting it to the scientific purposes for which it was founded and enriching it by his efforts with valuable materials which have brought it to its present degree of prosperity; and considering that this distinguished official has dedicated himself with praiseworthy devotion to those subjects which bear upon the progress and improvement of this State, effectively contributing to its good name abroad; and considering that he brought to bear the valuable help of his scientific knowledge in the study and comprehension of our rights in the question of boundary with French Guyana: It is resolved, as a testimony of the gratitude of the State to the said official, to give to the Museu Paraense the name of the *Museu Goeldi.*"

Professor C. S. Sargent, of Harvard University, acknowledges the receipt of $126,485 for an addition to the endowment fund of the Arnold Arboretum.

MR. J. PIERPONT MORGAN has given to the Cooper Union Museum a collection of textile fabrics, the value of which is estimated at over $50,000. The collection, including the Bodia collection of Barcelona, the Rivas collection of Madrid and the Baron collection of Paris, very completely illustrates the history of weaving through the middle ages to the end of the seventeenth century.

ENGLISH journals report that the national collection of Lepidoptera in the Natural History Museum at South Kensington has recently been greatly enriched by the addition of the almost unique collection of butterflies from Europe, and Central and Eastern Asia, together with the collection of European moths, formed by the late Mr. John Henry Leech, of Hurdcott-house, Salisbury. Arrangements had been made during Mr. Leech's lifetime under which the museum became possessed of his eastern Asian moths, and now the same public institution has acquired the still more important accessions adverted to, through the munificence of his mother, Mrs. Leech, of Kensington Palace gardens. It is understood that the museum authorities will publish a catalogue of the butterfly collection. Of Rhopalocera there are rather more than 18,000 specimens, representing some 1,100 species, among which are over 400 male and female types of species described by Mr. Leech. This collection of Palearctic butterflies is very rich in Chinese and Japanese species, and in local forms and aberrations of European species. The European Heterocera number about 23,000 specimens, including some fine aberrations and extensive series of the variable species. The collection of eastern Asian moths, from which the museum had already made a selection, comprised nearly 3,000 species, of which about 800 were made known to science by Mr. Leech.

A MEETING was held in Dublin on May 17 for the purpose of advocating a pathological institute for Dublin. Delegates were present from various institutions, and plans were adopted for a laboratory intended primarily for research work.

As a return for the courtesies extended to members of the American Institute of Electrical Engineers during their visit to London last year, an illuminated address was prepared and was presented to the British Institution of Electrical Engineers on May 30.

THE American Medical Association, which met at St. Paul last week under the presidency of Dr. C. A. L. Reed, decided to meet next year at Saratoga. Dr. John A. Wyeth, of New York, was elected president.

THE third quinquennial Congress of Medical Men and Naturalists of the Czech and Slav nations was held at Prague on May 25 to 29, under the presidency of Dr. Jaroslav Hlava, professor of morbid anatomy in the Bohemian University at Prague. More than nine hundred members were in attendance.

THE Department of State has received a note from the minister of the Netherlands, dated Washington, May 22, 1901, stating that the Fifth International Congress of Criminal Anthropology will be held in Amsterdam from September 9–14, 1901. The principal questions to be discussed are: First, anatomical and physiological characters of criminals, descriptive studies; second, criminal psychology and psychopathology, criminals and lunatics, theoretical considerations and practical measures; third, criminal anthropology in its legal and administrative application, principles to be followed, preventive measures, protective measures, penalties; fourth, criminal sociology, economic causes of crime, criminality and socialism; fifth, criminal anthropology and ethnology compared. Special questions, such as alcoholism, sexuality, juvenile criminality, senile criminality, hypnotism, criminal psychology in literature, etc., will also be considered.

THE Geological Survey of South Dakota was treated more liberally by the last Legislature than in former years. It is therefore planned to prepare and publish soon a bulletin on the mineral resources of the State, giving the production for the year 1900, and, later, another on the water supplies, treating particularly of the Artesian areas. A reconnaisance is purposed for the coming summer into the region of the Moreau and Grand rivers. The persistent rumors of the occurrence of coal there will be investigated. As it is a region less known and

less settled than others, special attention will be given to the native plants and animals. The prevalent formations there are the Fox Hills of Hayden and the Laramie. The original localities of the former will be visited and collections made. The personnel of the Survey at present is as follows:

J. E. Todd, A.M., professor of geology, State University, Vermillion, *State Geologist.*

C. C. O'Harra, Ph.D., professor of geology, State School of Mines, Rapid City, *Assistant Geologist.*

C. P. Lommen, B.S., professor of biology, State University, Vermillion, *Assistant in Zoology.*

D. A. Saunders, A.M., professor of botany, State Agricultural College, Brookings, *Assistant in Botany.*

Mr. D. I. Bushnell is about to undertake a trip of reconnaisance to southwestern Missouri and northwestern Arkansas to examine caves in the White river region which is practically unknown to the archeologist.

We learn from the London *Times* that the Department of Agriculture and Technical Instruction for Ireland has, with the concurrence of the Agricultural Board and the Board of Technical Instruction, allocated a sum of £5,000 to the purposes of the Cork Exhibition, 1902, to be applied on condition that the general scheme of the exhibition is approved by the department. A portion of this sum will be devoted to the organization by the department of an exhibit of products, appliances, and processes relating to industries which are capable of being introduced into Ireland, or, where already established, of being developed on the most modern lines.

There was held last month in the Paris Jardin des Plantes, the first exhibition of useful plants cultivated in the colonies.

The French Jesuits of the Shanghaï Mission have for some time maintained a meteorological observatory at Zi-Ka-Wee, and they have now established an astronomical observatory on the summit of a hill about twenty miles distant. The two institutions are to be connected by wireless telegraphy. Father Chevallier is to have charge of the new observatory.

The mirror, being made by Mr. John A. Brashear for the reflecting telescope of Lick Observatory, was accidentally broken on June 5. It is feared that this will delay the expedition from the observatory to the Southern Hemisphere, as glass for a new mirror must be imported from France.

The New York *Evening Post* states that the Mexican government has refused to allow a collection of antiquities gathered there by Marshall H. Saville, assistant curator of the American Museum of Natural History, to be shipped out of the country. Mr. Saville returned about six weeks ago from a six months' trip in Mexico, and will go back to that country in September, when he expects to have the dispute adjusted. The Mexican law forbids the export of antiquities, but the Museum has a contract with that government by which it is empowered to take duplicates of specimens.

The government has decided to exclude immigrants suffering from tuberculosis.

Beginning with the present year Spain has adopted Greenwich time, which is 14 min. 46 sec. in advance of that of the meridian of Madrid which had previously been used.

It is planned to have an extensive exhibit of Röntgen ray apparatus at the meeting of German Scientific Men and Physicians which is this year held at Hamburg beginning on September 22.

According to the census taken on March 31, the population of England and Wales was 32,525,716, being an increase of 12.15 per cent. in ten years. The increase in the preceding decennium was 11.65. The percentage increase of London was only 7.3 per cent., its population now being 4,536,034. There has, however, been a large increase in the surrounding country, the population of Middlesex having nearly doubled. The population of Ireland is 4,456,546 and of Scotland 4,471,957. The change in the population of Ireland and of Scotland in the past sixty years is remarkable:

Year.	Ireland.	Scotland.
1841	8,197,000	2,620,000
1851	6,574,271	2,888,742
1861	5,798,967	3,062,294
1871	5,412,377	3,360,018
1881	5,174,836	3,735,573
1891	4,704,750	4,025,647
1901	4,456,546	4,471,957

The number of applications for patents in Great Britain last year was 23,922, as compared

with 25,800 in 1899. The highest point was reached in 1897 with 30,952. It is somewhat interesting to note that, while there has been a falling off in the number of patents granted to citizens in the United Kingdom and also to citizens of Germany and France, the number of applications from the United States increased from 3,002 in 1899 to 3,189 in 1900.

THE English papers state that a complete installation of Marconi's wireless telegraphy, specially suitable for signalling purposes as used in the navy, has been fitted on board the Elder, Dempster Beaver liner, Lake Champlain. This installation is the first which has been fitted on any of the Atlantic liners sailing from Liverpool. The Lake Champlain left the Mersey for Halifax on May 21, with over 1,000 passengers, and arrangements were made to establish communication between the vessel and the Marconi wireless telegraph station at Holyhead. At 9:37 P. M., when off the Skerries, contact was obtained with the Holyhead station, the vessel being then 13 miles distant. Numerous telegrams were then forwarded from passengers to friends in all parts of the United Kingdom, each message being acknowledged by the receiving operator. Constant communication with the station was continued until 1 A. M., the vessel being then 37 miles distant. Communication was established with the Marconi station at Rosslare, and at 4:30 A. M., a fresh batch of telegrams was forwarded, notifying the vessel's arrival off the Tuskar Light to the owners, Messrs. Elder, Dempster & Co.

ACCORDING to Reuter's Agency the ice-breaker *Yermak* will leave Kronstadt on May 29 for Newcastle, and, after coaling there, will proceed to Tromsö to cooperate in the fresh phase of the Spitzbergen expedition for the measurement of the terrestrial meridian. It is expected that by the end of June next she will be able to return to Tromsö and take on board Vice Admiral Makaroff, who is to direct the projected Arctic expedition. In the course of this expedition she will coast round Novaya Zemlya in order to determine precisely the outlines of that island. The *Yermak* will next inspect the state of the ice on the channel leading to the Yenisei River, in order to ascertain the correctness of the widely held theory that the passage to the Siberian rivers to the north of Novaya Zemlya is better than that by the Yugor Strait. Lieutenant Isliamoff, the astronomer, M. Weber, the geologist, and M. Vukuloff, the chemist, will take part in the Arctic expedition.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. ANDREW CARNEGIE has transferred $10,000,000 to trustees for university education in Scotland. The trustees include Lord Rosebery, Lord Kelvin, Mr. John Morley and other eminent Scottish citizens. It is expressly stated in the deed of gift that the fund is intended to improve and extend the opportunities for scientific research in the universities of Scotland and to facilitate attendance by paying the fees of students; and it is understood that the income will be divided equally between these two objects. The departments to be strengthened are science, medicine, modern languages, English literature and history.

IN view of Mr. Carnegie's great gift for Scottish universities, the following statistics regarding attendance and fees, published in a British parliamentary paper, are of interest. It will be noted that one-half of the income of the fund would pay all fees. The summer sessions, attended by 431 students, are not included.

Winter Session, 1899–1900.

	Men.	Women.	Total.	Fees.
St. Andrews.....	264	114	378	£2,934 4 6
Glasgow..........	1,604	329	1,933	13,597 10 0
Aberdeen.........	661	107	768	5,169 13 6
Edinburgh........	2,427	250	2,677	19,889 18 7
Total...............	4,956	800	5,756	£41,591 6 7

THE University of Glasgow has received subscriptions amounting to £38,000 toward an increased endowment. This sum includes an anonymous gift of £5,000 for the department of physiology. Among the donors of subscriptions of £1,000 are Lord Kelvin, Lord Rosebery and Mr. J. S. Kennedy, of New York.

COLUMBIA UNIVERSITY has received an anonymous gift of $20,000, of which $10,000 is for the purchase of books, $5,000 for a historical reading room and $5,000 for general purposes. Barnard College has received $1,500 for fitting up the zoological laboratory. Teachers Col-

lege has received an endowment for three fellowships of the annual value of $500 from Mr. John D. Rockefeller, and one from Mr. John Crosby Brown. These fellowships are to permit southern teachers to carry on advanced work.

Mrs. Philip D. Armour and Mr. J. Ogden Armour have added $250,000 to the $1,000,000 recently given by them to the Armour Institute, Chicago. A building for the Armour Memorial School of Engineering will be erected at once.

Carson-Newman College, a Baptist institution, of Tennessee, has collected an endowment fund of $60,000, of which Mr. J. D. Rockefeller gave $45,000.

A building for the scientific department of the U. S. Grant University, at Chattanooga, Tennessee, will be erected at a cost of $23,000. Of this sum the Hon. W. M. Banefield has given $5,000.

Elaborate ceremonies are this week in progress at Glasgow in connection with the ninth jubilee of the university. Among the events of special scientific interest are an address by Lord Kelvin on James Watt, who carried on his work at the old college, and an address by Professor John Young on William Hunter. The new botanical laboratories were to have been opened by Sir Joseph Hooker on the 13th. Delegates have been sent from the English universities and societies and from a number of American and foreign institutions.

At the annual commencement exercises of the University of Colorado, held in Boulder, Colo., June 6, 1901, seventy-four degrees were conferred as follows: 11 B.A., 17 B.Ph., 14 B.S., 1 B.L., 4 M.A., 2 M.S., 8 M.D., 12 LL.B., 2 B.S. (C.E.), 3 B.S. (E.E.).

The School of Pedagogy, of the New York University, has been reorganized. The Chancellor of University, Dr. H. M. McCracken, will act for the present as dean. Dr. J. P. Gordy, professor of education in the Ohio State University, has been called to the chair of the history of education and Dr. Robert MacDougall, of Harvard University, to the chair of experimental psychology. A number of professors of the University have been added to the faculty of the School of Pedagogy, including Professors J. J. Stevenson (natural history), D. W. Herring (physics), Morris Loeb (chemistry) and C. L. Bristol (biology).

Mr. M. N. Fenneman has been appointed professor of geology in the University of Colorado. He will begin his work in January next, at which time he will receive the Ph.D. degree from the University of Chicago.

At Harvard University, J. G. Love has been promoted to an assistant professorship of mathematics, and Albert Sauveur to an assistant professorship of metallurgy.

Dr. W. R. Stokes, city bacteriologist at Baltimore, has been elected professor of pathology in the College of Physicians and Surgeons of that city.

Dr. Francis H. Snow has resigned the chancellorship of the University of Kansas, but will retain the chair of natural history.

S. Gist Gee, professor of natural science of the Columbia (S. C.) Female College, has accepted a position in the Chinese University at Soochow.

Mr. Harold B. Hartley has been elected to a science fellowship at Balliol College, Oxford.

M. Déjerine has been appointed professor of the history of medicine in the University of Paris. There is some complaint because this chair is used as a stepping stone to other professorships. It is said that M. Déjerine will soon be transferred to a chair of nervous pathology and will be succeeded by M. Ballet who has undertaken to devote himself permanently to the history of medicine.

Dr. Wilhelm Salomon, associate professor of mineralogy at the University of Heidelberg, has been appointed director of the Institute of Paleontology and Stratigraphy and his title has been changed to associate professor of paleontology and stratigraphy. Dr. V. Hepperger has been promoted to a full professorship in astronomy in the University at Vienna. Dr. Wolf Müller has qualified as docent in chemistry in the University at Freiburg, i. B.; Dr. Jordis, in inorganic chemistry in the University at Erlangen, and Dr. Kallmann, in electricity in the Technical Institute at Berlin.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, JUNE 21, 1901.

CONTENTS:

The American Association for the Advancement of Science ... 961
A Kinetic Theory of Evolution: O. F. COOK ... 969
Miles Rock: WILLIAM EIMBECK ... 978
Otto Lugger: DR. L. O. HOWARD ... 980
Scientific Books:—
Pound and Clements on the Phytogeography of Nebraska: PROFESSOR ARTHUR HOLLICK. *Simpson's Synopsis of the Naiades:* PROFESSOR T. D. A. COCKERELL ... 981
Scientific Journals and Articles ... 984
Societies and Academies:—
Philosophical Society of Washington: CHARLES K. WEAD. *Torrey Botanical Club:* MARSHALL A. HOWE. *The Academy of Science of St. Louis:* PROFESSOR WILLIAM TRELEASE ... 985
Discussion and Correspondence:—
Remarkable Discoveries. An Earthwork Discovered in Michigan: HARLAN I. SMITH. *Physiology in the Schools:* PROFESSOR S. W. WILLISTON ... 987
Shorter Articles:—
What is Life? PROFESSOR JOSEPH LE CONTE. *A 'Sand Bow':* PROFESSOR JAMES E. TALMAGE ... 991
Notes on Inorganic Chemistry:—
Platinum in Antiquity; Lead in Pottery Glazes; Osmic Diffusion of Vanadium: J. L. H. ... 993
Current Notes on Meteorology:—
Annals of the Mont Blanc Observatory; The Moon and the Weather; Notes: R. DE C. WARD ... 993
Scientific Positions Under the Government ... 994
The American Association ... 995
Convocation Week ... 996
Scientific Notes and News ... 996
University and Educational News ... 999

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

A NATIONAL association for the advancement of science occupies at the beginning of the twentieth century a dominant position. The greatest achievement of the nineteenth century was the progress of science; its most definite tendency was towards the voluntary organization of individuals for the accomplishment of certain ends. The advance of science, the movement that is of the greatest importance for civilization, requires for its guidance the strongest association of individuals. Such an association will certainly arise, and will develop from existing institutions.

The organization of science in America has progressed parallel to the advance of science. Local societies concerned with the whole field of knowledge, and especially with its utilitarian aspects, were first established in Philadelphia, in Boston and in other cities. These societies were modeled on the similar institutions of Europe; the Philosophical Society of Philadelphia following the Royal Society of London, and the Academy of Arts and Sciences of Boston, the Paris Academy of Sciences. As centers of scientific activity increased in number,

as the postoffice and railways developed, as general scientific journals were established—*The American Journal of Science* began publication in 1818—the need of a national organization was felt, and here again the older nations had established the precedent. The meetings of German scientific men and physicians began in 1828, and the British Association for the Advancement of Science was established in 1831. An Association of American Geologists and Naturalists was organized in 1840, and became the American Association for the Advancement of Science in 1848.

Fifty years ago the sciences were comparatively undifferentiated. Special societies and special journals were not required. It was possible for students of science and friends of science to meet together and take a common and intelligent interest in the scientific progress of the day. Somewhat later, however, the need became apparent for a more select national society. The local academies in the European capitals had become national institutions in a way that was not possible for the similar societies in the United States, owing to the lack of centralization. Our National Academy of Sciences was organized in 1863 with a membership at first limited to fifty, and still under one hundred. The Academy was intended to be the adviser of the Government in scientific matters, and has to a certain extent fulfilled this function. At first, when there were but few scientific men in the United States and their interests were more or less common, the National Academy was an organization fitted to its environment. But it has scarcely adjusted itself to the growth and specialization in science of the past twenty-five years.

The organization of science that was adequate for the third quarter of the century did not suffice for the fourth quarter. About twenty-five years ago it became necessary to meet the specialization becoming inevitable for scientific advance. Special societies and special journals were organized. The American Society of Naturalists, organized in 1883, and the *American Naturalist*, established in 1867, covered a limited, but still wide, field. SCIENCE, a weekly journal, was established in 1883 to keep the sciences in touch with each other and men of science in touch with the general public. The American Chemical Society was organized in 1876, The American Ornithologists' Union in 1883, The Geological Society of America and the present American Mathematical Society in 1888, and there are now national societies for almost every science. Special journals were established during the same period—*The Bulletin of the Torrey Botanical Club* (1870), *The Botanical Gazette* (1876), *The American Journal of Mathematics* (1878), *The American Chemical Journal* (1887), *The American Journal of Morphology* (1887), *The American Journal of Psychology* (1887), *The American Geologist* (1888), *The National Geographic Magazine* (1888), *The American Anthropologist* (1888) and so on, in increasing numbers, to the present time. A similar movement toward specialization is evident in the development of elective courses in our colleges, of advanced work in our universities, and in many other directions.

The American Association for the Advancement of Science did not fail to adjust

its organization to the growth and differentiation of science. In 1875 a formal division was made into two sections, one for the exact and one for the natural sciences, and in 1882 nine sections were established. At this time, when the Association had fitted itself to existing conditions, it enjoyed a most prosperous period in its history, the meetings being large and fruitful. Thus the attendance at Boston in 1880 was 997; at Montreal in 1882 it was 937, and at Philadelphia in 1884 it was 1261. But with the organization and growth of the special societies and journals referred to above, the Association did not maintain its commanding position. The American Society of Naturalists, with a more compact membership, chose midwinter as its time of meeting, and other societies became affiliated with it. The special societies, consisting of groups of experts, appealed to the loyalty of their members more directly than did the larger and more amorphous Association. There was lack of sympathy between these societies and the Association. The attendance at the meetings became smaller, and the total membership decreased. Many eminent men of science and many younger workers were not regularly in attendance at the meetings and were perhaps not even members of the Association. The programs of the sections became heterogeneous and sometimes did not reach a very high standard. The amateur and picnic elements were rather prominent, while at the same time they were mediocre. Many men of science regarded the Association as a survival that had outlived its usefulness.

But to-day no one acquainted with the most recent work of the Association will deny that it has entered on a new period of its history. This began with a change of attitude toward the special societies, replacing rivalry with cooperation. There was much opposition to the plan of letting the American Chemical Society meet in affiliation with the Association, but when this was accomplished chemistry at once became its strongest section. So it has been in other cases, where special societies have met in affiliation with the Association. At the recent New York meeting there were sixteen such societies, including practically all national societies that hold summer meetings. Other improvements in the organization of the Association have been effected. The council has been strengthened and made a truly legislative and executive body. The permanent funds have been increased, and appropriations for research have been granted to committees. Care has been exercised in the election of fellows, and in the admission of titles to the programs. This Journal is sent free of charge to all members, thus increasing and consolidating interest in the Association and in the advancement of science, giving even those unable to attend the annual meetings an adequate return for membership, and tending to unite all men of science and those interested in science in the Association and in the ends that it represents. The last three meetings, held at Boston, Columbus and New York, were all excellent, representing different types adjusted to the occasion and place. The meeting at Denver this year will be equally typical and

equally successful. The membership of the Association is now larger than it ever was before, over eight hundred new members having been elected within the past year.

There is every reason for satisfaction at the present condition and outlook of the Association. But this does not mean that we need not be on the alert to increase its usefulness under the circumstances confronting us at the beginning of the twentieth century. Evolution occurs by natural selection, but with boundless waste, regardless of time and careless of the individual. Human development must henceforth be guided by forethought and reason. It is the object of this article to make some definite suggestions regarding the organization of science in America under the auspices of the Association. They have been carefully considered by some of those most interested in the Association and, though they may not meet with universal approval, they are thought to be worth careful consideration.

The objects of the Association are said in its constitution to be "by periodical and migratory meetings, to promote intercourse between those who are cultivating science in different parts of America, to give a stronger and more general impulse and more systematic direction to scientific research, and to procure for the labors of scientific men, increased facilities and a wider usefulness." This statement may be somewhat systematized and amplified. The legitimate objects of the Association may be said to be (1) the presentation and discussion of research work in the different sciences and the publication of such research. (2) The promotion of research by grants of money and by providing the means for cooperation. (3) The encouragement of addresses, reports and publications on the progress of different departments of science, sometimes of value to the specialist, but more especially important in keeping the sciences in touch with each other. Joint meetings, discussions and publications should be arranged on subjects common to different sciences, relating the pure and applied sciences or concerned with science as a whole. (4) The presentation of such addresses, reports, discussions and publications in a form that will so far as possible keep the general public informed on the advances of science, interest them in the opportunities of scientific work and its needs, and impress on them the dignity and supreme importance of science. Here should be included whatever will secure recruits to scientific workers and the money and support that scientific work requires. (5) Offering an opportunity for men of science in different departments to become acquainted personally and by publication, and encouraging sympathy and loyalty to their common interests, and performing, so far as possible, the same function for scientific men and the intelligent public. (6) The guidance of scientific organization in America, which includes the coordination, establishment and arrangement for the meetings, etc., of special scientific societies; the publication and circulation of scientific books and journals; the place of science in education and all external means for the advancement and diffusion of science; the direction of public opinion and legislation

on science, more especially when connected with the national government, and the different states and municipalities; the promotion of conditions required by science and of reforms recommended by science—in general, whatever will promote the advancement, diffusion and usefulness of science.

1. The first of these functions has in large measure been assumed by the special societies and journals, and this is in accordance with necessary conditions. Special research must be presented before, and discussed by, small groups of experts and must be published in journals that are of interest only to specialists. The special societies have compact organizations; they are most competent to select their membership, to arrange their programs and to conduct their publications. It seems inevitable that the Association must relinquish its function of providing sections for the presentation of special papers, except in the rare case that a special society does not exist and may be formed by the aid of the Association. In a joint meeting of a special society and the corresponding section all the valuable papers will be presented both before the society and the section, and only such papers will be presented to the section alone as the society will not admit. There is, however, no reason why the present general organization should not be maintained, and the papers read before the affiliated societies be made part of the proceedings of the Association. The Association may, however, render important assistance to the special societies in the ways indicated below.

2. The promotion of research by grants of money and by providing the means for cooperation is a function that should be undertaken both by the special societies and by the general Association. The latter is, as a matter of fact, more likely to secure funds for this purpose by bequests and gifts, owing to its national character, its long history and its permanence. It can to special advantage further researches in which more than one science is concerned and in which independent societies might fail to cooperate. Efforts should be made to increase the number of patrons of the Association and to secure bequests and gifts, in order that the American Association may not be behind the British and French Associations, which appropriate annually $5,000 or more for the direct encouragement of research. Invested funds yielding an income for this purpose would add greatly to the stability, influence and usefulness of the Association, and to the interest of the meetings at which the grants are made and the reports of the work accomplished are presented.

3. The special societies may with advantage present addresses and reports on the progress of a science, and, when the societies meet at the same time and place, their value is increased by the opportunity afforded for a larger group to be present. In this direction the Association has, however, an important work. The address of the president, the most eminent man of science in America who has not yet held this office, should be an event of national importance. It should be worth publication, and should be published in full in all the important daily newspapers, as actually happens in

England in the case of the president of the British Association. The addresses of the vice-presidents should be as nearly as may be of the same importance and interest. These should not be addresses such as are presented before the special societies, but should be intelligible and interesting to all men of science and to the great mass of men and women who have had a college education or an equivalent training in affairs. The afternoons through the week might with advantage begin with these addresses, not more than two being given simultaneously, and these might be followed with reports or discussions of problems of general interest. The sectional committees and the council should pay special attention well in advance to the arrangement of a program. Care should be taken, if necessary by invitation to those not members of the Association, to secure the adequate presentation of subjects in which the Association needs strengthening. Thus applied science should be given more prominence than hitherto. Those eminent in public life, in educational work and the like, and distinguished foreign men of science, might be invited to address the Association or to take part in its discussions. Funds should be available to defray at least the traveling expenses of such invited guests.

4. The addresses, reports and discussions should, in part at least, be of such interest as to attract the general public, securing a large local attendance and being reported widely by the press. It is not possible, least of all in a democratic country, for science to isolate itself from common life. There must be special research that can be appreciated only by the expert, but as quickly as possible the progress of science should be made a part of the world's common stock of knowledge. The American Association should be one of the chief factors in the diffusion of science, and its annual meetings should be looked forward to by the general public as the occasion when for its benefit the year's progress in science and the contemporary state of science are exhibited in their outlines and in correct perspective. The meetings should typify the dignity and weight of science, so as to impress these on the minds of all. The sympathy and support of all the people are absolutely essential for science. Only so can recruits for scientific work be secured; only so can endowments and material support be obtained; only so can scientific work under the government be placed on a secure and permanent basis. We have in these needs not only the justification, but the absolute necessity of an Association with a large membership—it should be at least ten thousand—drawn from the intelligent people of the whole country.

5. The social intercourse and personal contact of scientific societies and meetings are among their most important functions. Men in isolation become selfish and incompetent. Even a great genius does not work in solitude, and certainly the ordinary man requires the interest and enthusiasm that is only evoked in the give and take of personal acquaintance and conversation. Eating together, drinking together, smoking together, may have physiological drawbacks, but the psychological stimulus has war-

ranted the origin and survival of these practices. Those studying similar problems, and those working in diverse directions; the university professor, the school teacher and the government officer; those who call their science pure and those who seek to make it useful; the beginners and the old benchers, all should be thrown together, ready to learn and help, to agree and differ. Each should be prepared to profit much, and if need be to sacrifice a little for the common good. The meetings of the Association do, of necessity, accomplish a great deal in bringing men together, but perhaps not all that could be desired. The cultivation of personal acquaintance between professional men of science and the amateur and outsider is also important, but more difficult to manage. The social features of the British Association seem to be more successful than our own. A thousand or more of the leading citizens of the place become temporary members for each meeting, and freely offer entertainments of one sort or another. The social conditions are, of course, different in America, but it seems that the entertainments and excursions might be made more pleasant and profitable in the future.

6. Of all the important functions of a national scientific association, the most essential is the general organization of science. The science of the country absolutely requires a central legislative body. Such bodies exist in other nations, having varying degrees of usefulness, and there is more need of an active and efficient representation of scientific interests in the United States than in any other country. London, Paris and the other European capitals, with their societies, clubs, etc., bring together all the scientific men of the country, whereas here they are widely scattered, and will become still more so as the East loses its intellectual precedence. Washington will doubtless be our chief center for scientific research, but under our system of State governments and with our privately endowed institutions, it is not likely that it will occupy the position of European capitals. The great development of scientific work under the national government, the numerous smaller centers under the State governments at their capitals and universities, the municipalities with their increasing tendency to support museums, libraries, etc., and to undertake functions requiring scientific experts, the great incorporated universities developing special research, the applications of science in industries, transportation, etc.—all these represent an extraordinary activity, and, at the same time, a dispersion of tendencies and interests that require here more than in any country some unifying and centralizing organization. The functions of such a body are only limited by its efficiency. Our government recognizes a division into executive, legislative and judicial functions, but does not recognize the coordinate importance of expert opinion. As the judicatory interprets the laws made by the legislature, so the legislature requires impartial advice and scientific knowledge as the basis of its enactments.

The question now arises as to what body or bodies should perform the functions thus outlined. In the first place, it is evident that we need numerous and partly inde-

pendent institutions. Each university, museum, survey, observatory, botanical garden, laboratory and the like is a unit, requiring its special organization. Each city should have a local academy, or alliance of societies, which in its field should perform most of the functions that we have been considering. Similar academies, or groups of societies, are needed for a State or region. National societies are required for each science. But what should be the national organization that will bring all the local and special societies together, and accomplish for the nation and for science as a whole what these institutions and societies do for a locality or a single science? We have at present the National Academy of Sciences and the American Association for the Advancement of Science, both of which have to a certain extent filled these requirements, but only in a partial and imperfect way. The Academy is legally the adviser of the government, the Association has brought into its organization a majority of the scientific men and many of the scientific societies of the country; but it seems probable that neither a small self-perpetuating body of eminent men nor a plebiscite of all scientific men will perform the duties required. Representative government, in spite of its partial failures, is the kind of government under which we should live and must live. We find this most nearly embodied in the council of the American Association. This council might be made the representative body for science in America.

If it be asked what the American Association and its council should do to assume the position assigned to them, the reply may fortunately be made: Let them continue the work that they have already begun. The whole matter is one of attitude and spirit, rather than of constitution and by-laws. Let all scientific men be fellows of the Association, make the members representative of the intelligence of the country, unite all scientific societies and institutions in the organization of the Association, make the meetings important and interesting, let the council assume and deserve authority.

While the position of the Association must depend chiefly on natural fitness and development and on the spirit and character of its members, there are certain changes in organization that deserve consideration. We shall suggest some modifications which appear to be either desirable at present or objects to be kept in view.

Affiliated societies should be represented on the council, and all scientific societies, whether national or local, should be affiliated with the Association. The number of representatives allowed from each society should be proportional to the number of members of the society among the fellows of the Association. For example, each institution having ten fellows might be allowed a representative and an additional representative for each additional twenty-five fellows. This plan includes the representation of local academies, universities, government departments, etc., on the council, but might begin with the societies meeting with the Association, in accordance with an amendment to the constitution now pending. It might be well for the

council to elect each year three additional members to serve for a term of three years. Those so elected would probably be among the most efficient members of the council. The council would thus be considerably enlarged, but its authority would be greatly increased. It is of course understood that the real work of legislative bodies is done by committees, and the committees of the council should be organized with special care.

The executive officer of the Association is the permanent secretary, and his influence should be very great. He should either be paid a reasonable salary, say $5,000, and devote his whole time to the Association and the organization of science in America, or should be, as our present secretary, a man of unusual executive ability, having under him one or two assistant secretaries who should devote themselves to the work. The secretaries of the sections should be among the most efficient members of the sections, and should be elected for a term of three years and reeligible.

The meetings should be more thoroughly organized in advance, more authority being vested in the permanent secretary and council. As suggested above, public lectures and discussions on the important advances and current problems of general interest should be arranged. For example, this year there should be reports on the relation of mosquitoes to disease, on the newly established Bureau of Standards, on the conduct of a national observatory, on the natural history and resources of the West Indies and the Philippines, and, in view of the place of meeting, on mining and irrigation.

The time of meeting has always interfered with success. Men of science will not and and can not come together at midsummer. If a week can be set aside at the beginning of the year, it is probable that the scientific character and weight of the meetings will be greatly forwarded. The importance of obtaining a convocation week in midwinter has been emphasized in a recent editorial (April 26, 1901), and we are now able to report that, of the fourteen universities comprising the Association of American Universities, all but two either already have no exercises at the time or have altered their calendars in the direction of setting aside the week in which New Year's Day falls for the meetings of scientific and learned societies. It might, however, be well to have, say once in three years, a summer meeting in which the social and excursion elements should be emphasized. It must be remembered that the National Educational Association can bring together 10,000 members in this way. Or perhaps, it will be found with experience that the winter meeting is so advantageous that the summer meetings can be omitted altogether. Meanwhile there might be suggested a special meeting at Chicago next year at Christmas time in conjunction with the Naturalists and affiliated societies, the usual meeting at Pittsburg in midsummer, and a meeting of unusual importance at Washington at the end of the year.

*A KINETIC THEORY OF EVOLUTION.**

IN 1895† the opinion was expressed that the differentiatión existing in certain fami-

† *Proc. U. S. Nat. Museum*, 1895, 18 : 64.

lies of Chilopoda represents the results of variation accumulated without the interference of natural selection. In the next year* the same proposition was applied to the class Diplopoda, and studies in other groups, such as the termites, fungi, hepaticæ, mosses, ferns and flowering plants have led to the belief that there is little ground for the supposed stability of organic form and structure which furnished the basis of the doctrine of the separate creation of species, and which still figures as an important postulate in theories of evolution through natural selection. The Diplopoda are one of the many classes of animals and plants in which ecologic relations are essentially different from those of the mammals, birds, and other highly specialized groups upon which evolutionary studies have largely been based. Among the Diplopoda are to be found very few of the adaptations so numerous among the true insects; Diplopoda do not eat each other, and are not eaten by other animals;† their food requirements are not specialized, and decaying vegetable matter is generally abundant far in excess of their needs. There is seldom a suggestion of a struggle for existence or of other conditions indicating an active principle of selection. At the same time there is no lack of morphological differences, and while the present or past absence of selective influence in any particular character cannot, of course, be demonstrated, the phylogenetic, biologic and ecologic unity of the group, when contrasted with its structural and evolutionary diversity, seems to justify the opinion that in this class, at least, evolution is a kinetic phenomenon or active process of organic change, instead of the result of a passive subjection to external interference in otherwise stable conditions.

EVOLUTION BY INTEGRATION.

Examples of groups of characters which it seems impossible to look upon as of selective origin have been noticed in another place.* Moreover, it is scarcely necessary to detail particular instances, since for a proposition partaking of the nature of a general law every biologist should find ample supporting evidence inside the field of his own specialty. Kinetic evolution is, indeed, nothing new, and requires for its formal recognition little beyond the most obvious facts of natural history; doubtless it would have been appreciated and accepted years ago had not makers of static theories protected themselves against so simple an inference by inventing the so-called principle of panmixia, under which it is argued that spontaneous progressive change is impossible in a large group of individuals, because fortuitous variations occurring simultaneously in all directions are brought back to a stable average by intercrossing.

In reality, however, this proposition is worthy of little of the deference due to a mathematical axiom; biologically it rests on unproved and apparently unprovable assumptions. We have by no means ascertained that the individuals of a species tend to vary equally in all directions with respect to all their characters; on the contrary, some variations are much more common than others. We have not ascertained that the crossing of individuals showing different variations always results in average offspring; we know instead that the next generation often exceeds both its parents in the accentuation of some new characteristic. In its logical development panmixia, if true, would constitute a demonstration that individual variation acting through heredity cannot contribute to the evolutionary progress of a species; it is as

* 'The Diplopod Family Oxydesmidae,' a paper prepared for the Proceedings of the U. S. National Museum.

though individual influence were a wave raised by a pebble, and not a permanent elevation of level. Individual differences could in this view affect the evolution of species only when interbreeding is prevented by some form of isolation, a supposition which has received apparent support from the finding of many distinct species in small islands or other circumscribed localities. That isolation tends to the rapid *differentiation of specific types* affords, however, no proof that *progressive change* is due to isolation, geographical or selectional. That a certain peculiarity is manifest in all the individuals of an insular or strictly circumscribed species may mean, not that all the individuals are descended from a single peculiar ancestor, but that the change tendencies which have originated in this locality have been confined to it, and have not been able to propagate themselves beyond the natural barriers.* In the absence of such limits specific differentiation might not have taken place, but evolutionary progress might have been greater by reason of access to more varied developmental tendencies. Specific differentiation thus affords but little indication of the rate or nature of evolutionary progress, which often appears not to be the result of isolation at all, but rather of the aggregation and integration of individual variations welcome to the organic constitution. In this aspect of the subject isolation may be viewed as the absence, rather than as the result, of selection.

* The stability or fixity of type which has been ascribed to small segregations of plants and animals is only relative, even under careful artifical selection, and from the standpoint of biological history is to be interpreted as uniformity rather than as permanence. Among the molluscs, which have been supposed to furnish examples of great permanence, very diverse animals are now known to inhabit shells of extreme similarity. Evidently the external skeleton is not an adequate index of evolutionary status: in some families variation seems to have principally affected the shells, in others the softer parts.

Species, which have been thought to support the opinion that selection brings about evolution by inducing various degrees and kinds of isolation, can often be much more rationally interpreted as instances of the manifestation of spontaneous developmental tendencies. Groups like the Diplopoda illustrate the infinity of combinations of characters possible without the assistance of any of the influences commonly invoked to explain the specializations of the more adaptive organisms, and thus permit us to realize that evolution is one of the causes, instead of a result, of biological isolation, the effects of which are probably limited to specific differentiation.

To have confidence in organic evolution accomplished by selection and isolation in the presence of an efficient panmixia would require at least double the credulity needed to equip the earth from the original pairs of the Garden of Eden or of Noah's Ark, since the ancient accounts provided two parents for each species while the modern begins with one, the offspring of which must be placed under such conditions that they are prevented from mixing with the parental type, either by means of geographical separation or through circumstances which give the variety immediate and exclusive advantage over the older forms. The only alternative would involve the origin of species from sports so extremely divergent that their offspring would remain distinct after considerable dilution with the parent form. The maintenance of such differences through the prepotency of new types, in accordance with the kinetic view, could not, of course, be invoked under theories accepting panmixia.

Moreover, it should not be forgotten that all segregations of small numbers of individuals involve the necessity of close breeding, which has been found in domesticated animals and plants to lead in many instances directly toward abnormal and

even pathological characteristics, and which is also commonly recognized as weakening vitality and vegetative strength. Thus many high-bred varieties of plants are nearly or quite seedless, while in others the germinating power of the seed is very low, facts that afford a strong indication that general evolutionary progress has not been greatly favored by segregation.

Although the breeding of domestic animals and plants has generally been directed toward the accentuation of some one feature or limited group of characteristics desirable for economic reasons, it should be remembered that, in nature, evolutionary progress must carry with it improvement in total organic efficiency, which in turn depends upon almost an infinity of morphological and physiological coordinations, the perfection of which would be assisted rather than hindered by the access to a great variety of evolutionary tendencies or suggestions.

From the evolutionary standpoint a species is not a definition or a complex of characters, more or less important, but a group of organic individuals which stand in a definite biological relation of reproductive accessibility. Species do not arise and are not separated in nature primarily by the degree or amount of difference which may exist between individuals; in some groups species contain greater diversities than appear elsewhere between genera, families or orders. Interbreeding prevents the subdivision of species, but at the same time conduces to variety instead of maintaining stability. Species become distinct in nature not only when the component individuals are separated by geographical or other forms of isolation, but accumulated variations may themselves bring about isolation when evolutionary tendencies become so divergent that further coordination is difficult, and interbreeding ceases. Evolution is thus a process of integration rather than of segregation, and organic progress, like intellectual and social advancement, is not an individual phenomenon, but the accumulated result of individual contributions which are not lost, but saved, by interbreeding or communication to others. Isolation permits the accentuation of individual peculiarities, but does not on that account conduce to intellectual or social development; selection may encourage specialization, but it often limits the field of subsequent changes and adaptations necessary for the perpetuation and continued welfare of the species.

The various forms of selection and isolation represent, as it were, the outside of evolution, the points at which it is affected by external accidents. Organic development is not, however, a passive, but an intensely active process; selection and isolation have not caused evolution, but are among the conditions under which it sometimes proceeds.

The crossing of geographically distinct species often results, not merely in the production of intermediate forms, but in new types having characters not represented in either of the parents, and since the same result often follows the crossing of divergent forms of the same species, we have a further reason for believing that progressive change is not dependent upon, but may even be impeded by, selection and isolation, and that interbreeding rather than segregation is favorable to evolutionary progress. Static theories have thus reversed the true functions and effects of panmixia and isolation.

DARWINISM AS A STATIC THEORY.

Phylogeny and ecology were combined by Darwin as different sides of the same phenomenon, and environment was held at once to cause variation and to produce indefinitely extensive changes by means of it —a theory here described as static because

it predicates the normal stability of organic series.*

The configuration of a valley may determine the banks of a river which flows through it, but the valley does not cause the water to run down hill. In the absence of this property of water valleys would be quite powerless to 'give rise' to rivers. Similarly, it is true that environment influences organic evolution; it may accelerate or retard, deflect or even set absolute barriers to change, but these facts afford no reason for believing that selection represents a biological force. The vital river, when unconfined, is in motion; change is a law of organic succession; evolution is a property of protoplasm.

Some rivers have direct courses, deep channels and swift currents; the water reaches the sea without much loss of time; with such streams is comparable the evolution of the organic groups which an active selection has kept well within the lines of utility, whose functional organization is so perfect that a useless structure or an unprotective color is looked upon as an anomaly requiring special explanation. There are, however, other rivers the waters of which give no suggestion of haste: they meet innumerable turns, eddies and backsets, they are divided by islands, and often overflow the land. With such rivers may be compared the evolution of groups like the Diplopoda, not confined by too exact requirements of utility, and hence the better able to manifest the natural tendency to indefinite change.

Darwin and Wallace recognized the fact that a species does not constitute a single morphological point, but that the projection of its characters requires a surface of appreciable area. And assuming that there is a tendency or law by which such an area remains even approximately constant in size, they found that it could be given a progressive motion by taking away from one side while permitting the other to grow out. Thus it appeared possible by predicating external causes to explain evolutionary progress with but a slight readjustment of the traditional static view of organic

* "But let the external conditions of a country alter * * * the original inhabitants must cease to be as perfectly adapted to the changed conditions as they were originally * * * such changes of external conditions would, from their acting on the reproductive system, probably cause the organization of those beings which are most affected to become, as under domestication, plastic. Now, can it be doubted, from the struggle each individual has to obtain subsistence, that any minute variation in structure, habits or instincts, adapting that individual better to the new conditions, would tell upon its vigor and health?.* * * Each new variety or species, when formed, will generally take the place of, and thus exterminate, its less well fitted parent. This I believe to be the origin of the classification and affinities of organic beings at all times; for organic beings always *seem* to branch and sub-branch like the limbs of a tree from a common trunk, the flourishing and diverging twigs destroying the less vigorous, the dead and lost branches rudely representing extinct genera and families."

Quite as definitely did Wallace state the same proposition in controverting the somewhat more narrowly static idea that the variations of species are limited, as it were, to fixed points beyond which they cannot go in nature, or to which they must return if differentiated from the wild type by artificial selection.

"But * * * there is a general principle in nature which will cause many *varieties* to survive the parent species, and to give rise to successive variations departing further and further from the original type, and which also produces in domesticated animals the tendency of varieties to return to the parent form. * * * Granted, therefore, a 'tendency' to reproduce the original type of the species, still the variety must ever remain preponderant in numbers, and under adverse physical conditions *again alone survive.* But this new, improved, and populous race might itself, in course of time, give rise to new varieties, exhibiting several diverging modifications of form, any one of which, tending to increase the facilities for preserving existence, must, by the same general law, in their turn become predominant. Here, then, we have *progression and continued divergence* deduced from the general laws which regulate the existence of animals in a state of nature, and from the undisputed fact that varieties do frequently occur."

life, a view which thus persisted and is still generally held.

Subsequently, both Darwin and Wallace admitted progressive variation without natural selection, which was considered to be but one of several factors contributing to evolution. The original statement, however, continues to represent Darwinism in the scientific world, and, as has been well said,* "The biologist of to-day is more Darwinian than Darwin, and explains on the Darwinian hypothesis even those cases which had presented difficulties to Darwin's own mind." This tendency signifies that the inadequacy of all other explanations has become more and more thoroughly realized, thus causing a return to Darwin as the author of the only real contribution to the study of biological causes. The static or selective theory of evolution has, however, attained its present popularity, not because it has been shown to have any universal application in nature, but because it has remained the only suggested explanation which seemed to be supported by definite and particularized phenomena.

VARIATION AND CONJUGATION AS KINETIC PHENOMENA.

It is probable that in the study of biological motion it will be found desirable to distinguish at least four types of variation or kinds of differences between closely related organisms. Some modifications may be described as mere chemical or physical reactions to definite substances, forces or conditions; † some are more clearly pathological and are the result of inherent weakness or derangement of the organism; while others are normal vibrations or fluctuations of form, size, color or other characteristics having, perhaps, no very definite single cause, nor any pronounced tendency to repeat themselves. Essentially different, though often confused with one or the other of the above, are the peculiarities which represent lines of change or divergence, upon which the organic series if unhindered may proceed with no diminution, but rather with an increase of structural and physiological efficiency, and often with persistence and rapidity. To this class belong the 'sports' which come true to seed and yet show no signs of debility, and which, though crossed with the parental type, impress their characters upon a large majority of the offspring. In other words, variations of this kind are prepotent because they open avenues of advance and adjustment welcome to the organism and necessary to the maintenance of the efficiency of protoplasmic structure and function.

Variation and conjugation may thus be supposed to minister to the same requirement of the protoplasmic organization. There is little or no warrant for the current belief that variation and heredity are phenomena essentially connected with sexual reproduction, and thus explainable through a knowledge of the structure and mechanism of conjugating cells. In final analysis reproduction is not a sexual but a vegetative process. Because in some groups the conjugation of nuclei is an indispensable preliminary to reproduction,* the most

* Haycraft, 'Darwinism and Race Progress,' London, 1900, 28.

† According to Professor Osborne: "When the pale *Proteus* is taken from the Austrian caves, placed in the sunlight, and in the course of a month becomes darkly pigmented, there are two interpretations of this pigmentation; either that we have revived a latent character, or that we have created a new character." *American Naturalist*, May, 1899, p. 431. It would seem, however, that this experiment may prove neither of these alternatives, but merely that the skin of *Proteus* is capable of the photic reaction which generally influences the formation of pigment.

*SCIENCE, N. S., 1900, XII., pp. 940–946. In this presentation of Professor Hertwig's views the issue is still obscured by a residue of the former terminology. Thus on page 943 we read that "the sexual reproduction of Metazoa is a continuation of the method of reproduction in the Protozoa, while the budding and

intimate of causal relations have been inferred, in spite of the existence of many forms of reproduction not so preceded. From the morphological standpoint there is every gradation from parthenogenesis or the development without fertilization of cells which are normally fertilized, to the simplest case of plants multiplied by branching root-stocks. From the evolutionary standpoint such differences are of comparatively little moment; all organisms seem to be variable, whatever their methods of reproduction. There is, however, a general law that the more specialized the organism and its reproductive processes the smaller are the probabilities that conjugation can be dispensed with. It is as though complexity of organization required a higher tension of the protoplasmic structure which could not be maintained without conjugation, rest or change. Thus among animals of high organization there are but two conspicuous instances of normal parthenogenesis, the bees and the plant-lice, and in both of these the generations, sexes or castes produced without conjugation are inferior, specialized and unable to maintain the existence of the species. The relative frequency with which parthenogenesis and asexual reproduction are maintained among the lower animals and plants, in connection with parasitic or saprophytic habits suggests the further possibility that protoplasmic compounds of high complexity may be utilized as partial or complete substitutes for conjugation. Cytologists might thus find it worth while to ascertain, if possible, the exact nature of the protoplasmic relations between parasite and host.

fission of Metazoa are adjustments having only an outward resemblance to the budding and fission of Protozoa." While processes, like organisms, must have a common origin if genuine homologies are to be established, it seems obvious that on the plane of Professor Hertwig's discussion conjugation and reproduction are directly comparable throughout organic nature. Current errors are not so much in the direction of mistaking the nature of the processes, as in failing to observe that what is termed 'asexual reproduction' in simple organisms is generally called 'growth' in the more complex. From the cytological standpoint there are two sets of phenomena in both plants and animals, conjugation or fertilization and fission or growth by cell multiplication. The association and specialization of cells in compound organisms (Metazoa and Metaphyta) have given rise to a great variety of independently acquired reproductive adaptations superposed upon conjugation and fission, but different in category, and having neither phylogeny nor homology with those processes.

CHEMICAL AND MECHANICAL THEORIES.

Chemical theory has advanced to the point where different qualities of compounds are explained by reference to positional relations between the component atoms, but behind this lies the question of the nature and qualities of the elemental substances themselves. By common consent the molecular constitution of protoplasm is admitted to be almost unimaginably complex and still utterly inaccessible and intractable from the chemical side. Nevertheless, we recognize that the qualitative or potential differences of protoplasm extend not only to species, but actually to individuals, and yet some biologists are attempting to grasp these ultimate differences before solving the problem of the physical and the chemical groundwork of protoplasmic structure.

A solution of evolutionary problems on this basis can be expected only by those who remain regardless of the fact that the already insurmountable physical and chemical difficulties would be, as it were, multiplied by infinity under theories which imply that not only the complexities of the organic constitution, but also the endless details of individual difference, are symbolized, materialized or predetermined by positional or other relations of atoms, to say nothing of the chromosomes or granules which some have taken to be the actual organs of protoplasmic foreordination. Similar theories invented by theologians

have been set aside by biologists as crudely anthropomorphic. In reality the immediate causes or mechanisms of evolution are as completely unknown as those of the other spontaneous or active properties of protoplasm. Until more light can be shed upon the physical and chemical how and why of assimilation, growth, irritability, motility and reproduction, we can scarcely expect to attain an adequate comprehension of the process which represents a continuous summary of these organic activities.

The center of activity or citadel of the protoplasm of cells is located, evidently, in the nucleus, and there are also reasons for believing that the number, position or other relations of the chromatin bands have important functions in the processes of cell division, and possibly also in determining the relative preponderance of the parental influences. But such facts are very far from proving that either heredity, variation or the resultant evolutionary motion is controlled by purely cytological processes, or that there is any such thing as a 'hereditary mechanism.'* Developed to their logical conclusions, theories of determinants coincide with Nägeli's attempted deduction of the organic universe from the chemical and physical structure of protoplasm, in ignoring the fact that even in the highest organisms cells are still cells, and that from the cytological standpoint they are not improved, but degraded by specialization. A complex organism is more than the component cells, and evolution is not only a cytological, but a social and supercellular process. Life itself is the 'unknown factor,' or neglected cause, which vitiates the theories of those who expect a complete expression of organic phenomena in terms of current conceptions of matter and molecular and atomic forces.

Under cytological or intracellular theories the evolution of unicellular organisms must involve principles fundamentally distinct from those required in multicellular groups, with a similar gap intervening when compound individuals and social units are being dealt with. But if we look upon evolution as a normal property of protoplasm no such complications need be met, higher acquirements being added by gradual superposition. In nature, moreover, there are no breaks in the chain which connects simple and complex types of individuality. Beginning with the absolute individuality of some unicellular organisms where each cell may compete directly with every other cell, we have all grades of association and adhesion; also when the individual compacted of similar and equivalent cells is traced to the point where it begins to manifest increasing differentiation of parts into special tissues and organs. Equally perfect is the series of social adaptations and instincts, through simple aggregations or flocks, to the complex caste differentiations of the highly organized colonies of the social hymenoptera and termites.

A general law of biological evolution must embrace the morphology, physiology, ecology, psychology, ethnology and sociology of the entire organic series, to say nothing of still more general or philosophical applications. But while any process of gradual change and readjustment would bear the teleological interpretation of natural selection, that theory does not furnish an adequate explanation or supply causal connection for the succession of phenomena encountered in any department of biological study.

* The well-known phenomena of asexual reproduction, parthenogenesis and replacement of lost parts should have saved us from theories of localized and mechanical heredity, but if further proof is needed it is now available in the experiments of Loeb in artificial parthenogenesis, those of Delage and others with enucleated fragments of eggs, and those of Mr. A. J. Pieters in growing normal plants from pieces of cotyledons.

COROLLARIES AND CONCLUSIONS.

It will readily be understood that the center of gravity of evolutionary theories will appear to change on admitting the correctness of a kinetic view, and this not only in strictly biological, but in other related lines of thought. Time and space are alike wanting for the canvass of such readjustments; it is possible in the way of summary and conclusion only to notice in a brief and disconnected manner a few of the corollaries and subsidiary theories accommodated or suggested by the belief that evolution is a general property of protoplasm, and not the function of a special mechanism or a reaction to external stimuli.

The differentiation of species is a phenomenon distinct from evolutionary progress; isolation may conduce to the former while retarding the latter.

Selection, acting through isolation, affects evolution by influencing the direction and rate of progress with respect to particular characters; that species may originate through natural selection does not, however, prove that selection is a cause of organic change or of evolution.

Variation furnishes the differentials of which evolution is the integration; selection and isolation may affect the equation either as positive or as negative quantities. Specific differentiation is a direct function of selection and isolation, but evolutionary progress is often an inverse function.

Groups having large, complex and variable species, or numerous closely related species, are in a state of active evolution, while those in which species and genera are few, small and uniform have passed the zenith of their evolutionary history. Thus the compositae and hymenoptera are prosperous, while the cycads and diplopods are on the decline. Primitive characters are to be sought in insular or circumscribed species rather than among related continental or widely distributed types. Static theories would compel contrary inferences.

In large and widely extended species uniformity or diversity of characters depends upon relative facility of distribution; the more rapidly new characters can be disseminated the greater the uniformity of the species. Such uniformity should not, however, be interpreted as stability, which may be relatively greater in locally diversified species.

That diversity is not conditioned upon segregation, but is distinctly favored inside the limits of species, also seems obvious from the differentiations of sex, caste, dimorphism and other similar specializations. Moreover, these phenomena do not represent a single device or adaptation, but have appeared independently in many natural groups.

The relative importance of natural selection has differed greatly in the evolution of the various natural groups; in a general way it may be thought of as proportional to ecological diversity.

Evolution is not a special process or function, but appears in all types of individuals from the unicellular through the various grades of polycellular and compound organisms to the caste-differentiated colonies of the social insects; it accompanies both sexual and asexual methods of reproduction, seedless plants and insects derived from unfertilized eggs continuing to vary and differentiate.

Evolution is both cellular or cytologic and supercellular or organic; the former appears in simple types and in the component cells of higher groups; the latter is a social phenomenon having no obvious or necessary connection with cytological processes.

In some groups it has been ascertained that evolutionary characters or conditions which first appeared in the adult are subsequently passed back into preliminary or

embryonic stages; such facts do not, however, establish a general law of retrogression or recapitulation, since the metamorphoses of insects and other similar phenomena show that evolutionary deviations and adaptations may occur at any stage in the life histories of organisms.

The adaptability of an organism is in general inversely proportional to the degree of ecological specialization already attained. Accordingly, highly specialized types tend to become restricted and to disappear, while the more primitive may persist and give repeated demonstrations of the evolutionary tendencies or variational possibilities of the group.

Parallel evolution is thus not necessarily adaptive or mimetic, and may often be interpreted as an indication that a tendency to a particular variation may outlive specific differentiation and become similarly accentuated, even in groups in which long separation has permitted the accumulation of many differences in other characters.

From the standpoint of a kinetic theory the inheritance of acquired characters becomes a purely formal question; indeed, it may be said that the origination and inheritance of characters are but different statements of the same fact, since characters originate and are extended because of the same inherent tendency to change.

The continued differentiation of vestigial organs and structures shows that there is no essential connection between evolution and use. The vast majority of variations and specific differences are also obviously non useful; they arise, are prepotent and are perpetuated because they are different and new, rather than through any external influence or necessity.

All hereditary characters are acquired, but not all acquired characters are hereditary. There is no reason to believe that any are hereditary which have not been acquired through the assistance of normal variation. Mere mutilations or reactions to external conditions are not hereditary. Evolution is essentially a process of acquiring characters, but no direct nexus between environment and heredity has been demonstrated, and none is necessary under a kinetic theory.

A kinetic theory enables us, in short, to recognize the varied facts of evolution without doing violence to any of them. While holding that all evolutionary changes are essentially the same in having an internal and spontaneous origin, we are still not compelled to deny that adaptations have been influenced by external agencies. Selection represents, however, not the causes, but the external incidents of evolution. Persistent variation should be compared with the main spring, selection to the balance-wheel, of an organic creation which progresses because new characters and powers are welcome, rather than because old types are exterminated.

O. F. COOK.

WASHINGTON, D. C.

THE LATE MILES ROCK.

MILES ROCK, a notable scientist, born at Ephrata, Lancaster county, Pennsylvania, October 10, 1840, died on January 29, 1901, in his sixty-first year.

During boyhood he attended the public schools of Ephrata, and later the Lancaster High School, fitting himself for Franklin and Marshall College. At the outbreak of the Civil War he was pursuing his studies at this college; but love of country and the trend of public spirit at the time prompted him to join the Pennsylvania Volunteers and proceed to the seat of war. He remained a soldier at the front until the close of the war; and it is significant of his character that he carried in his knapsack a copy of Gray's 'Manual of Botany,' and employed his leisure in collecting and analyzing the plants observed in the campaign.

At the close of hostilities he entered Lehigh University, which Asa Packer, the philanthropist of Lehigh Valley, had just founded and established at South Bethlehem; he graduated as Civil Engineer with the first class of Lehigh in 1869. Of the three young men who entered Lehigh in 1866 and formed the first graduating class of this now famous institution of learning, two are gone—J. H. Hind Corbin, and now Miles Rock; the third, C. E. Ronaldson, a mining engineer, of Philadelphia, survives. Mr. Rock's graduating thesis was on 'Forest Trees'; and he treated the theme in physical, moral and scientific aspects, evincing thorough familiarity with the subject, and such originality and breadth of thought as to gain the hearty approbation of his fellow-students, with whom he was highly popular. Immediately after graduation, he became instructor in mineralogy and geology at the University.

In 1870 Mr. Rock married Miss Susan Clarkson, and subsequently accepted a position as astronomical assistant to Dr. B. A. Gould, director of the Cordoba Observatory, Argentine Republic. This he retained until 1873, participating in the Durchmusterung or Zone work, undertaken by Dr. Gould, and in mapping the multitude of star observations of the southern heavens. The results of his astronomical work at Cordoba are embodied in 'Uranometria Argentina,' published in Buenos Ayres in 1879.

In the autumn of 1874, Mr. Rock cooperated with Commander F. M. Green, of the U. S. Navy, in determining latitudes and longitudes, by means of submarine cables, in the West Indies and Central America, for the use of the Hydrographic Office. He was occupied in this work until 1877. During the two years immediately following he served as a field astronomer in the U. S. Geographical and Geological Surveys west of the 100th meridian under Lieutenant George M. Wheeler, of the U. S. Engineers, and determined latitudes and telegraphic longitudes in several of the western states and territories. On July 1, 1880, he was appointed assistant astronomer at the U. S. Naval Observatory, and served acceptably in that capacity at the transit circle under the immediate direction of Professor John R. Eastman, U. S. Navy. In 1882 he was detailed to aid Professor Lewis Boss in the observation of the transit of Venus at Santiago de Chile in December of the same year.

On the recommendation of the U. S. Government, Mr. Rock was appointed astronomical engineer for Guatemala in 1883; and for fifteen years he served as Chief of the Guatemala Boundary Commission, charged with the duty of determining and locating the disputed frontier between Guatemala and Mexico. To his technical knowledge, diplomatic skill, strong sense of justice, and invincible courage, Guatemala unquestionably owes the retention of her rights in certain valuable lands in the district of Peten, which had been claimed by Mexico, even to the point of threatened hostilities.

As a Commissioner Mr. Rock was highly regarded by the Guatemalan authorities, especially as he seldom failed to evince a ready and deep interest in the people, and in the development of the resources of the republic. During his incumbency he also served as the delegate of the Guatemalan Government to the International Congress at Washington in October, 1894, which adopted for the nations represented the uniform zero-meridian of Greenwich for maritime purposes.

On the completion of his official work for the Guatemalan Government, in 1898, Mr. Rock remained in the country, devoting himself to private interests.

Mr. Rock never ceased to take a keen interest in the affairs of his *alma mater;*

and on the formation of a Lehigh alumni association at Philadelphia in 1870 he was chosen its first president, and a few years later was appointed an honorary alumni trustee. He last visited Lehigh on the occasion of a reunion of the alumni in 1897, when he delivered an address. He was a frequent contributor to the collections of the several scientific departments of the University, and many of his collections are preserved in the University Museum. A nominal resident of, and frequent visitor to, Washington, he took a prominent part in the scientific activities of the Capital. He was one of the founders of the Anthropological Society of Washington, and of the Cosmos Club; he was also a member of the Washington Academy of Sciences and of the National Geographic Society.

Mr. Rock's death was sudden, resulting from acute gastritis followed by heart failure. The sad intelligence was reported to the State Department on the second of last February, by United States Consul-General McNally of Guatemala.

In recognition of the great worth of the services which Mr. Rock had rendered to Guatemala during the years of his official activities there, the Government of that country took charge of the funeral; and he was buried in the cemetery of Guatemala City with public honors under the personal direction of President Cabrera. In their official reports to the Department of State, the representatives of this country in Guatemala showed that Mr. Rock was universally mourned, and that no such funeral honors had ever before been accorded to anyone but the highest officials of the country. The most affecting if not the most impressive feature was the attendance of hundreds of poor natives, who had known Mr. Rock and experienced his never-failing kindness and generosity, who silently and tearfully followed him to his last resting place. Simple in their own lives and thoughts, they paid the only tribute at their command to the man whose singleness of purpose, love of justice and warmth of heart endeared him to all who knew him. Peace be to his ashes!

Mr. Rock leaves a widow, a married daughter, Mrs. F. L. Ransome, and a son, Alfred Mayer Rock, all of whom reside in this city.

William Eimbeck.

Washington, D. C.,
April 22, 1901.

OTTO LUGGER.

Otto Lugger, State Entomologist of Minnesota, who died May 21, from pneumonia, after a very short illness, was one of the most widely known of the many Americans of German birth who have obtained high scientific reputation in this country. He was born at Hagen, Westphalia, September 16, 1844. His father was a professor of chemistry in a Prussian university. Lugger was educated in Hagen, and in 1864 became a lieutenant of cavalry in the Prussian army. In 1865 he came with his parents to the United States and secured a position with the engineer corps of the army, and for two years was engaged in the survey of the Great Lakes. He had always been interested in entomology, and collected specimens while engaged in his engineering work. He became acquainted with the late C. V. Riley, who at that time was occupied in newspaper work in Chicago, and, when in 1868 Riley was appointed State Entomologist of Missouri, Lugger went with him as his assistant. During the years 1868 to 1875, when Riley established his great reputation as economic entomologist and published eight of the nine annual reports which brought him lasting fame, Lugger remained his quiet, unassuming, self-sacrificing and devoted helper. In 1875 he married Lina Krokmann and went to Baltimore, where he became the curator of the

Maryland Academy of Sciences and naturalist of the city parks. In 1885 he was appointed assistant in the Division of Entomology of the U. S. Department of Agriculture, remaining in Washington until 1888, when he was appointed entomologist to the State Agricultural Experiment Station of Minnesota, publishing his first bulletin in this new office July 3, 1888.

His first entomological experience in the State of Minnesota was one of great interest and importance, and his vigorous and intelligent action in the face of a great emergency fixed his standing as a most useful officer firmly in the minds of the Minnesota farmers. An enormous swarm of the Rocky Mountain locust or western migratory grasshopper had settled down in Ottertail County. By Lugger's advice and energetic field work, backed as he was by a public-spirited and intelligent governor (Hon. W. R. Merriam, now director of the U. S. Census) who personally guaranteed the funds necessary for the campaign, the hordes of destructive insects were annihilated and great damage was averted.

From that time to the time of his death, nearly thirteen years, Lugger's work was most active; his publications were frequent, and he gained the profound respect of his constituents and of the scientific men of the country. His bibliography, covering about thirty titles of record, comprises almost exclusively articles on economic entomology, but he was by no means a one-sided naturalist. He was a good botanist and published several papers concerning plant diseases, notably his article on the black rust or summer rust (Bulletin 64, Univ. Minn. Agric. Exp. Station).

Some years ago he began the publication of a series of large papers which when brought together would have formed an elaborate treatise on the entomology of Minnesota. The parts which had been published were an extensive paper on the parasites of man and domestic animals (Bul. 48, 1896, Minn. Agric. Exp. Sta., pp. 72–270, figs. 187, plates 16), the Orthoptera of Minnesota (Bul. 55, 1897, pp. 91–386, figs. 187), the Lepidoptera of Minnesota (Bul. 61, 1898, pp. 55–334, figs. 237, plates 24), the Coleoptera of Minnesota (Bul. 66, 1899, pp. 85–331, figs. 249, plates 6), and the Hemiptera of Minnesota (Bul. 69, 1900, pp. 1–259, figs. 200, plates 15). It is a great pity that Lugger did not live to complete this series, since the elaborate numbers were profusely illustrated and were prepared with great care and written in a most interesting style. At the time of his death he was preparing the part on Diptera, in which he intended possibly to include the Neuropteroids. It is greatly to be hoped that his manuscript was sufficiently advanced to permit its publication.

Aside from his scientific ability, Lugger was a man of admirable qualities. His wide information, his agreeable personality and his keen sense of humor made him one of the most delightful companions I have ever known. Many of his stories and humorous sayings are current among entomologists all over the United States, and his loss will be felt for many years to come. He leaves a widow and two children—a daughter, Mrs. Linnea Clarke, and a son, Humboldt Lugger, the latter now living in Kentucky.

L. O. HOWARD.

SCIENTIFIC BOOKS.

The Phytogeography of Nebraska. I. General Survey. 2d Ed. ROSCOE POUND and FREDK. E. CLEMENTS. Published by the Botanical Seminar, University of Nebraska, Lincoln, Neb. 1900. 8vo. Cloth. Pp. 442 and 4 maps.

To those who have not paid special attention to this branch of investigation this volume will prove to be both a revelation and an incentive to learn. It is a revision of the first edition, issued some three years ago, with additional material

acquired since that time, the larger part of the first edition having been destroyed by fire in the building of the publishers.

In its broadest conception the subject is happily defined as 'the study of vegetation,' or in other words, the study of the floral covering of any area in the aggregate. It deals with the plant groups rather than with individuals, and with the interrelations of species rather than with the species themselves, and discusses the reasons why certain plants have become established in certain areas, the effects of environment, etc.

The treatment of the subject begins with an historical review of the investigations which have been made in the flora of Nebraska, commencing with the expedition of Lewis and Clarke during the years 1803–1806, and continues through what may be called the era of exploration, to about 1870, up to which time the study of botany was merely incidental, in connection with general surveys and explorations. Botany as a distinct subject of investigation did not receive attention until 1871, and it was not until 1884 that it was prosecuted in earnest, under the direction of Dr. C. E. Bessey, who was elected to the then newly created chair of botany in the University of Nebraska. The botanical seminar of the University was organized, and for the first time a systematic investigation of the flora of the State was begun.

The preliminary work of cataloging the flora of the state was accomplished and then was commenced the study of the vegetation as a whole, in connection with topography, geology, meteorology, etc.

Four phytogeographical 'regions' are recognized, as follows:

I. Wooded-bluff and Meadow-land.
II. Prairie.
III. Sandhill.
IV. Foothill.

Regional limits, within a relatively small and artifically limited area such as the State of Nebraska, are primarily dependent upon physiography. Vegetation 'zones' and 'realms' are only applicable to more extended areas, with natural boundaries based on geographic or climatic conditions.

Following the system of Drude, the phytogeographic regions of Nebraska would all be included within the Middle North American Realm of the Northern Zone, and by a division of this realm into 'provinces' (Allegheny, Prairie, Rocky Mountain, Great Basin and California) the greater portion of the State would fall within the second of these, with a small strip along the eastern edge representing the first.

Lists of species peculiar to each region, those that are common to two of the regions, and those that are common to three or more of the regions, are given. The distribution of any species, or in other words the area over which it occurs, is of course a mere matter of more or less careful observation, but the abundance of a species can only be determined by careful investigation and calculation, the method of which is described, together with the formulæ adopted.

The terms employed are somewhat bewildering in their number and the fineness of their distinctions, and doubtless many who are not directly interested in the subject may become impatient at the necessity for mastering the differences between 'abundant,' 'frequent,' 'sub-frequent,' 'infrequent,' 'sparse,' 'rare,' 'solitary,' 'copious,' 'gregarious,' 'gregario-copious,' etc.

In the division of the plants into 'vegetation-forms' will be found another series of terms, popular and scientific, such as woody plants ('trees,' 'shrubs,' 'under-shrubs,' 'climbers and twiners'), half-shrubs, herbs ('rosettes,' 'mats,' 'succulents,' 'sod-formers,' 'rootstock-plants,' etc.), water plants ('floating,' 'submerged' and 'amphibian'), saprophytes, parasites, mosses, fungi, algæ, etc., with discussion of habitat, foliage, protective devices, period of flowering, methods of dissemination, etc.

The factors concerned in the phenomena of phyto-geography are both physical and biological. They are connected with environment (topography, temperature, moisture, mechanical and chemical composition of the soil, etc.), and with the influence of animals, including man, as well as with the influence of plants upon each other, and each natural group of plants may be affected differently by the same factor or factors. In this connection each natural group is discussed in sequence.

The final part of the work deals with what is denominated 'plant formations,' and a plant formation is defined as 'a piece of the floral covering, the extent of which is determined by a characteristic correlation or association of vegetable organisms, *i. e.*, it is a stretch of land the limits of which are biological and not physiographical.' They may or may not, therefore, be coextensive with the regional distribution of the plants which compose them.

With respect to their origin they may be either primitive or recent. Primitive origin is necessarily more or less conjectural. It involves the study of the extinct flora of the region and the geologic changes which finally led up to the establishment of existing conditions. Recent formations may arise either from nascence or by modification. If by nascence they must originate upon areas previously destitute of any floral covering, while in the second case they are formed by the elaboration or modification of existing formations, often by the intrusion of foreign elements. Abandoned cultivated patches may represent the first, timber claims the second. Formations often disappear through the agency of fires, floods, mankind, etc., in which cases new formations may arise by nascence.

As an example of the latter is quoted the establishment of *Botrydium granulatum* or *Vaucheria sessilis*, with the cup fungi *Humaria* and *Scutellinia*, on muddy flats, formerly occupied by water plants, but subsequently exposed by the drying up of ponds or streams. A carpet-like layer may then supervene, composed of *Riccia glauca*, *Funaria hygrometrica*, etc., which in turn may be replaced by low-growing flowering plants, such as *Portulacca oleracea*, *Lepidium intermedium*, etc., and this in turn may yield to taller growing *Chenopodiums*, *Amaranths*, etc.

In the origination of formations by modification two sets of factors may be distinguished—natural and artificial. The first are either biological or physical, the second are due to the influence of man or other animals. An unusually wet season in the sandhill region or a dry one in the lowland will often modify the floral covering in a striking way, and modification through the agency of man is too obvious to require more than passing mention.

The various plant formations recognized are finally considered in detail and discussed under headings and sub-headings, physiographical and biological. For example, under the forest formations may be found the river-bluff formation, including (1) the red oak-hickory formation, (2) the bur oak-elm-walnut formation, etc.; under prairie formations, (1) prairie grass, (2) buffalo grass; under foothill formations, (1) under-shrub, (2) mat and rosette, (3) grass, etc., and many others.

The work as a whole is exceedingly valuable for the wealth of facts recorded, irrespective of any conclusions which may be deduced from them, and no one can fail to appreciate the immense amount of conscientious labor which it shows.

ARTHUR HOLLICK.

Synopsis of the Naiades, or Pearly Fresh-water Mussels. By C. T. SIMPSON. Proc. U. S. National Museum, XXII. 1900. Pp. 501–1044.

Some people think that the preparation of zoological catalogues and synopses is a low grade of work, which should be turned over to those who are not capable of doing anything better. Certainly one occasionally meets with examples of zoological bibliography bad enough to have been compiled by the most incompetent, but it is to be remarked that the authors of these works are often really skilled in anatomy or some other branch of the science. The fact is that the preparation of such a work as we have before us, with its orderly arrangement of innumerable references, requires not merely a high grade of intelligence, but a special kind of ability, which is none too common. We may therefore begin by thanking Mr. Simpson for a work which no other living man was equally competent to produce, and which will be invaluable to all students of the naiades. But to regard the work as merely a piece of good bibliography, would be extremely erroneous. Mr. Simpson has carefully studied a considerable majority of the species, and the arrangement of them is original with him. He has, by an examination of the soft anatomy, been able to show that the genus *Unio* of authors is in reality a heterogeneous mass of distinct genera, which

he duly describes. In all, 72 genera are recognized, of which 25 were first named by Mr. Simpson, while many others, credited to various authors, were first properly defined by the same writer. All this amounts to a revolution in naiadology, comparable with that produced by Pilsbry in the study of the Helicidæ.

Of interest to general biologists will be the map given showing the distribution of the naiades. In the Old World the regions of Sclater and Wallace are respected by the freshwater mussels, except that New Guinea goes with the Oriental region, as also do Japan, Corea and Manchuria. In America the neotropical region is valid for naiades, but North America is divided into three primary regions, the Atlantic, the Mississippi and the Pacific, but the last is considered a part of the Palearctic! In all about 1,117 species are recognized, many having long lists of synonyms. Concerning the innumerable so-called species described from France by the followers of Bourguignat, Mr. Simpson says: "Life is too short and valuable to be wasted in any attempt at deciphering such nonsense, and I have not even cumbered the pages of this work with a list of these new species." It is indeed unfortunate that the interesting character of the European fauna should be obscured by the treatment it has received at the hands of its students. The freshwater mollusca, in particular, exhibit a wonderful polymorphism, which in the highest degree merits the attention of the evolutionist; but when every varying phase is designated a species the result is mere chaos. When I lived in England, I knew of a number of ponds producing special forms of *Limnæa* (particularly *L. stagnalis*), which were so different that they could be recognized at a glance; one of the most distinct of these varieties abounded in a pond no bigger than a large rug, and was found nowhere else. The same sort of thing is true of the European naiades, and a careful comparative study of all the forms called species by the Bourguignat school, with an account of the several conditions under which they exist, would be an extremely valuable contribution to biology.

As is inevitable in so great a work, a few errors of nomenclature occur. The new genus *Dromus* will be considered by some too similar in name to *Dromius*, Bon., but I think it should be allowed to stand. The genus *Nodularia* Conrad, 1853, is preoccupied by *Nodularia* Oken, 1815. This will apparently oblige us to call the genus *Lanceolaria* Conrad, with *Lanceolaria grayana* (Lea) as the type, while the section of *L. douglasiæ* (Gray) can be called *Nodularidia* n.n. On p. 851, *Ptychorhynchus incertus* should be *P. murinus* (Heude), and on p. 897, *Spatha tristis* should be *S. rochebrunei* Jousseaume.

T. D. A. Cockerell.

East Las Vegas, N. M., May 12, 1901.

SCIENTIFIC JOURNALS AND ARTICLES.

The leading article of the *Botanical Gazette* for May is the 'Genetic Development of Forests of Northern Michigan, a study in Physiographic Ecology,' by H. N. Whitford. The factors that influence tree growth are divided into three groups—climatic, ecologic and historical. Favorable climatic factors make possible a forest formation; ecologic factors bring about the plant society condition; and the historical factors, by changing the physiographic features, change the plant societies. The life histories of five series of plant societies are discussed, *viz.*, sand, clay, rock, swamp and clearing societies. In four cases there is a gradual progression from xerophytic societies to a mesophytic forest. In the case of the swamp the progress is from hydrophytic societies to a mesophytic forest. The article is illustrated with eighteen half-tone reproductions of photographs. E. W. D. Holway contributes his third paper on 'Mexican Fungi,' in connection with Dr. Dietel, describing thirty-one new species of Uredineæ. Mr. G. M. Holferty gives the results of his study of the ovule and embryo of *Potamogeton natans*, clearing up a number of gaps in our knowledge of this primitive monocotyledonous type. The paper is illustrated by two excellent plates. Mr. Charles T. Druery, of London, writes upon 'Fern Variation in Great Britain,' and calls the attention of American students to the great scientific value of looking after fern 'sports.' Mr. D. G. Fairchild, agricultural explorer of the U. S. De-

partment of Agriculture, contributes his fourth 'Notes of Travels,' dealing with 'Coffee growing in Brazil and the giant Jequitibá trees.' The usual Book Reviews, Minor Notices, Notes for Students, Open Letters, and News Items close the number.

Terrestrial Magnetism and Atmospheric Electricity for May contains the following articles:

'Summary of the Results of Recent Investigations in Atmospheric Electricity' (Concluded): F. EXNER.

'The Physical Decomposition of the Earth's Permanent Magnetic Field—No II.'; 'The Composition and Characteristics of the Uniform Magnetic Field': L. A. BAUER.

'Résumé of Magnetic Work at Bombay Observatory in 1897.'

'The Magnetic Work of the Norwegian North Polar Expedition, 1893–1896': D. L. HAZARD.

'Summary of Results of Recent Comparisons of Magnetic Instruments': L. A. BAUER.

'Schuster's Researches on the Solar Rotation and the Lunar Period in the Earth's Magnetism.'

'Biographical Sketch of William Ellis' (with portrait).

THE number of *Popular Astronomy* for the months of June and July has for its frontispiece the orbit of the new comet discovered by Halls, of Cape Colony; the elements and ephemeris as computed by Dr. Kreutz accompanies a brief article upon the comet. Among the other short articles is one by E. C. Pickering on the 'Variability of Light of Eros.' From the *British Journal of Photography* there is reprinted an article on the scientific value of photography for astronomical investigations. The recent eclipse is still too near us to have obtained full knowledge of the results, but a discussion of 'What Eclipses Teach Us,' comes from the pen of David P. Todd, who went out with the Amherst party to Sumatra. Miss Mary Clark Traylor gives an explanation of the method of computing an ephemeris of a planet or comet, of interest to the amateur astronomer. Spectroscopic notes, planet notes and the usual planet tables are included in the number.

THE Museums Association of Great Britain will commence in July the publication of a monthly journal devoted to the interests of museums in general. Besides the proceedings of the Museums Association it will contain current news of museums and art galleries, illustrated descriptive articles, reports of museums, reviews of books and brief notes. Mr. F. A. Lucas, of the U. S. National Museum, will act as the American correspondent of the journal, and he will be glad to receive any articles, no matter how brief, pertaining to the work of museums in the United States, or they may be sent directly to the editor, Mr. E. Howarth, of the Sheffield Museum, England.

SOCIETIES AND ACADEMIES.

PHILOSOPHICAL SOCIETY OF WASHINGTON.

THE 536th regular meeting was held May 11, 1901. The special order of business was to consider the question of incorporating the Society under the general laws of the United States for the District of Columbia. After discussion it was unanimously

Resolved, That the Philosophical Society adopt the recommendation of the General Committee to incorporate the Philosophical Society of Washington, and that the carrying into effect of the foregoing resolution be entrusted to the General Committee.

The 537th meeting was held May 25, 1901. The Chairman, V. P. Rathbun, stated that pursuant to the instructions of the Society at the last meeting the General Committee had filed Articles of Incorporation on May 20, 1901, said Articles being signed by three of the founders of the Society and 23 past presidents and other officers of the Society. He also stated that at a meeting of the incorporators just held all the members of the Society had been elected to the incorporated society.

A code of by-laws was adopted, and the former officers were elected to corresponding positions in the new Society.

President Walcott then took the chair. In response to a question, and after discussion, he ruled that the organization was to be continuous, and that the present meeting did not begin a new series.

The first regular paper was by Dr. G. M. Sternberg on the 'Transmission of Yellow Fever by Mosquitoes.' (This paper will appear in *The Popular Science Monthly.*)

Mr. J. W. Froley then described some 'Appliances for describing Oval and Circular Arcs of very large radius.' The principal one depended on the fact that a uniform elastic bar, bent by equal oppositely directed forces takes the form of a circular arc. The presentation was too mathematical to be condensed here.

The Society then adjourned till October.

CHARLES K. WEAD,
Secretary.

TORREY BOTANICAL CLUB.

AT the meeting of April 9, 1901, the scientific program consisted of a 'Report on a Recent Visit to the Royal Gardens at Kew, England,' by Mr. George V. Nash. Mr. Nash was absent about six weeks, nearly the entire time on the other side being spent at the Royal Gardens, Kew, securing specimens of living plants for the New York Botanical Garden. The collections were carefully inspected under the guidance of the officers of the institution, and such duplicate material picked out as was desired. In this way much valuable material was secured, both for the outside and conservatory collections. Many of these were procurable only at a botanical garden, and a number of them were not obtainable elsewhere than at Kew. Of the large number of plants selected, over 1,000 species have already been received and incorporated in our collections. These include about 550 species of herbaceous plants, 350 shrubs and trees, and 150 succulents. The remainder of the material will follow as fast as the authorities at Kew can select it.

Dr. Britton remarked that the favor accorded by Sir William Dyer in permitting Mr. Nash to select duplicates of living plants from the rich collections at Kew would be most gratefully appreciated not alone by the managers and members of the New York Botanical Garden, but by all American botanists.

Dr. Britton presented a communication on a tree new to the American continent, a white birch from the Alaska region, collected by Mr. R. S. Williams and Mr. Tarleton and represented in the U. S. National Herbarium also by two specimens collected by Miss E. Taylor.

At the meeting of April 24th a paper by Professor Francis E. Lloyd, entitled, 'The Genus *Lycopodium*: A Criticism,' in the absence of the author, was read by the secretary pro tem. This was a review and criticism of the treatment of the genus *Lycopodium* by Pritzel in the recently published part of Engler and Prantl's 'Die natürlichen Pflanzenfamilien' dealing with the Lycopodiaceae. The paper will be published in full in an early number of *Torreya.*

Professor Underwood remarked on segregations in the *Selaginella rupestris* group, stating that Dr. Hieronymus, of Berlin, had recently recognized twenty-seven species in this group, some of them American, outside of those recently proposed in this country.

MARSHALL A. HOWE,
Secretary pro tem.

THE ACADEMY OF SCIENCE OF ST. LOUIS.

AT the meeting of May 20, twenty-six persons present, Professor George Lefevre presented a comprehensive address on the advance made in the science of zoology during the nineteenth century.

Professor F. E. Nipher presented a paper determining the specific heat of a nebula, in process of gravitational contraction. It is found to be equal to the constant for the gas, provided by the mechanical equivalent of heat. This is also equal to the difference between the specific heats, at constant pressure and at constant volume. The relation between pressure and volume of the gaseous mass during contraction is determined in terms of the fundamental constants, the gravitation constant, the constant of the gas and the mass of the contracting nebula. In the same way, the relation of pressure to temperature and of volume to temperature are determined. It is a matter of profound significance that a cosmical gaseous mass can apparently pull itself together, and at the same time become warmer, as it might if compressed by some external force. It raises the question whether the mass does really contract itself when it gravitates into a smaller volume, or is gravitation, after all, a force acting from without and upon the two bodies which seem to attract each other ?

One person was elected to active membership.

WILLIAM TRELEASE,
Recording Secretary.

DISCUSSION AND CORRESPONDENCE.

REMARKABLE DISCOVERIES.

IN *McClure's Magazine* for June there appears an article, entitled 'Geology and the Deluge: Remarkable Geological Discoveries in Central Asia and Southern Russia, showing that the Noachian Flood is a Scientific Possibility,' by Dr. Frederick G. Wright, Professor of the Harmony of Science and Revelation in Oberlin College.

The first of these 'discoveries' is entitled 'No Glacial Period in Asia.' It is set forth in the following words:

"For many years I have been collecting facts concerning the glacial period in North America and Europe, and in 1900 I went to Siberia to determine conditions in that country in the same period. As Asia, like North America, stretches toward the North Pole and faces a great sea on the east, I naturally expected to find there evidences of a glacial period similar to that in this country. But, contrary to all my expectations, I found no sign in Central Asia and Southern Siberia of glacial work. On the contrary, the geological conditions I found were such as are only to be explained by an extensive submergence of the region where the Scriptures and tradition locate the Flood which destroyed the whole human race, excepting Noah and his family. The evidences of such a deluge are not one, but several, and extend from Mongolia to the western borders of Russia."

The state of previous knowledge may be inferred from the following quotations from well-known works, to which others might be added:

"It is a familiar fact that there are no traces of glaciation in Northern Asia, but on the contrary there is the most complete and consistent evidence that no such traces are to be found either on the flat tundras or on the higher ground. Murchison long ago showed that there are no marks of ancient glaciation on the Urals, which it must be remembered rise in places to a height of 1,525 metres, and are in many places covered with snow for eight months in the year. Repeated visitors have tried in vain to find old glacial traces in the Altai Mountains. Lastly, traveller after traveller across Northern Asia speaks of the absence of all boulders, rounded rocks, etc., in Siberia from one end to the other." ['The Glacial Nightmare and the Flood,' by Sir Henry Howorth, Vol. I., pp. 510, 511, 1893.]

"These [certain mountainous and plateau tracts], as far as I can learn, are the only regions in Asia which have yielded certain traces of glaciation. (See Plate XIV.)" [The plate shows no general glaciation in Siberia or Central Asia.] ('The Great Ice Age,' by James Geikie, third edition, p. 697, 1894.)

"East of the Urals in Northern Asia there is no evidence of moving ice upon the land during the Glacial period." ('Man and the Glacial Period,' by G. Frederick Wright, p. 190, 1892.)

The second 'discovery' relates to the general prevalence of loess in the region named. This is set forth as follows:

"*Evidences of a great sea around Mt. Ararat.*—On the contrary, throughout this entire region we were confronted with the evidence of a great subsidence of the land which had taken place in recent geological time, and which, in date, would correspond roughly with that of the glacial period in North America. For several hundred miles, while driving through the region south of Lake Balkash and the Aral Sea, we were evidently upon a terrace of the fine loam which is called loess, about 2,500 feet above sea-level. Indeed, at different elevations this loess extends continuously in a broad shelf along the base of the mountains, from the Irtish River to the Caspian Sea, and is found in extensive areas over various portions of the Caucasus and Northern Persia around the base of Mount Ararat; while the so-called 'black earth' of Southern Russia is a deposit of the same material, and probably of the same age, 100 or more feet in thickness. The distribution of this loess is the key to the whole situation" (p. 135). [The map accompanying the article 'showing the country through which Dr. Wright traveled, and where he found evidences, not of glaciers, but of a flood,' and on which the itinerary is marked, indicates that Dr. Wright did not visit Mt. Ararat or the Biblical lands.]

The degree of originality of this 'discovery' of the distribution of the loess may be inferred

from the following quotation from Geikie's 'Ice Age' in the chapter on Asia:

"Immense sheets and terraces of loess fringe the alpine lands and sweep outwards upon the low grounds of Turkestan and Siberia, but do not seem to go much farther north than 54° N. L. These, as Kropotkin shows, present the same character as the similar accumulations of Europe, and have yielded remains of mammoth, rhinoceros, etc., and land shells. In Northern China the same accumulation is developed on a yet grander scale—covering enormous areas, and occurring at all altitudes from a few feet to upwards of 8,000 feet above the sea. The distribution of the Asiatic loess, its general character, and the nature of its organic remains hardly allow us to doubt that it has been formed under the same conditions as the similar deposits in Europe. Its materials, we may believe, are largely of fluvio-glacial origin, and represent in great measure the flood-loams swept down from the mountains and plateaus when these supported extensive snow fields and glaciers. But, as Baron Richthofen in his great work on China has demonstrated, the loess, as we now see it, owes its structure and heaping-up to the action of the wind, and is even now forming and accumulating in many regions of Asia. It is, in short, a true steppe formation." (Geikie's 'Great Ice Age,' p. 699.)

In discussing the origin of the loess, Dr. Wright omits all direct reference to the familiar interpretation sketched by Geikie and held by many geologists on both continents, and thus adroitly creates the impression that the question of its deposition lies solely between the work of the wind and the work of the sea. The following extract embraces the essential part of the statement:

"Twenty-five or thirty years ago Baron Richthofen endeavored to make out that the loess was a wind deposit; and certainly he found much in Northeastern China to support this theory. Upon returning from our trip to the Mongolian frontier, we were inclined to accept it, for we had seen and experienced, in the dust-storms encountered, enough to make us attribute almost anything to the power of wind. For a whole day we once rode in a cloud of dust so dense that it was impossible to see objects twenty feet away; while everywhere in the mountain valleys we saw instances where this loess had drifted into protected places, as snow does in winter. But there were constantly appearing other things which were difficult to explain by the action of wind. For example, the loess was occasionally spread out, even at high levels, in broad, lakelike basins, as if deposited by water. Also the material now most blown about by the wind is coarse sand, which is piled up in dunes quite unlike the ordinary loess deposits. In one instance we found high walls of a large Chinese city completely buried on one side by a wind deposit; but this was coarse sand, and not loess. In many cases, also, we found long lines of gravel and pebbles interstratified with loess. Thus the difficulties of explaining everything by wind so increased that they became well-nigh insuperable.

"But, on coming around to the northwestern side of the great Asiatic plateau, in Turkestan, which is almost the exact center of the continent, the wind hypothesis became entirely incredible, and the evidence accumulated that the land had lately been depressed to such an extent that the water of the ocean reached the base of the bordering mountains, rising to a height, certainly, of about 3,000 feet; for, at this level, south and southwest of Lake Balkash, we found the loess spread out in such an extensive terrace that the wind would be entirely incompetent to produce the results. * *

"In confirmation of this theory of a recent extensive depression of Central Asia, a number of other most interesting facts present themselves, prominent among which are those concerning Lake Baikal. * * * A most curious fact, long known to scientific men, is that this lake is occupied by a species of seal almost identical with those found in the Arctic Ocean. The same species with slight variations are also found in the Caspian Sea, but not anywhere else along the 3,000 or 4,000 miles which separate these bodies of water. The most probable explanation of this fact, and the one usually accepted by scientific men, is, that these species of seal were thus widely distributed during a continental subsidence in which all the waters of the Arctic Ocean

covered all of Northwestern Siberia, and extended up to the base of the great Asiatic plateau which we followed for such a long distance on elevated shore lines in Turkestan. When this depressed area emerged from the sea, it left the seal isolated in the two great bodies of water which still remain on its former margin. So lately has this taken place, that there has not been time for any great changes to be effected in the characteristics of these animals" (p. 136).

Certain high-level deposits at Trebizond and Dariel Pass are cited as the work of the sea and as evidence of subsidence of the land, but no fossils are mentioned (p. 137).

Singularly enough, the comparative *freshness* of the waters of the Caspian and Aral seas made the basis for the inference that "this region has lately emerged from below sea level and, in consequence, rapidly passed through climatic changes which have transformed it from a recently well-watered region to one that is now a desert" (p. 137).

This is the entire evidence upon which the marine origin of the loess is postulated. The direct evidence of the fossil content of the loess is ignored. The public are not even informed of the existence of this class of evidence, nor of such widely current deductions from it as those voiced by Dr. James Geikie in the paragraph previously quoted and by Sir Archibald Geikie in the following extract from his well-known 'Text-Book':

"Though on the whole not rich in fossils, the loess has yielded a peculiar fauna, which singularly confirms Richthofen's view that the deposit was a subaerial one. In the first place, the shells found in it are almost without exception of terrestrial species. * * * It is worthy of note that *Helices* and *Succineas* abound at present in the steppe regions of central Asia, and that many of the species of loess mollusks are now living in east Russia, southwest Siberia, and on the prairies of the Little Missouri in North America.

"From various parts of the European loess, Dr. Nehring has described a remarkable assemblage of animals, which included a jerboa (*Alactaga jaculus*), marmots (*Spermophilus*, several species), *Arctomys bobac*, tailless hare (*Lagomys pusillus*), numerous species of *Arvicola*, *Cricetus frumentarius*, *C. phœus*, porcupine (*Hystrix hirsutirostris*), wild horses, and antelopes (*Antilope saiga*). This fauna, excepting some extinct or extirpated species, is identical with that which now lives in the southeast European and southwest Siberian steppes. Besides these distinctively steppe animals the loess contains numerous remains of the mammoth and woolly rhinoceros, likewise bones of the musk-sheep, hare, wolf, stoat, etc. It has also yielded flint implements of Palæolithic types. The bones of man himself were claimed many years ago by Ami Boué to have been found in the loess, and his opinion has been in some measure strengthened by more recent observations." ('Text-Book of Geology,' by Archibald Geikie, pp. 1059, 1060.)

The readers of *McClure's Magazine* are not invited to consider the overwhelming force of this class of evidence; nor are they frankly told of the absence of marine fossils from the loess; nor are they informed that the association of Palæolithic implements with the loess is familiar text-book knowledge; but in lieu of such prosy science, they are inspired by the following eloquent climax:

"The crowning point of interest is reached in the discovery by Professor Armashevsky at Kief of flint implements and burnt stones in connection with the bones of extinct animals fifty-seven feet below the undisturbed surface of this soil. The discovery was made in the bluff of loess bordering the river Dnieper, whose general surface is 633 feet above the sea and 340 feet above the present stream, and totally unconnected with any deposits that may have been made by it. In this discovery we have the link connecting the recent geological changes in the East with those in the West. The flint implements of glacial man found in France, England, and the United States indicate the same stage of culture as that attained by the men who were overwhelmed in the great subsidence of Central Asia and Southeastern Russia, and of the region about the base of Mt. Ararat" (p. 138).

This remarkable article closes with 'The Relation of These Discoveries to the Bible Story of the Deluge,' and 'Harmony of Biblical Story and the Geological Facts.'

"* * * What the recent discoveries have shown is, that during, and subsequent to, the glacial period, and since the advent of man, there has existed such an instability of the earth's crust that the present cannot be made a measure of the past. Man has certainly witnessed catastrophes by flood which are quite analogous to the one described in Genesis. But it is important, in conclusion, to obtain correct ideas of what we are required by the narrative to believe. * * *

"1. The biblical account of the flood does not imply, as many seem to assume, that the waters of the earth increased to such a degree that it swelled the circumference of the globe to the extent of the tops of the highest mountains. * * * (p. 138.)

"2. Nor is it necessary, except for the purpose of effecting the destruction of the human race, to suppose that the flood was, in the strict sense of the word, universal. We may well believe that the end in view, namely, the destruction of the human race, with the exception of Noah and his family, was accomplished without the destruction of all forms of animal life whose existence was unconnected with the general moral reasons for the flood. * * * The objects of the flood were all satisfied if the destruction of the human race was fully accomplished, so that history could make a new start with a selected family. * * * (p. 138.)

"Some time during the prevalence of glacial ice over Northern America and Northwestern Europe, man came into existence in Central Asia, where the climate was still congenial. From this point he spread as far west as the Atlantic seaboard in Europe, and eastward to the Pacific Coast, whence he succeeded in reaching, by way of the Bering Sea and Alaska, the western coast of North America, and thence migrated to the Atlantic Coast, where his remains are found in the glacial gravels of Trenton, New Jersey. But the extreme and rapid changes incident to the closing stages of the glacial period naturally, and very likely, exterminated man in company with many of the animals accompanying him both in America and in Europe. The destruction of many of the species of animals accompanying man at the close of the glacial period is a well-known fact. It also seems probable, from scientific evidence, that man shared largely in the destruction. There is everywhere a sharp line of distinction between Palæolithic and Neolithic man, *i. e.*, between the men who were limited to the use of flaked or rough stone implements and those who used smoothed stone implements. It is Palæolithic implements only which are found in the glacial gravels of America and Northwestern Europe, and beneath the loess at Kief and at three or four other localities in Southern Russia. The Palæolithic man of science may well be the antedeluvian man of Genesis" (p. 139).

From this it appears, a little darkly and vaguely, that the public are to understand from these 'recent' and 'remarkable discoveries' that Paleolithic man, scattered over Asia, Europe and America (and Africa?), was destroyed by the flood, where there was a flood, and by 'the extreme and rapid changes incident to the closing stages of the glacial period,' and that this gave rise to the 'sharp line of distinction between Paleolithic and Neolithic man,' and hence, by implication, that Neolithic man was the descendant of Noah and that the line of cultural evolution was from ark-building to 'smoothed stone implements.'

One is led to wonder how far respect for the Scriptures is fostered by 'remarkable discoveries' of this sort and by the much-trumpeted stage-play that preceded and accompanied them. * * *

THE MONGOOSE IN JAMAICA.

It seems to be almost impossible for writers of text-books to give a correct account of the mongoose in the island of Jamaica, and its effect upon the native fauna. In *Nature*, February 7, 1901, I took occasion to point out a peculiar error in the account of the animal in an excellent text-book of zoology; to-day I open Mr. J. W. Redway's *Elementary Physical Geography* (1900) and read that the mongoose 'did not lessen the number of cane-rats,' but 'exterminated one or two species of ground-bird.' As in the former note just mentioned, I must beg those who wish to discuss this subject to read Dr. J. E. Duerden's article in *Journal of the Institute of Jamaica*, July, 1896, p. 288.

Here the facts actually known are duly set forth, and among other things it is shown that the rats were destroyed in great numbers, while it seems doubtful whether the 'ground-birds' were actually exterminated in any instance.

AN EARTHWORK DISCOVERED IN MICHIGAN.

MR. G. N. HAUPTMAN, of Saginaw, Michigan, in a letter dated May, 1901, reports that 'there is on section 34, T. 21, N., R. 1 E., Ogemaw county, Mich., an earthwork [of horse-shoe shape]. The trench * * * is three feet' deep, and in it stand forest trees.

If any notice of this has ever been printed I should be glad to receive references to the same. I believe no note of this earthwork has previously been made, although four earthworks in the same county are well known and are recorded in the literature of archeology.

HARLAN I. SMITH.

PHYSIOLOGY IN THE SCHOOLS.

TO THE EDITOR OF SCIENCE: The writer has a 'horrible suspicion' that T. Hough imputes the physiological questions, to which he demurs, to him. He did not propound them. The high-school questions were taken from the text-book which the pupils had used, and if the text was legitimate, the questions were.

It is the writer's conviction that public school teachers are not generally qualified to teach physiology; that physiology proper is too abstruse for the grammar grades; and that the teacher in every grade should be expected to have a better knowledge of his subject than can be obtained from the elementary text placed in the hands of his pupils. Finally he may venture to express his fear that a little elementary knowledge of the reasons for the non-increase in stature of the human skeleton throughout life might not be amiss to his learned critic even.

S. W. WILLISTON.

SHORTER ARTICLES.

WHAT IS LIFE?

SOME thoughts, started by reading an article with the above title in *Nature*, Vol. 57, p. 138, 1898, by Horace Brown, and jotted down at that time, but laid aside, I have thought might perhaps interest the readers of SCIENCE, especially as the subject continues to be agitated.*

Heretofore in cases of dormant life, as in seeds kept for years, perhaps for centuries, or in dessicated infusoria, etc., in which under favorable conditions active life is revived, it has been supposed that very slow metabolic changes still go on during the state of dormancy—life is supposed to be feeble, but not extinct. The same was supposed to be the case in seeds or bacteria exposed to intense cold of — 180° to — 200° C. by Pictet or even — 250° by Dewar.

But it is now proved that at this temperature chemical affinity is destroyed and all chemical changes arrested, and therefore the chemical changes characteristic of life—metabolism—also must cease. But with the return of heat they revive. Therefore, in this case, life seems to spring spontaneously from dead matter. Must we then revive the old doctrine of spontaneous generation? If not we must change or greatly modify our conceptions of life.

From such experiments it is evident that, although life is, indeed, a distinct *form of energy*, yet its nearest alliance is with chemism. For as chemism is completely destroyed by extreme cold and again revived by heat, so life may be completely arrested by cold and again revived by heat—*if the molecular structure characteristic of living protoplasm* (whatever that may be) *remains unchanged.*

What then is the necessary condition of life—or, to put it clearly, what is the difference between *dead* protoplasm and *living* protoplasm, or rather protoplasm *capable of life?* Evidently it is not a difference in chemical composition, for no change in this regard takes place in the act of death. It is, I suppose, a difference in *molecular arrangement*—a difference in *allotropic condition.* As the necessary condition of chemical properties is a certain equivalent composition: so the necessary condition of vital properties is, in addition, a certain molecular constitution. But as equivalent composition may

**Nature*, Vol. 61, p. 67, 1899; Vol. 63, p. 420, 1901. *Revue Scientifique*, Vol. 15, p. 201, 1901, and SCIENCE, Vol. 12, p. 774, 1900.

remain, even though chemical activity be absent, so also the peculiar molecular constitution, characteristic of life may remain even though life—*i. e.*, active life—be absent. As chemism may be completely destroyed by cold and revived by heat, if the necessary condition, viz., a certain equivalent composition, remains: so life may be completely destroyed by cold, and again revived by heat if so be the necessary condition—a certain molecular constitution remains.

Again, Mr. Brown, in the article referred to, says that Spencer's definition of life, viz., 'a continuous adjustment of internal to external conditions' must be revised, since it applies only to *active* life and not to suspended life. I think not. Life in the true sense, *i. e.*, *actual* life must be active — the essential nature of life, as of all energy, is *activity*; but there is a necessary underlying condition, *i. e.*, a peculiar molecular constitution, which may be called *potential life*. As equivalent composition is potential chemism, which may under certain conditions become actual chemism, so a peculiar molecular constitution of protoplasm is potential life, which may under certain conditions become actual life. *Death* is not merely an *extinction* of life, *i. e.*, actual life, but also the *destruction* of the necessary condition of life, *i. e.*, the characteristic molecular structure of protoplasm. Extinction of life, therefore, is not necessarily *death*. There are therefore three conditions of protoplasm, viz.: (1) *living*, a condition in which life is actual; (2) *potentially living*, in which the necessary molecular constitution or vital constitution is present; and (3) *dead*, in which the vital constitution also is wanting.*

JOSEPH LE CONTE.

BERKELEY, CAL., May 24, 1901.

* Similar views on the molecular constitution of living protoplasms were brought out by me, in January, 1892 in a lecture before the Philosophical Society of Washington. *Bulletin*, Vol. XII., p. 29, 1892.

A 'SAND-BOW'—AN UNUSUAL OPTICAL PHENOMENON.

THE following description, based on personal observation, is presented without discussion of the optical principles involved.

On the evening of May 16, the writer was crossing the main ridge of Antelope Island—the largest land body within the area of the Great Salt Lake. As he began the descent on the eastern slope, there appeared between the island and the mainland what seemed at first glance to be segment of a brilliant rainbow of unusual width. It was evident, however, that no rain was falling in that direction. Clouds were gathering in the south and west, but the sun was yet unobscured. A wind setting toward the mainland had lifted from the dry flats large quantities of the 'oolitic sand,' with which the lake bottom and the recently dried patches on this side of the island are covered to a depth varying from a few inches to several feet. This so-called 'sand' consists of calcareous spherules, fairly uniform in size between the limits of No. 8 and No. 10 shot. The oolitic bodies are polished and exhibit a pearly luster.

It would seem that the outer spherical surfaces reflected the light in such a manner as to produce the bow. The colored column appeared almost to touch the lake bed, and its ends subtended with the observer an angle of about 40°. The prismatic colors were distinct, the red being outside, *i. e.*, away from the sun. In apparent width the column was fully double that of the ordinary rainbow. A fainter secondary bow was plainly visible beyond the primary, with the colors in reverse order. The phenomenon was so brilliant as to attract the attention of all members of the party, and it remained visible for over five minutes, then, as the sun sank lower, it rapidly died away.

The production of a color bow by reflection from the outer surfaces of opaque spherules is a new phenomenon to the writer. It is inexplicable on the principle of refraction and total reflection from the interior of transparent spheroids, according to which the rainbow is generally explained.

If phenomena similar or analogous to the foregoing have been observed, reports of the same would doubtless be of instructive interest.

JAMES E. TALMAGE.

NOTES ON INORGANIC CHEMISTRY.

PLATINUM IN ANTIQUITY.

PROFESSOR BERTHELOT reports in a recent number of the *Comptes Rendus* that on a metallic box from Egypt, covered with inscriptions, he found a portion of one of the characters made of platinum. The mass was too small for a complete analysis, but from its behavior toward aqua regia, it appeared to be native platinum. The date of the box was about 700 B. C. From two standpoints this discovery is of more than passing interest. It has been a much disputed question whether platinum was known to the ancients. Passages from the classics have been quoted which appear to some to be references to platinum, but this application is in every case very doubtful. A much stronger argument against the probability of platinum being known more than a few centuries ago, is, that until this discovery of Berthelot's, no trace of the metal has been found in any ancient remains. Had platinum been known, it is hardly conceivable that specimens of it should fail to be found somewhere among the multitudinous remains of antiquity. This present discovery really emphasizes the argument, for it would seem from the description given by Berthelot that this specimen of platinum was used by the workman unwittingly, resembling as it does some of the pale gold of Egypt. A second interesting point is that if Berthelot's conjecture be true that this is native platinum, obtained from the alluvial deposits of Nubia or the upper regions of the Nile valley, it is the first recorded occurrence of platinum in Africa, with the single exception of an observation of Aimé, in 1838, that some of the galena from Algeria contains a trace of platinum.

LEAD IN POTTERY GLAZES.

THERE has been much discussion in England the last few years regarding the use of lead in pottery glazes, with reference both to the health of the potters and to the dangers attending the use of lead-glazed vessels in culinary operations.

In continental potteries a lead glaze is in frequent use which seems to be far more resistant to the action of solvents than those in use in England. The subject was recently brought before the Chemical Society by Professor T. E. Thorpe and C. Simmonds, and an abstract of their work and of the discussion of their paper is found in the *Proceedings* of the Society. Examining a large number of glazes, they find that many of them are attacked by dilute acids, comparable with the acids found in the human system, such as the hydrochloric acid of the gastric juice. They find that the resistance depends upon the ratio of base to silica in the glaze. Provided that the ratio falls within certain limits, the amount of lead extracted under the prescribed conditions is always small, though the actual quantity of lead in the glaze may vary from zero to 50 or even 55 per cent. The amount of the other bases, such as alumina, lime and alkalies, may vary considerably and the silica may be replaced to some extent by other acids, as boric acid. It is to be hoped that American potters, as well as the English, may profit by these investigations, which after all only serve to bring out what has long been in practice in the potteries of Germany.

COSMIC DIFFUSION OF VANADIUM.

IN 1897 Hasselberg called attention to the occurrence of vanadium in many specimens of rutile, as had indeed been noticed by Sainte-Claire Deville as early as 1859. Hasselberg has now turned his attention to the examination of meteorites, and finds the presence of vanadium in all those examined of the stony type, while in metallic meteorites it is absent, save in a single specimen in which a very small quantity was found. He has gone over the work of Lockyer on the meteoric iron from Nejed and Obernkirchen, and finds that his observation that vanadium is present in these irons is erroneous. From these investigations he deduces the conclusion that a different origin is indicated for stony and for metallic meteorites.

J. L. H.

CURRENT NOTES ON METEOROLOGY.

ANNALS OF THE MONT BLANC OBSERVATORY.

VOL. IV. of the *Annales de l'Observatoire météorologique, physique et glaciaire du Mont Blanc (altitude 4,358 m.), publiées sous la Direction de J. Vallot,* contains several interesting

papers. A study, entitled 'Influence de la Pression Barométrique sur l'Action chimique de la Lumière directe du Soleil,' by Dr. M. Andresen, deals briefly with the work of Bunsen and Roscoe, and other investigators, and presents results obtained by the author at the Mont Blanc Observatory. A short paper by M. and Mme. Vallot deals with 'Expériences sur la Vitesse de la Circulation de l'Eau dans les Torrents et sous les Glaciers.' The most important contribution is one by M. Vallot, entitled 'Expériences sur la Marche et les Variations de la Mer de Glace.' This is an elaborate study, setting forth the results of observations made by the author on the Mer de Glace during the nine years 1891–1899. The observations included variations in level, variations in velocity, and variations in velocity in relation to variations in level. The paper is illustrated by means of a series of 61 plates, published in Vol. V. of the *Annales*, and deserves attention on the part of all who are interested in glacial problems. These two volumes are further evidence that M. Vallot's Observatory is doing effective scientific work.

THE MOON AND THE WEATHER.

A NEW journal, *Climat*, printed in four languages under the editorship of M. Demschinsky, of Torbino, Russia, and devoted to the publication of articles on the relation of the moon and meteorological phenomena, has recently been widely advertised. So far, three numbers of this magazine have been received. M. Demschinsky published, in Nos. 1 and 2 of *Climat*, a series of curves showing the probable course of the barometer and thermometer during the month of April at a large number of stations. The only comparison of the predictions with the facts of observed weather conditions that has thus far been given publicity is discussed by Dr. H. R. Mill, in *Symons's Monthly Meteorological Magazine* for May. Dr. Mill has made a careful comparison of the predicted conditions and of the actual weather observed in the cases of Aberdeen and of Valencia. The conclusion reached is, as might have been expected, that 'practically the forecasts as a whole appear to be valueless,' so far as these two stations are concerned.

NOTES.

IN the *National Geographic Magazine* for May an article by Gannett, on 'The General Geography of Alaska' (pp. 180-196), gives a good general account of the climate of that territory. This article forms one of the chapters of the volume dealing with the Harriman Expedition. The writer is inclined to believe "that if any part of Alaska can become of agricultural importance it is the interior rather than the Pacific coast. But it is doubtful whether even this region will admit of profitable farming. * * * However, as the higher rate of freight to the interior will have the effect of a protective tariff on home products, it may be possible to raise grain and vegetables at a profit under conditions which would be prohibitory on the coast."

The *Meteorological Observations for 1900*, as contained in the 13th Annual Report of the Colorado Agricultural Experiment Station, at Fort Collins, Colo., show that the mean annual evaporation at that station is 41.16 inches (10 years). This is the amount evaporated from a water surface in a tank 3 x 3 x 3 feet, flush with the ground.

Part VII. of the *Report of the Chief of the Weather Bureau for 1899–1900* contains the 'Meteorological Observations of the Second Wellman Expedition,' by Evelyn B. Baldwin, the leader of the present Baldwin-Ziegler Expedition.

R. DEC. WARD.

SCIENTIFIC POSITIONS UNDER THE GOVERNMENT.

THE U. S. Civil Service Commission announces that it is desired to establish an eligible register for the position of laboratory assistant in physics, National Bureau of Standards, Treasury Department. It will not be necessary for applicants to appear at any place for examination. The examination will consist of the following subjects:

Education and training	30
Original investigations	30
Experience	20
Thesis	20
Total	100

From the eligibles resulting from this examination it is expected that certification will

be made to two positions as laboratory assistant in physics, National Bureau of Standards, Treasury Department, one at a salary of $1,200 and the other at a salary of $1,400 per annum.

On the same day an examination, which also will not require attendance, will be held for two assistant agrostologists in the U. S. Department of Agriculture, with salaries respectively of $1,600 and $1,400 per annum. The Department states that the positions for which this examination is held require thorough training and practical experience in subjects pertaining to grasses and forage plants and animal foods, and the management of grass lands and forage crops in the field. The subjects and weights are:

Training and experience with special reference to:	
(*a*) Theory and practice in agriculture	25
(*b*) Teaching or scientific research	10
(*c*) Publications and editorial work	15
	50
Thesis	30
Plan (to be devised by the applicant) for experiments to solve any forage problem	20
Total	100

On the same day there will, further, be an examination, not requiring attendance, for the position of scientific aid with a knowledge of statistics in the Department of Agriculture.

This examination will consist of the following subjects:

College course (with bachelor's degree) or its equivalent	40
Post-graduate work and special qualifications	30
Thesis or other literature	30
	100

Applications will not be received from other than graduates of colleges receiving benefits from grants of land or money from the United States, unless it is shown that the applicants have pursued courses of instruction having an economic bearing which will qualifiy them for the work of the Department of Agriculture. Applicants must show the scope of the studies pursued and the length of time devoted to them, the standing in such studies, especially with regard to the subject of statistics, and the special qualifications which they have for work upon this subject. They must also submit a thesis upon the subjects of statistics, or in lieu thereof such other literature on the subject as may have been published over their own signature. The salary of the position is $40 per month and no person will be permitted to serve as a scientific aid for more than two years. Scientific aids who pass in an open competitive supplementary examination in some technical or scientific subject or subjects which may be held will be eligible to certification from such supplementary register to higher positions within the classified service, regardless of their services as scientific aids.

THE AMERICAN ASSOCIATION.

SECTION A. MATHEMATICS AND ASTRONOMY.

THE officers of the section, Professor James McMahon, chairman, and Professor George A. Miller, secretary, have received the following titles for presentation at the Denver meeting. They have not, however, yet been approved by the Sectional Committee:

'A Summary of the Salient Effects due to the Secular Cooling of the Earth': Professor R. S. WOODWARD, Columbia University.

'The Energy of Condensation of Stellar Bodies': Professor R. S. WOODWARD.

'Supplementary Report on Non-Euclidean Geometry': Professor GEORGE BRUCE HALSTED, University of Texas.

'On the Application of the Fundamental Laws of Algebra to Infinite Series': Professor FLORIAN CAJORI, Colorado College.

'Conditionally Convergent Series whose Product is Absolutely Convergent': Professor FLORIAN CAJORI.

'Report on Continuous groups': Professor H. B. NEWSON, Kansas University.

'The Great Meteor of December 7, 1900': Professor H. A. HOWE, University of Denver.

'Note on a Direct Solution of Kepler's Problem': Professor H. A. HOWE.

'The Next Appearance of Eros': Professor H. A. HOWE.

'On Systems of Isothermal Curves': Professor L. E. DICKSON, University of Chicago.

'On the Modular Function Associated with the Irrationality $s^3 = z(z-1)(z-x)(z-y)$': Dr. J. I. HUTCHINSON, Cornell University.

'The Physical Bases of Long-Range Seasonal Forecasts': Professor CLEVELAND ABBE, U. S. Dept. of Agriculture, Weather Bureau.

'Philosophy of Mathematics': Professor W. J. KERR, Agricultural College of Utah.

'Astronomy in the High Schools': MISS MARY PROCTOR, New York City.

'Concerning (*a*) the Concept of *n*-Dimensional Space and (*b*) Self-Reciprocal Geometries': C. J. KEYSER, Columbia University.

'On the Probable Densities of the Satellites of the Solar System': Professor T. J. J. SEE, U. S. Naval Observatory.

'Photometric Observations of Eros': HENRY M. PARKHURST, New York City.

'The History of Several Fundamental Theorems in the Theory of Groups of Finite Order': Dr. G. A. MILLER, Cornell University.

SECTION F. ZOOLOGY.

Professor Henry B. Ward, secretary, has sent the following circular letter to members of the section:

The next meeting of the A. A. A. S. will be held in Denver, Colorado, August 24th to 31st, 1901. The opportunity is good for bringing together a large number of zoologists and making the meeting particularly interesting.

A provisional program of papers to be read before Section F will be printed within a short time and all members are urged to send titles as soon as practicable.

Permit me to call your attention to Article 28 of the constitution which designates how the sectional committee shall complete the final program from abstracts of papers presented. Kindly conform to the conditions as given there. I enclose blanks for titles and abstracts of papers.

The work of section F would be much strengthened if a larger number of the morphologists of the country were enrolled in its membership. Now that each member of the association receives gratis the official journal, SCIENCE, it is certainly true that no one can afford to be without membership in the organization.

Will not each present member assist in the work of enlarging the membership roll?

CONVOCATION WEEK.

IT will be remembered that, at the instance of a committee of the American Association for the Advancement of Science, the Association of American Universities recently took action recommending that a convocation week be set aside for the meetings of scientific and learned societies. Columbia University, Cornell University, the Catholic University of America, Clark University and Johns Hopkins University have altered their calendars, so that exercises will not be held during the week in which January 1 falls. The schedules of California, Leland Stanford Junior, Michigan and Yale are already such that no exercises fall in this week. Pennsylvania and Princeton have arranged to permit all instructors who wish to attend the meetings held during convocation week to do so, and it is expected that they will alter their official calendars next year. The faculty of the University of Wisconsin has voted to lengthen the Christmas holidays so that convocation week will be left free till 1905; this action will doubtless be confirmed by the regents and made permanent. The only members of the Association of American Universities, whose sessions begin during the week above mentioned and which has not yet taken action are Harvard and Chicago. It is to be hoped, may we not say expected, that all the institutions of the United States and Canada will give their support to this important movement.

SCIENTIFIC NOTES AND NEWS.

THE HON. CHARLES D. WALCOTT, director of the U. S. Geological Survey, gave an address before the University of Chicago on June 17, his subject being 'The Relations of the National Government to Higher Education and Research.' We hope to publish this address next week.

DR. PAUL C. FREER, professor of general chemistry in the University of Michigan, has been granted leave of absence for one year to go to Manila on an important scientific commission on behalf of the Philippine Commissioners.

DR. WILLIAM Z. RIPLEY, of the Massachusetts Institute of Technology, has been invited to deliver the Second Huxley Memorial Lecture before the Anthropological Institute of Great Britain. The first lecture was given last year by Lord Avebury.

PROFESSOR BASHFORD DEAN, who is now working at the Misaki Marine Station of the Imperial University of Tokio, has presented a yacht, with a complete outfit for marine zoological work, to the institution.

THE Society of Arts, London, has awarded the Albert medal to King Edward, who for thirty-eight years has acted as president of the society.

COLUMBIA UNIVERSITY at its recent commencement exercises conferred its newly established D.Sc. on Mr. Arnold Hague, of the U. S. Geological Survey. The degree of LL.D. was conferred on Dr. W. H. Maxwell, superintendent of the New York schools, and the degree of M.S. on the Rev. Frank D. Gamewell, professor of physics at the University of Pekin, and on Dr. G. M. Lefferts, clinical professor of laryngology in the College of Physicians and Surgeons of the University.

THE valuable contributions to entomology made by William H. Ashmead, of the U. S. National Museum, were recognized by the Florida Agricultural College and Experimental Station in Lake City, Fla., at its recent commencement by the conferment of the honorary degree of A.M.

DUBLIN UNIVERSITY will confer its D.Sc. on W. Burnside, professor of mathematics, Royal Naval College, [Greenwich; W. E. Wilson, F.R.S., and Francis Joseph Edward Spring, C.I.E.

PROFESSOR H. S. CARHART has been appointed a delegate to the International Engineering Congress in Glasgow by the American Institute of Electrical Engineers. He has also been nominated as an honorary member of the Congress. He sails on August 13, and will attend both the Engineering Congress and the meeting of the British Association in Glasgow.

MR. F. W. HODGE has recently been appointed assistant in charge of office in the Smithsonian Institution, and to accept that appointment has resigned his position as ethnologist in the Bureau of American Ethnology. He continues as managing editor of the *American Anthropologist.*

DR. VICTOR C. VAUGHAN, of the University of Michigan, was elected president of the American Academy of Medicine at the annual meeting held in St. Paul, Minn., the first week in June.

DR. FREDERICK BEDELL, of Cornell University, will spend the coming year in Europe.

PROFESSOR J. CULVER HARTZELL, of the Illinois Wesleyan University, will be engaged during the summer in tracing certain partings in Indiana for the Indiana Geological Suruey.

PROFESSOR W. RAMSAY will lecture on the 'Inert Constituents of the Atmosphere,' and Professor Francis Darwin on 'The Movements of Plants,' at the approaching Glasgow meeting of the British Association.

PROFESSOR JAMES DEWAR gave the Bakerian Lecture before the Royal Society on June 13, his subject being 'The Nadir of Temperature and Allied Problems.'

THE William T. Lusk Memorial Science Prize has been awarded by the faculty of the University and Bellevue Hospital Medical College to S. S. Goldwater, for a paper entitled 'Notes on Blood Pressure in Man.' This prize is awarded to the member of the senior class presenting the best thesis which is the product of personal original research.

A MEMORIAL tablet to the late J. C. Porter, the botanist, was unveiled at Lafayette College in connection with the commencement exercises.

WE regret to announce the death of Professor Truman Henry Safford, which occurred at Williamstown, on June 13. Born at Royalton, Vt., in 1836, he had since 1876 occupied the chair of astronomy in Williams College.

DR. ARTHUR HAZELIUS, of Stockholm, the enthusiastic inspirer of the Northern Museum in that town, and the reviver of old Swedish customs, dances and costumes in the beautiful open-air museum known as Skansen, died on Whitmonday, mourned by all his countrymen.

M. MARÈS, known for his contributions to scientific agriculture, died at Montpelier, on May 9; Professor W. H. Heineke, for thirty-three years professor of surgery at Erlangen, has died at the age of sixty-six years.

JOHN VIRIAMU JONES, principal of, and professor of physics in, the University College of South Wales at Cardiff, died at Geneva on June

2. An obituary notice in the London *Times* states that he was born at Pontreporth, near Swansea, in 1856, he matriculated at London University in 1872, and won a University scholarship in geology, a subject in which he graduated as B.Sc. with first-class honors in 1875. In the preceding year he was elected Brackenbury scholar in natural science at Balliol College, Oxford; and in due course he was placed in the first class in mathematical moderations (1877), the final school of mathematics (1879), and the final natural science school (1880). For a short time he was demonstrator in the Clarendon Laboratory under Professor Clifton; but in 1881 he left Oxford to become principal of, and professor of mathematics and physics in, Firth College, Sheffield. Two years later, on the establishment of the University College of South Wales, he was appointed its first principal, also acting as professor of physics; and this position he retained up to his death. In 1894 he was chosen a fellow of the Royal Society, and in 1897 was elected a fellow of Jesus College, Oxford. His scientific work was mainly concerned with the measurement of electrical resistance, and he was a member of the committee of the British Association on that subject. In particular he was deeply interested in the determination of the standard ohm by the Lorenz method in absolute measure, *i. e.*, conditioned only by the units of length and time and the properties of the ether; he constructed a Lorenz apparatus for his laboratory at Cardiff, and took a prominent part in designing and testing another that was made in London for the McGill University. The cause of technical and scientific education in Wales owed much to his powers of organization, and he was vice-chairman of the Welsh Central Board for Intermediate Education, besides being the first Vice-chancellor of the University of Wales.

Dr. R. A. Daly, of Harvard University, has given up the plan of conducting a geological expedition to the North this summer.

Major Ronald Ross, of the Liverpool School of Tropical Medicine, expected to leave for Sierra Leone on June 8, in charge of the fifth malarial expedition from the school.

Alviso B. Stevens, assistant professor of pharmacy, in the University of Michigan, will spend a portion of the coming summer in New York City gathering old mortars, jars, shelf fixtures, etc., which will be made the nucleus of a collection illustrating the history of pharmacy.

A correspondent of the London *Times* states that Dr. Stein, writing from Khotan on April 22, reports the latest results of his excavations in northern Chinese Turkestan. He has unearthed a large number of fine stucco sculptures closely resembling the Greco-Buddhist relics of the northwestern Punjab, probably belonging to the first century of the Christian era. Great difficulty is being experienced in excavating the colossal Buddhas, but valuable photographs have been taken of them, while the smaller pieces have been removed. Dr. Stein has now a fine illustration of what the big Stupa with its chapel and court was like in Khotan at the time of the Han dynasty.

Professor William Patten, of Dartmouth College, has been granted leave of absence for the first semester of the next academic year. He will attend the International Congress of Zoologists in Berlin and afterwards explore the coast of the Baltic in Russia in search of specimens of *Cephalaspis* and other Ostracoderms. The United States Government, through its Geological Survey, has generously offered financial support in the undertaking. Dr. Patten's courses at Dartmouth will be given during his absence by Dr. J. H. Gerould.

Dr. Frank Russell has recently reported to the Bureau of American Ethnology a successful archeological trip through southeastern Arizona, in the course of which a number of hitherto unknown ruins were discovered and reconnoitered.

Professor W. H. Holmes recently returned from a visit to the South Carolina State College, at Columbia, where he supervised the arrangement and installation of the Babcock collection of stone implements. This collection, which represents the findings of the late Dr. Babcock during thirty years' residence in the district formerly occupied by the Catawba Indians, recently passed into the possession of the State; and it is now available for inspection, as well as for systematic study.

The U. S. Biological Survey, Department of Agriculture, has sent an expedition to Athabasca and Great Slave Lakes. The chief object is the collection of information and specimens illustrating the geographic distribution of mammals, birds, trees and shrubs in the region. The expedition is in charge of Edward A. Preble. Last year Mr. Preble was sent to Hudson Bay on a similar mission.

Reuter's correspondent in Berlin, telegraphing on June 1, says: The evening papers state that the international negotiations which have been proceeding with reference to the international protection of birds have now been concluded, and that the imperial chancellor has forwarded the draft of the international convention on this subject to the federal council with a recommendation that Germany should subscribe to it.

The Chamber of Commerce of Cambridgeshire, has unanimously passed a resolution declaring that it is desirable for the British government to establish an official seed-testing station.

The Antarctic exploring vessel *Discovery* left Dundee for London on June 3. A successor to Professor Gregory as leader of the scientific staff has not, we understand, yet been appointed.

The Rockefeller Institute for Medical Research was incorporated in New York State on June 13. The directors for the first year, as we have already stated, are: William H. Welch, of Baltimore, T. Mitchell Prudden, C. A. Herter, L. Emmett Holt, and Hermann W. Biggs, of New York; Simon Flexner, of Philadelphia, and Theobald Smith, of Boston.

A commission, consisting of Sir T. Lauder Brunton, Dr. T. Stevenson, Mr. A. G. Salamon, Dr. A. P. Luff, Dr. Samuel Buckley and Mr. Fletcher Moulton, K.C., M.P., appointed by the Manchester Brewer's Central Association to investigate the causes of the beer poisoning that has recently occurred in Great Britain has made its report. The Commissioners say: "It is clear that the most frequent source of arsenical contamination in beer is the use of malt which has been kiln-dried or malted with improper fuel containing arsenic. At the same time the experience of the late outbreak has shown that precautions must be taken against the presence of arsenic in brewing sugars and other materials (except, perhaps, malt adjuncts) on account of the serious consequences of any carelessness in manufacture which might introduce arsenic. Accordingly, we have considered what steps should in future be taken by brewers to protect themselves from any repetition of the recent disasters. We recommend that brewers should make it a rule to require a written guarantee of freedom from arsenic with all purchases of brewing materials of every kind. In addition to this we recommend that brewers should from time to time test the purity of their beer in respect of arsenic. The fact that yeast has a special affinity for arsenic affords an excellent method of demonstrating the purity of the materials used. If the yeast be tested for arsenic, it will readily show whether the wort is contaminated, for it will be many times richer in arsenic than the wort itself. It thus forms an excellent indicator of the presence of arsenic. In addition to frequent testing of the yeast, it would be advisable for the brewers to take control tests from time to time of their brewing sugars, finings and other materials."

UNIVERSITY AND EDUCATIONAL NEWS.

The bills in the Michigan Legislature to reduce the quarter-mill tax levied for the benefit of the university have been defeated. The annual income from this tax is now approximately $275,000, an increase over last year of $50,000.

The alumni of the Massachusetts Institute of Technology have subscribed $100,000 for a gymnasium, to be erected as a memorial to the late President Walker. Over 15,000 former and present students have sent subscriptions.

Columbia University has received an anonymous gift of $100,000 for the establishment of a department for the study of Chinese institutions, language and history.

President Patton announced at the commencement exercises of Princeton University that the authorities of the university had received $50,000 for an endowment fund for the library and $10,000 to establish a fellow-

ship in rhetoric. He also said that $150,000 of the $200,000 necessary for the erection of a new gymnasium had been insured by the alumni.

The University of Chicago has received $3,000 by the will of Marie J. Mergier to establish a scholarship in physiology.

Mrs. Caroline Stannard Tilton, of New Orleans, has given $50,000 for a Tilton Memorial Library Building at Tulane University.

It has now become known that Mr. and Mrs. James Speyer are the donors of the $100,000 for the experimental school of Teachers College, Columbia University. A site has been purchased near Amsterdam Avenue and 128th Street, and plans for the building, prepared by Mr. A. E. Josselyn, have been accepted.

Lincoln College and Decatur Industrial College have united, and will hereafter be called Milliken University, in recognition of a gift of $150,000 from Mr. James Milliken. Mr. A. R. Taylor has resigned the presidency of the State Normal College at Emporia, to become president of this institution.

The faculty of the University of South Dakota decided, by practically a unanimous vote, several months ago, that there should hereafter be but one degree granted for all courses of work, *viz.*, the Bachelor of Arts. Heretofore there have been three degrees granted, Bachelor of Arts, Bachelor of Science and Bachelor of Philosophy. This step was taken independently of the similar action by the Universities of Michigan and Minnesota which we recently reported.

The Yale Forest School has thirty-five applications for its summer session, which will be held next month at Milford, Pa.

A. D. Cole, professor of physics and chemistry in Denison University, has been called to a chair of physics in the Ohio State University. His position at Denison has been filled by the appointment of Professor Clark Chamberlin, of Colby College, Me.

W. G. Tight, professor of geology for thirteen years in Denison University, and editor of the *Bulletin of the Scientific Laboratories*, has been elected to the presidency and professorship of geology in the University of New Mexico.

H. C. Morene, a fellow at Clark University, has been appointed assistant professor of mathematics in Leland Stanford University.

Professor F. C. French has resigned the chair of philosophy at Vassar College, and Dr. H. Heath Bawden has been appointed associate professor of philosophy in the institution.

Frederick E. Bolton, Ph.D. (Clark) has been promoted to the head of the department of pedagogy in the State University of Iowa, succeeding Professor J. J. McConnell who has resigned to accept the superintendency of schools at Cedar Rapids, Iowa.

Professor Eugene Haanel has resigned the chair of physics in Syracuse University to accept an appointment as superintendent of mines of Canada.

Dr. Shepherd Ivory Franz, assistant in physiology in the Harvard Medical School, has been appointed instructor in physiology at Dartmouth College. He will give courses both in the Academic Department and in the Medical College.

Dr. Margaret Floy Washburn, warden of Sage College, has been appointed to a lectureship in psychology in Cornell University.

Paul Goode, who has been head of the department of Geography at the Normal School, Charleston, Ill., since its foundation, has recently received the degree of Ph.D. from the University of Pennsylvania and has been appointed instructor in geography in the same institution.

Dr. Herman C. Cooper, now of Lincoln, Nebraska, has been elected instructor in the department of chemistry of Syracuse University.

Sanford Bell, a Clark University student, will be temporary instructor in psychology and pedagogy at Mount Holyoke College next year.

The newly created third chair of zoology at the Imperial University of Tokio has been placed under the charge of Professor S. Watasé.

M. Th. Ribot, professor of experimental and comparative psychology at the Collège de France and editor of the *Revue Philosophique*, will retire from his chair on a pension at the end of the present academic year.

SCIENCE

A WEEKLY JOURNAL DEVOTED TO THE ADVANCEMENT OF SCIENCE, PUBLISHING THE OFFICIAL NOTICES AND PROCEEDINGS OF THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

FRIDAY, JUNE 28, 1901.

CONTENTS:

Relations of the National Government to higher Education and Research: DR. CHARLES D. WALCOTT 1001
The Royal Society of Canada: DR. H. M. AMI....1015
Science and the London University....1021
Scientific Books:—
Oppel's Lehrbuch der vergleichenden mikroskopischen Anatomie der Wirbelthiere. DR. B. F. KINGSBURY. *River Profiles*....1024
Societies and Academies:—
Zoological Club of the University of Chicago: DR. C. M. CHILD. *Torrey Botanical Club:* DR. M. A. HOWE. *The Minnesota Academy of Natural Sciences:* F. G. WARVELLE....1026
Discussion and Correspondence:—
Geology of China: PROFESSOR G. FREDERICK WRIGHT. *The Larynx as an Instrument of Music:* DR. JONATHAN WRIGHT....1029
Shorter Articles:—
Predetermined Root-hair cells in Azolla and other Plants: R. G. LEAVITT....1030
Quotations:—
Science at a Wesleyan University. Mr. Carnegie's Gift to Scottish Universities....1031
Current Notes on Physiography:—
The South Coast of England; The Origin of Fiords; Views of the Colorado Cañon; Kabo Volcano, Sumatra: PROFESSOR W. M. DAVIS....1032
Current Notes on Meteorology:—
Weather and Crops in Saxony; Rainfall and Forests in India; Periodicity of Severe Winters in England; Notes: R. DEC. WARD....1034

The British National Physical Laboratory....1036
Scientific Notes and News....1037
University and Educational News....1039

MSS. intended for publication and books, etc., intended for review should be sent to the responsible editor, Professor J. McKeen Cattell, Garrison-on-Hudson, N. Y.

*RELATIONS OF THE NATIONAL GOVERNMENT TO HIGHER EDUCATION AND RESEARCH.**

WHEN one considers the relations of the General Government to higher education and research, probably the first question to arise is, What, within the limitations imposed by the Constitution, can the Government do? Other pertinent inquiries are: What has been done? What is the present policy of the Government? How are its educational resources being utilized? What can be done that is not already being well done by our universities, colleges and technical institutions?

Many of our wisest and best statesmen and jurists believe that the General Government has no power, under the Constitution, to appropriate money for educational purposes, that important function having been left to the States. A glance backward over the history of colonial and national discussion and legislation is interesting and instructive.

HISTORY OF COLONIAL AND NATIONAL DISCUSSION.

In colonial times Oxford, Cambridge and Edinburgh were to American youth the centers of learning and higher education. These famous universities furnished all that

*Substance of address before the University of Chicago, delivered June 17, 1901.

was needed by the well-to-do student, and local colleges were given little attention and scant support. The founders of our college system were obliged to meet adverse conditions which developed the same qualities that led their compatriots to the conquest of the continent.

Early in the seventeenth century (1619) the Virginia Company granted ten thousand acres of land 'for the foundation of a seminary of learning for the English in Virginia.' At the suggestion of the King, the bishops of England, in the same year, raised fifteen hundred pounds to aid in the education of the Indians in connection with the proposed grant of land for the seminary. A portion of the land was occupied and the seminary was started under the direction of George Thorpe, a man of high standing in England. But the institution was short-lived. It, with its inmates and founder, perished in the Indian massacre of 1622.

In 1624 an island in the Susquehanna river was granted for the founding and maintenance of a university, but the undertaking lapsed with the death of its projector and of James I. and the fall of the Virginia Company.

For a time the movement for higher education was delayed, but in 1636 Harvard was founded; then William and Mary, in 1660; Yale, in 1701; the College of New Jersey, in 1746; the University of Pennsylvania, in 1751; Columbia, in 1754; Brown, in 1764; Dartmouth, in 1769; the University of Maryland, in 1784; the University of North Carolina, in 1789–'95; the University of Vermont, in 1791, and Bowdoin, in 1794.

The university spirit was well developed when the Constitutional Convention met in 1787. Madison, who was a member of the convention, acting in harmony with the known wishes of Washington, proposed to give the National Legislature power—

To establish a university.

To encourage, by premiums and provisions, the advancement of useful knowledge and the discussion of science.

Charles Pinckney also earnestly advocated a plan for the establishment of a national university, and Mr. Wilson supported the motion; but the matter was dropped, on the ground that Congress already had sufficient power to enact laws for the support of national education.

John Adams, who agreed with Washington in believing that 'scientific institutions are the best lasting protection of a popular government,' was always a strong advocate of the promotion of intelligence among the people. He secured the insertion in the constitution of Massachusetts of a provision recognizing the obligation of a State to pursue a higher and broader policy than the mere protection of the temporal interests and political rights of the individual. This provision read as follows:

It shall be the duty of legislatures and magistrates in all future periods of this Commonwealth, to cherish the interests of literature and the sciences * * * to encourage private societies, and public institutions, rewards and immunities for the promotion of agriculture, arts, sciences, commerce, trades, manufactures, and a natural history of the country.*

Washington sought to impress on Congress and the people his earnest conviction that the Government should establish and support a great national university. To this end he made a bequest in his will, and if Congress had treated it as the Legislature of Virginia treated his bequest for the endowment of Washington College, there would be to-day a fund sufficient to give adequate support to a great institution for investigation and original research in the capital city. In his will Washington expressed the fears he entertained as to the effect of foreign education on the youth of America, and the desirability of having an American university. His language was as follows:

* Massachusetts Public Statutes, 1882, p. 34.

That as it has always been a source of serious regret with me to see the youth of these United States sent to foreign countries for the purpose of education, often before their minds are formed, or they have imbibed any adequate ideas of the happiness of their own, contracting too frequently not only habits of dissipation and extravagance, but principles unfriendly to republican government, and to the true and genuine liberties of mankind, which thereafter are rarely overcome. For these reasons it has been my ardent wish to see a plan devised on a liberal scale which would have a tendency to spread systematic ideas through all parts of this rising empire, thereby to do away with local attachments and State prejudices, as far as the nature of things would, or indeed, ought to admit, from our national councils. Looking anxiously forward to the accomplishment of so desirable an object as this is (in my estimation), my mind has not been able to contemplate any plan more likely to effect the measure than the establishment of a university in a central part of the United States, to which the youth of fortune and talents from all parts thereof might be sent for the completion of their education in all the branches of polite literature, in arts, and sciences, in acquiring knowledge in the principles of politics and good government, and (as a matter of infinite importance, in my judgment), by associating with each other, and forming friendships in juvenile years, be enabled to free themselves in a proper degree from those local prejudices and habitual jealousies which have just been mentioned, and which when carried to excess are never-failing sources of disquietude to the public mind, and pregnant of mischievous consequences to this country.

Madison, though defeated in his effort to secure the approval of the Constitutional Convention in respect to the establishment of a national university, did not fail, when President, to call the attention of Congress to the subject. In his second annual message he said:

I cannot presume it to be unreasonable to invite your attention to the advantages of superadding to the means of education provided by the several States a seminary of learning instituted by the national legislature, within the limits of their exclusive jurisdiction, the expense of which might be defrayed or reimbursed out of the vacant grounds which have accrued to the nation within those limits. (Annals of Congress, 1810, '11, '13.)*

Various other attempts have been made from time to time to establish a national university. Blackmar says:

In 1796 a proposition was before Congress in the form of a memorial praying for the foundation of a university. (Ex. Doc., 4th Congress, 2d session.)

Again, in 1811 a committee was appointed by Congress to report on the question of the establishment of a seminary of learning by the National Legislature. The committee reported unfavorably, deeming it unconstitutional for the Government to found, endow and control the proposed seminary. (Ex. Doc., 11th Congress, 3d session.)

In 1816 another committee was appointed to consider the same subject, and again the scheme failed. (Ex. Doc., 14th Congress, 2d session.)*

When the disposition of the Smithson fund was under consideration (1838–1846), the subject of founding a national university was fully and freely discussed, and the plan was rejected by Congress.

Again in 1873 the matter was revived by the Hon. J. W. Hoyt, who from that time onward never ceased to labor diligently for a national university. Largely owing to his zeal and activity a committee of 100 was formed, various bills were introduced in Congress and a Senate Committee was created to establish a national university. But Congress always looked on the scheme with suspicion and not one of the various bills offered was ever acted upon by the Senate or House of Representatives.

The trend of opinion has been and is that the Government should not found a national university in the sense suggested by Washington and his followers. The Congress has, however, generously aided technical and higher education by grants of land to States and Territories for educational purposes.

The policy was inaugurated under the general authority of the famous Ordinance of July 13, 1787. Conformably thereto a

* 'The History of Federal and State Aid to Higher Education in the United States,' by Frank W. Blackmar, Ph.D.: Bureau of Education, Contributions to American Educational History, edited by Herbert B. Adams, No. 9, 1890, p. 32.

* Op. cit., pp. 39, 40.

contract was entered into between the Ohio Company and the Board of Treasury of the United States, on the 27th of July, 1787, whereby lot 16 in every township was given for the maintenance of public schools and not more than two complete townships were given perpetually for the purpose of a university, the land to be applied to the purpose by the legislature of the State.*

The most important act, after that of 1787, was that of 1862, granting land for the endowment of colleges for teaching agriculture and the mechanical arts. It is to be noted that by this act the responsibility was thrown entirely upon the States, and that, so far as the administration of the fund was concerned, it was State, not national, education.

The total grants of lands aggregate about 13,000,000 acres, or 20,000 square miles. Of this 2,500,000 acres, or 4,000 square miles, were for the establishment of higher institutions of learning. This land, divided among thirty States and Territories, gives an average of a little more than 80,000 acres, or about 130 square miles. For technical schools, called 'Colleges for the benefit of agriculture and the mechanical arts,' Congress has granted to forty-five States 10,500,000 acres, or about 16,000 square miles. This is an average of 230,000 acres, or about 360 square miles. Congress now grants annually to each of the forty-five States $25,000,† a total of more than a million dollars, all of which is expended under the direction of State boards.

The Government maintains, and has maintained since 1802, an academy for training its army officers; also, since 1845, an academy for training its naval officers. The Government does not maintain and never has maintained any institution for training its civil officers.

The policy of the Government, as gathered from its acts, has been to relegate the direct control of education to the States, aiding them in this work by grants of land, and in the case of technical education by grants of money also.

PRESENT POLICY OF THE GOVERNMENT.

Turning, now, to the question, What is the present policy of the Government? we have just seen that aid is given by grants of land, and in the case of the experiment stations by grants of money. As to the use of its literary and scientific collections by students its policy was defined by a public resolution of Congress approved April 12, 1892, which reads as follows:

Whereas large collections illustrative of the various arts and sciences and facilitating literary and scientific research have been accumulated by the action of Congress through a series of years at the national capital; and

Whereas it was the original purpose of the Government thereby to promote research and the diffusion of knowledge, and it is now the settled policy and present practice of those charged with the care of these collections specially to encourage students who devote their time to the investigation and study of any branch of knowledge by allowing to them all proper use thereof; and

Whereas it is represented that the enumeration of these facilities and the formal statement of this policy will encourage the establishment and endowment of institutions of learning at the seat of Government, and promote the work of education by attracting students to avail themselves of the advantages aforesaid under the direction of competent instructors: Therefore,

Resolved, by the Senate and House of Representatives of the United States of America, in Congress assembled, That the facilities for research and illustration in the following and any other Governmental collections now existing or hereafter to be established in the city of Washington for the promotion of knowledge shall be accessible, under such rules and restrictions as the officers in charge of each collection may prescribe, subject to such authority as is now or may hereafter

* Bancroft, 'History of the Constitution,' N. Y., 1882, Vol. II., pp. 435, 436. Also Geo. B. Germann, 'National Legislation concerning Education,' New York, 1899, pp. 19, 20.

† Act approved August 30, 1890. Statutes at Large, Vol. 26, p. 417.

be permitted by law, to the scientific investigators and to students of any institution of higher education now incorporated or hereafter to be incorporated under the laws of Congress or the District of Columbia, to wit:

One. Of the Library of Congress.
Two. Of the National Museum.
Three. Of the Patent Office.
Four. Of the Bureau of Education.
Five. Of the Bureau of Ethnology.
Six. Of the Army Medical Museum.
Seven. Of the Department of Agriculture.
Eight. Of the Fish Commission.
Nine. Of the Botanic Gardens.
Ten. Of the Coast and Geodetic Survey.
Eleven. Of the Geological Survey.
Twelve. Of the Naval Observatory.

The privileges of this act, it will be noted, are limited to scientific investigators and students of institutions incorporated under the laws of Congress or the District of Columbia. This limitation was removed by an act approved March 3, 1901, which reads as follows:

Joint resolution to facilitate the utilization of the Government Departments for the purposes of research, in extension of the policy enunciated by Congress in the joint resolution approved April 12, 1892.

WHEREAS * * *

Resolved, That facilities for study and research in the Government departments, the Library of Congress, the National Museum, the Zoological Park, the Bureau of Enthnology, the Fish Commission, the Botanic Gardens and similar institutions hereafter established shall be afforded to scientific investigators and to duly qualified individual students, and graduates of institutions of learning in the several States and Territories, as well as in the District of Columbia, under such rules and restrictions as the heads of the departments and bureaus mentioned may prescribe.

DISCUSSION AND ACTION IN RECENT YEARS.

Dr. Daniel C. Gilman, in 1897, summarized the situation in relation to the establishment of a national university, as follows:*

First, there is a strong desire, not only among the residents of the Federal city, but among the lovers and promoters of learning throughout the country, that the libraries, collections, instruments, and apparatus belonging to the Government should be opened to students, not as a favor, nor by exception, nor as a passing entertainment, but for study and experiment, according to suitable regulations, and especially under the guidance of such able teachers as may be already engaged in the service of the Government, or may be enlisted hereafter for the particular offices of education. So far as this there would be a unanimous, or nearly unanimous, assent.

Second, the universities existing in Washington and near to it, including those of New England, would regard with disfavor, and probably with distrust, an effort to establish, by congressional action, the University of the United States. In some places there would be positive opposition. * * *

Third, outside of academic circles, as well as inside, there is a great distrust of the principle that Congress should provide for and direct university education. The fears may be foolish. It is easy to laugh at them. Apprehensions may be pronounced groundless; nevertheless it will be difficult to get rid of them. There will be an ever-present expectation of political interference, first in the governing body, then in the faculty, and finally in the subjects and methods of instruction. It is true that partisan entanglement may be avoided, but it will be difficult indeed to escape the thraldom.

In the same article it is suggested that the Smithsonian Institution take charge, so that—

The literary and scientific institutions of Washington may be associated and correlated so far, and so far only, as relates to the instruction and assistance, under proper restrictions, of qualified students. * * * Such a learned society may be developed more readily around the Smithsonian Institution, with less friction, less expense, less peril, and with the prospect of more permanent and widespread advantages to the country, than by a dozen denominational seminaries or one colossal University of the United States.

In February, 1899, Dr. William H. Dall, of the Geological Survey, outlined very clearly the conditions and possibilities for post-graduate work in Washington, and urged that if any organization was attempted it should be free from Government control.*

Little, if any, advantage was taken of the congressional resolution of 1892, which restricted opportunities for study and re-

search to the educational organizations of the District of Columbia, but with the recent rapid growth of the Department of Agriculture, a considerable number of students have been given opportunity for study and practical training. Secretary Wilson has taken the lead in actually bringing qualified students into the laboratories of a Government department and setting them to work. He has inaugurated a new class, called 'student assistants,' and has demonstrated its practical value. In his report for 1898 he says:*

> George Washington, by his will, left property to be devoted to university education in the District of Columbia. There is no university in the land where the young farmer may pursue post-graduate studies in all the sciences relating to production. The scientific divisions of the Department of Agriculture can, to some extent, provide post-graduate facilities. Our chiefs of division are very proficient in their lines; our apparatus the best obtainable; our libraries the most complete of any in the nation. We can direct the studies of a few bright young people in each division, and when the department requires help, as it often does, these young scientists will be obtainable.
>
> They should be graduates of agricultural colleges and come to the Department of Agriculture through a system of examination that would bring the best and be fair to all applicants. The capacity of the department is limited, but something can be done that will indicate to Congress the value of the plan. The department often needs assistants to take the place of those who are tempted to accept higher salaries in State institutions. The opening of our laboratories to post-graduate work would provide an eligible list from which to fill vacancies as they occur, supply temporary agents, and be a source from which State institutions might get assistance in scientific lines.

The Department of Agriculture naturally turns to the professedly agricultural colleges for its student assistants, but if other institutions gave their students such instruction as would qualify them for the work of that department, there seems to be no good reason why they should be discriminated against.

* 'Yearbook of the Department of Agriculture,' 1898, pp. 18, 19.

As the development of the work progressed in the scientific bureaus, it became impossible to find men qualified for the permanent positions open to them. Graduate students were obtainable, but they were without practical training for the work. The Civil Service Commission was called on, but it had no eligibles on its lists. The only way out of the difficulty seemed to be for the heads of the scientific bureaus to select bright, well-educated young men and train them; this they have been doing for several years. In the Geological Survey graduate students, being the best men available for temporary field assistants in both geologic and topographic work, are given preference. The Survey cooperates with such institutions of learning as are willing to give the advanced instruction necessary to fit students to engage in the several special lines of investigation. This cooperation consists mainly in the employment of graduate students and instructors. A high standard is maintained by the character of the examinations held for selecting temporary employés. For example, in the examination for temporary geologic assistants held April 23 and 24, 1901, the applicants were obliged to meet the following requirements:

> First. To write an essay of more than a thousand words, setting forth either the course and results of an original geologic investigation by the applicant or the main features of the geology of some State.
>
> Second. To answer satisfactorily seven questions, so selected as to test the applicant's knowledge of the science of geology in general.
>
> Third. To select one of the five specialties, stratigraphy, petrography, paleontology, physiography, and glaciology, and make clear the possession of an adequate knowledge thereof.

The weight given to the various subjects was as follows:

Geological essay, including composition and drawing	30 per cent.
General geology	15 per cent.
Special geology	25 per cent.
Education and experience	30 per cent.

Fifty-two persons took this examination, and of these forty-six made an average of more than 70 per cent. The successful applicants have received degrees for academic and graduate study from the following institutions of learning:

Harvard University	13
Johns Hopkins University	6
University of Chicago	6
Yale University	5
Cornell University	4
University of Wisconsin	2
University of California	2
University of Kansas	2
Stanford University	2
Iowa State College	2
Amherst College	2
Munich	2
Alfred University	1
Beloit College	1
Columbia University	1
Columbian University	1
Cornell College, Iowa	1
Denison University	1
Gates College	1
German Wallace College	1
Hamilton College	1
Heidelberg College, Ohio	1
Heidelberg, Germany	1
Indiana State University	1
Lafayette College	1
Lawrence Scientific School	1
Moore's Hill College	1
Ohio Wesleyan University	1
University of Illinois	1
University of Minnesota	1
University of Missouri	1
University of Nebraska	1
University of the City of New York	1
University of Oregon	1
University of South Carolina	1
Williams College	1

The total of forty-six successful applicants divides by State residence as follows:

Massachusetts	9
Illinois	7
New York	7
Iowa	3
Connecticut	2
Indiana	2
Missouri	2
Pennsylvania	2
South Carolina	2
California	1
Colorado	1
Kansas	1
Kentucky	1
New Jersey	1
Ohio	1
Oregon	1
Tennessee	1
Wisconsin	1
Wyoming	1

Of those who passed, forty have received appointments to temporary positions. It is probable that 50 per cent. of the number will become permanent members of the Survey; 38 per cent. already hold or will obtain positions as instructors in educational institutions, and the others will enter State surveys and private employment.

Of the temporary geologic force of the Survey other than those mentioned, and who receive pay only when actually employed, the majority are connected with institutions of learning, as follows:

Harvard University	4
University of Chicago	4
University of Wisconsin	3
Columbia University	2
Stanford University	2
Yale University	2
Amherst College	1
Clark University	1
Colby University	1
Johns Hopkins University	1
Ohio State University	1
University of Michigan	1
University of California	1
University of Virginia	1
University of West Virginia	1
University of South Dakota	1
Vanderbilt University	1
Williams College	1

The preceding statements illustrate the intimate relation existing between one division of one bureau of one department of the Government and the higher educational interests of the country. A close analysis of the personnel of other bureaus will doubtless show that the Government is thus indirectly doing a great work in fostering higher education and research, and it will

at the same time be seen that the educational institutions of the country are training men and women for the highest scientific and technical positions in the Government service.

The Association of Agricultural Colleges and Experiment Stations several years ago realized the importance of giving its students the training which would enable them to meet the conditions prevailing in Washington. A committee of graduate study in Washington was appointed in July, 1897.* In the following April this committee met in Washington to study the conditions under which work might be undertaken. In a report made in November, 1898, the committee said in part:

After long deliberation and full discussion your committee are unanimously of the opinion that the time is ripe for expeditious action.

The inquiries and investigations so far made lead the committee to the conclusion that it is entirely practicable to provide for the use of the Library of Congress and the collections of the Smithsonian Institution, the National Museum, and of the various scientific and other bureaus in the several departments of the general government, by graduate students of the land grant and other colleges, for study and research, and that it is also practicable to organize, coordinate, and direct such work so as to make it eminently effective.

The committee has been greatly desirous that some existing agency be found to undertake such work of organization, coordination, and direction, and have naturally turned to the Smithsonian Institution as the one best fitted for the purpose.

The committee is unable, at the present time, to present a complete outline of the legislation necessary to effect the general purposes of the resolution. It submits tentatively, however, that Congress might be asked to provide for the establishment of an administrative office in Washington, preferably in the Smithsonian Institution, in which graduate students of the institutions we represent, and others as well, might be enrolled and directed to the appropriate departments (Bull. 65, Dept. Agriculture, pp. 61, 62).

In a report by the subcommittee of the committee of the National Educational Association on the establishment of a national university, we find that the active cooperation of the Smithsonian Institution is contemplated in the conduct of the proposed school or bureau, but that the committee of the regents of the Smithsonian Institution feel that the powers of the institution, as at present organized, are insufficient to embrace the work proposed.*

At a meeting of the Smithsonian regents held on January 24, 1900, Dr. Alexander Graham Bell introduced a resolution to the effect that Congress be asked to provide for an assistant secretary of the Smithsonian Institution in charge of research in the Government departments, etc. The resolution was referred to a committee, which, on January 23, 1901, reported a modified form of the original resolution. This modified form was adopted by the board of regents. It reads as follows:

In order to facilitate the utilization of the Government departments for the purpose of research, in extension of the policy enunciated by Congress in the Joint Resolution approved April 12, 1892:

Resolved, That it is the sense of the board that it is desirable that Congress extend this resolution so as to afford facilities for study to all properly qualified students or graduates of universities, other than those mentioned in the resolution, and provide for the appointment of an officer whose duty it shall be to as-

* *Resolved*, That a committee of five be appointed by the President to investigate, consider, and, if practicable, devise a plan whereby graduate students of the land grant and other colleges may have access to and the use of the Congressional Library and the collections in the Smithsonian Institution, the National Museum, and the scientific bureaus of the various departments at Washington of the United States Government for the purposes of study and research, said plan to include suggestions as to the manner in which such work may be organized, coordinated, and directed to the best advantage; the composition and organization of such a staff as may be necessary to properly coordinate and direct such work, and also an outline of such legislation as may be necessary to effect the general purposes of this resolution. (Proc. Twelfth Annual Convention of the Assn. Amer. Agricultural Colleges and Experiment Stations, held at Wash., D. C., Nov. 15-17, 1898, being Bull. 65, Dept. Agriculture, p. 58.)

* SCIENCE, N. S., Vol. XI., March 16, 1900, pp. 410-414.

certain and make known what facilities for research exist in the Government departments, and arrange with the heads of the departments, and with the officers in charge of the Government collections, on terms satisfactory to them, rules and regulations under which suitably qualified persons might have access to these collections for the purpose of research with due regard to the needs and requirements of the work of the Government; and that it should also be his duty to direct, in a manner satisfactory to the heads of such departments and officers in charge, the researches of such persons into lines which will promote the interests of the Government and the development of the natural resources, agriculture, manufactures and commerce of the country, and (generally) promote the progress of science and the useful arts, and the increase and diffusion of knowledge among men.

This resolution referred the matter to Congress. Many members of both Houses doubt whether Congress has power under the Constitution to appropriate money raised by taxation for purposes of education, and nothing was done by Congress, as the resolution was not officially brought before it.

ORGANIZATION OF THE WASHINGTON MEMORIAL INSTITUTION.

At this point the Washington Academy of Sciences undertook to give the proposition to utilize the resources of the Government for higher education and research a practical form, independent of direct Government support or control. For several months the Academy had been conferring with the George Washington Memorial Association relative to erecting in Washington a memorial building to be dedicated to science, literature and the liberal arts. The president of the Academy suggested to the Memorial Association that it should so amend its act of incorporation that it could cooperate with the Academy in carrying out the objects common to both organizations. The suggested amendments were made, and an agreement was entered into substantially as follows:

The objects of the George Washington Memorial Association are, first, as implied in its name, the creation of a memorial to George Washington; and second, as stated in its amended act of incorporation, the increase in the city of Washington of opportunities and facilities for higher education, as recommended by George Washington in his various annual messages to Congress, notably the first—*i. e.*, 'the promotion of science and literature,' substantially as set forth in his last will, and by and through such other plans and methods as may be necessary or suitable. The object of the Washington Academy of Sciences, the federated head of the scientific societies of Washington, is the promotion of science, the term 'science' being used in its general sense—'knowledge, comprehension of facts and principles.'

The two organizations agreed, first, that, although American universities have so developed since George Washington's time that they fulfill many of the objects of the national university outlined by him as desirable for the youth of the United States, there is still need of an organization in the city of Washington which shall facilitate the utilization of the various scientific and other resources of the Government for purposes of research, thus cooperating with all universities, colleges and individuals in giving to men and women the practical post-graduate training which cannot be obtained elsewhere in the United States and which is now available only to a limited degree in the city of Washington, and, second, that the best method of securing the objects for which both organizations stand is the establishment, within the district selected by Washington as a site for the permanent seat of Government of the United States, of an institution whose object shall be the realization of Washington's repeatedly expressed wish and recommendation that provision be made for the *promotion of science and literature.*

The membership of the Academy in-

cludes most of the leading scientific men of Washington and the country at large. The Academy, familiar with conditions in Washington and with the efforts of the committees of the Association of Agricultural Colleges and Experiment Stations and the National Educational Association, and knowing that the Smithsonian Institution would not, under its limitations, take an active part, realized that the time was opportune for a new organization. Its committee drafted and secured the passage of the act of Congress approved March 3, 1901. The committee next drafted a plan of organization, which was accepted by the Academy and Memorial Association. The plan was, in brief, as follows:

1. *Organization.*—A private foundation independent of Government support or control.

2. *Objects.*—(*a*) To facilitate the use of the scientific and other resources of the Government for research.

(*b*) To cooperate with universities, colleges and individuals in securing to properly qualified persons opportunities for advanced study and research.

3. *Government.*—The policy, control and management to vest in a board of fifteen trustees, and in addition there shall be an advisory board composed chiefly of heads of executive departments, bureaus, etc.

Articles of incorporation were then drawn up and executed, and were filed on May 20, 1901. They read as follows:

Articles of Incorporation, Washington Memorial Institution.

We, the undersigned, persons of full age and citizens of the United States, and a majority of whom are citizens of the District of Columbia, being *desirous to establish* and maintain, in the city of Washington, an institution in memory of George Washington, for promoting science and literature, *do hereby associate ourselves* as a body corporate, for said purpose, under the general incorporation acts of the Congress of the United States enacted for the District of Columbia; *and we do hereby certify* in pursuance of said act as follows:

First. The name or title by which such institution shall be known in law is the Washington Memorial Institution.

Second. The term for which said institution is organized is nine hundred and ninety-nine years.

Third. The particular *business and objects* of the institution are: to create a memorial to George Washington, to promote science and literature, to provide opportunities and facilities for higher learning, and to facilitate the utilization of the scientific and other resources of the Government for purposes of research and higher education.

Fourth. The *number of its trustees* for the first year of its existence shall be fifteen.

In testimony whereof we have hereto set our names and affixed our seals, at the city of Washington, in the District of Columbia, on the 16th day of May, 1901.

DANIEL C. GILMAN. [SEAL.]
CHARLOTTE EVERETT HOPKINS. [SEAL.]
C. HART MERRIAM. [SEAL.]
GEORGE M. STERNBERG. [SEAL.]
CHAS. D. WALCOTT. [SEAL.]
CARROLL D. WRIGHT. [SEAL.]

DISTRICT OF COLUMBIA, *ss:*

Be it remembered that on this 16th day of May, A.D. 1901, before the subscriber personally appeared the above-named Daniel C. Gilman, Charlotte Everett Hopkins, C. Hart Merriam, Geo. M. Sternberg, Chas. D. Walcott, and Carroll D. Wright, to me personally known and known to me to be the persons whose names are subscribed to the foregoing instrument of writing, and severally and personally acknowledged the same to be their act and deed for the uses and purposes therein set forth.

Given under my hand and official seal the day and year above written.

[SEAL.] (Signed) HERBERT W. GILL,
Notary Public.

On May 27 fifteen trustees were elected, and on June 3 the officers for the first year were chosen. Lists of these are given herewith:

Board of Trustees, Washington Memorial Institution.

1. Dr. Edwin A. Alderman, President Tulane University.
2. Dr. A. Graham Bell, Regent Smithsonian Institution.
3. Dr. Nicholas Murray Butler, Professor of Philosophy and Education, Columbia University.
4. Dr. C. W. Dabney, President University of Tennessee.
5. Dr. D. C. Gilman, President Johns Hopkins University.
6. Dr. A. T. Hadley, President Yale University.

7. Dr. William R. Harper, President University of Chicago.

8. Mrs. Phœbe A. Hearst, Regent University of California.

9. Mrs. Archibald Hopkins, President George Washington Memorial Association.

10. Dr. C. Hart Merriam, Chief United States Biological Survey.

11. Dr. Cyrus Northrop, President University of Minnesota.

12. Dr. H. S. Pritchett, President Massachusetts Institute of Technology.

13. Dr. George M. Sternberg, Surgeon-General United States Army.

14. Hon. Charles D. Walcott, President Washington Academy of Sciences, and Director United States Geological Survey.

15. Hon. Carroll D. Wright, Commissioner of Labor.

Officers of Washington Memorial Institution.

Daniel C. Gilman, director.

Charles D. Walcott, president board of trustees.

Nicholas Murray Butler, secretary board of trustees.

C. J. Bell, treasurer.

An advisory board also was selected, as follows:

President of the United States.
Chief Justice of the United States.
Secretary of State.
Secretary of the Treasury.
Secretary of War.
Secretary of the Navy.
Secretary of the Interior.
Secretary of Agriculture.
Postmaster-General.
Attorney-General.
Secretary of the Smithsonian Institution.
Commissioner of Education.
Librarian of Congress.
Commissioner of Labor.
Commissioner of Fish and Fisheries.
President of the Civil Service Commission.
President of the National Academy of Sciences.
President of the National Educational Association.
President of the Association of American Universities.
President of the Association of Agricultural Colleges and Experiment Stations.
Dr. Charles W. Eliot.

The duties of the director, as defined in the by-laws are as follows:

The director shall be the chief executive of the institution, and, under the guidance and control of the executive committee, shall conduct its affairs. He shall make all arrangements for cooperation between the institution, on the one hand, and the Government, universities, colleges, learned societies, and individuals on the other, subject to the approval of the executive committee.

EXISTING FACILITIES FOR STUDY AND RESEARCH.

The policy of the Government, as expressed, is to aid in higher education and research by granting the use of such facilities as are at its command in the District of Columbia. The direct control of higher education has been relegated to the States, the Government aiding by grants of land, and in the case of technical education at agricultural experiment stations by grants of money.

The Government has carried on original research for its own purposes in the District of Columbia through grants of money to its various scientific and technical bureaus, notably those of the Department of Agriculture, the Coast and Geodetic Survey, the Geological Survey, the National Museum, the Bureau of Ethnology, the Fish Commission, the Bureau of Education, the Library of Congress, etc.

Of the total sum appropriated for the fiscal year 1901, at least 25 per cent., or $2,020,000, may be regarded as expendable for scientific and research work and in the interest of higher education. The appropriations for the year are as follows:

Department of Agriculture:		
Weather Bureau	$1,168.320	
Bureau of Animal Industry	1,154,030	
" " Plant Industry	204,680	
" " Forestry	185,440	
" " Chemistry	35,800	
" " Soils	109.140	
Division of Entomology	36,200	
" " Biological Survey	32,800	
Agricultural Experiment Stations	789,000	
Miscellaneous	222,000	
		$3,937,410.00
War Department:		
Army Medical Museum and Library		25,000.00
Navy Department:		
Hydrographic Office	$136,518.00	
Naval Observatory	226,461.08	
Nautical Almanac	15,900.00	
		378,879.08

Interior Department:		
Geological Survey	$1,023,423.11	
Bureau of Education	59,370.00	
		1,082,793.11
Treasury Department:		
Coast and Geodetic Survey	$830,345	
Bureau of Standards	167,140	
Marine Hospital	71,100	
		1,068,585.00
Smithsonian Institution:		
National Museum	$289,400	
Bureau of American Ethnology	50,000	
National Zoological Park	80,000	
Astrophysical Observatory	12,000	
International Exchanges	24,000	
		455,400.00
Commission of Fish and Fisheries		543,120.00
Botanic Gardens		24,393.75
Library of Congress		565,345.00
Total		$8,080,925.94

This is about ten cents per capita for the entire population.

Great collections of books, specimens, statuary, paintings, instruments, apparatus, etc., have been assembled in Washington.

Libraries.—Statistics of the principal libraries reveal the presence of a large number of books, maps and pamphlets, many collections of which are exceptionally complete in special lines of research, notably those of the Departments of State and Agriculture, the Geological Survey, the Naval Observatory, the Surgeon-General's Office, the Bureau of Education, the Museum of Hygiene, the Patent Office, the National Museum, and special collections in the Library of Congress. The principal libraries are here listed:

	Books.	*Pamphlets.*	*Maps.*
Library of Congress	1,000,000*		55,700
" " Smithsonian Institution	250,000†		
" " U. S. Supreme Court	80,000†		
" " Army Medical Museum	135,058	229,546	
" " Dept. of Agriculture	68,000		
" " Bureau of Education	81,872	140,004	
" " Patent Office	74,140		
" " Department of State	63,000	2,500	
" " Geological Survey	47,600	77,027	29,185
" " National Museum	25,000	30,000	
" " Coast and Geodetic Sur.	16,405	6,178	25,000
" " Weather Bureau	18,000	5,000	
" " Museum of Hygiene	11,969		
Library of Hydrographic Office	3,000		
" " Bureau of Ethnology	12,000	4,000	
" " Bureau of Statistics	6,000	5,000	
" " Department of Justice	30,000		
" " Department of Labor	7,051	4,454	
" " Corcoran Gallery of Art	2,500		
" " Treasury Department	22,000	3,000	
" " War Department	49,000	2,000	
" " Navy Department	33,635		
" " Interior Department	15,000		
" " Post Office Department	12,000		
" " Light-House Board	5,000		
" " War Records Office	2,000		
" " Naval Observatory	20,000	4,000	
" " Naut. Almanac Office	2,200	2,500	
	2,092,430	515,209	109,885

* Books and pamphlets.

† These figures are included in the 1,000,000 assigned to the Library of Congress.

Other libraries in the District bring the grand total to more than 2,500,000 volumes, 570,000 pamphlets, and 110,000 maps, assembled in large part by specialists in every field. All the libraries are accessible and are maintained at a high standard of efficiency.

Collections.—The collections of the National Museum, though inadequately housed and with insufficient laboratories for the work of the regular museum force, are, nevertheless, of such character and are so arranged for exhibition and study that they will be of great service to all who may wish to use them. Under the present organization of the museum there are three departments: Anthropology, Biology and Geology. All the exhibits are systematically classified and placed in immediate charge of specialists acquainted with the results of man's activity in almost every form in which such results admit of study and representative exhibition. As provided by statute, the collections made by the Geological and other surveys are deposited in the National Museum after they have been used by the organization which collected them. This has resulted in an immense accumulation of material, much of which has not yet been fully studied, and upon which, when sufficient laboratory space is provided, students can be employed under the oversight of the specialists in charge.

The collections of the Army Medical Museum have a world-wide reputation and contain a great quantity of unique and valuable material. There are large collections of living animals at the Zoological Park; and there is a fine series, illustrating fish culture, at the Fish Commission building. The museum of the Agricultural Department contains valuable material, especially the working collections of the different divisions, and the Botanic Gardens are capable of great development under scientific direction. To the student interested in the development of American inventive genius and the industries represented by patents the collection of models and drawings in the Patent Office offers exceptional opportunities. Mention should also be made of the collections of apparatus of various kinds in Government laboratories, and of the illustrations of the evolution of apparatus in the National Museum and Smithsonian Institution.

In art, while the collections are not so large as in other lines, yet there is a collection of excellent quality in the Corcoran Gallery of Art, which maintains a free school. In this school day and night classes are taught the arts of drawing and painting, free of tuition fees or charge of any kind. Up to the close of 1899, 844 pupils had received instruction in the day school and 1,483 in the night school.

The Naval Observatory has a good equipment, including a chart and a chronometer depot, an extensive collection of instruments used in taking astronomic photographs, a fine telescope and transit instruments used in carrying on its routine work.

The newly created National Bureau of Standards is to have buildings and a fine equipment of all necessary apparatus. When fully developed it will be second to none in the character and value of its scientific and practical work. The functions of this bureau are defined in the organic act as follows:

> The functions of the bureau shall consist in the custody of the standards; the comparison of the standards used in scientific investigations, engineering, manufacturing, commerce and educational institutions with the standards adopted or recognized by the Government; the construction, when necessary, of standards, their multiples and subdivisions; the testing and calibration of standard measuring apparatus; the solutions of problems which arise in connection with standards; the determination of physical constants and the properties of materials, when such data are of great importance to scientific or manufacturing interests and are not to be obtained of sufficient accuracy elsewhere.

Law and Diplomacy.—The State Department has accumulated a valuable library relating to international law. The law library of Congress contains more than 50,000 volumes exclusively legal in character, and accommodations are provided for students who wish to use it. The School of Diplomacy of Columbian University is one of the unique features of the educational organizations of Washington. The Supreme Court of the United States and the Court of Claims bring together the foremost American lawyers. There is also the Supreme Court of the District of Columbia, which has the common-law, equity, and probate jurisdiction of State courts, besides that of the circuit and district courts of the United States.

There are, of course, unequaled opportunities for studying the development of legislation and for meeting the leading statesmen and public men of the country.

Medicine.—The Army Medical Museum has one of the finest collections in existence of recent pathologic specimens. These, taken with the library of the Surgeon-General's Office, in the same building, afford a rare opportunity for the medical student. In the adjoining National Museum there is a most complete collection illustrating the *materia medica* of the United States and of foreign countries. There are also several

hospitals, at each of which clinical instruction is given.

Congress has enacted that these vast collections and resources shall be available for higher education and research, but it has not provided the machinery for making them practically available. As in the case of the grants of land to colleges, Congress provides facilities and indirectly the means, but it leaves to other agencies the task of devising ways and means to make them practically useful.

The Government is obliged to train most of its specialists. Opportunities for post-graduate study and research exist at a few of the strongest universities, colleges and technical schools of the country, but at best the training given, except in a few branches, is of a preparatory character. Most American youth who are ambitious to pursue higher study and research have little opportunity, owing largely to the fact that the instructor's duties leave him scarcely any time for research and practical work with the student. Post-graduate students seek instructors distinguished for research, even to the extent of undergoing many privations and leaving their country. In the city of Washington the Government has assembled the largest body of original investigators to be found in any one place in the world. Most of these investigators are willing to train suitably qualified students, because of the assistance the students can give them in the work they have in charge, the method being to have the students do actual, practical work, and not to instruct them in the ordinary sense of the word. An unofficial inquiry indicates the following as a possible number of instructors and students in the various departments and bureaus at Washington:

	Instructors.	*Students.*
1. History and diplomacy	1	5
2. Historical research	5	10
3. Library administration and methods	5	15
4. Statistics	2	5
5. Magnetism	1	2
6. Meteorology	5	15
7. Tides	1	2
8. National Standards (Bureau of)	....	....
9. Astronomy	3	8
10. Physics	2	3
11. Hydrography	5	10
12. Cartography, etc	2	5
13. Topography	10	20
14. Chemistry	6	10
15. Mineral resources	1	5
16. Geology	10	17
17. Paleontology	5	7
18. Animal industry	10	25
19. Anthropology and ethnology	4	13
20. Zoology	34	50
21. Botany	11	25
22. Forestry	10	20
	133	272

With the development of a well-considered plan, just alike to the student and to the officers of the Government, the number of students—or, more strictly speaking, student assistants—would increase from year to year. Most of the students would naturally come from institutions of learning; in all such cases the student should be certified to the director of the Washington Memorial Institution, and finally certified back to the parent institution after completing his work, such certificate to be based on the work done and the proficiency made. In the case of individual students not connected with any institution, let each prove his capacity to profit by the opportunities, and then accredit him to the special officer who has charge of the field of work in which he may wish to study; on satisfactory completion of the work undertaken, the certificate of the Washington Memorial Institution might be addressed '*To whomsoever it may concern.*' Students working in Government laboratories, museums and libraries would be subject to the rules obtaining therein.

It is the belief of many acquainted with the educational system of the country that

the policy above outlined will result in a body of trained students, ready for expert work, many of whom will undoubtedly enter the government service, while others will become instructors in institutions of learning or be engaged as experts in private capacity. This will avoid competition with other institutions, will give most valuable training and practical experience to students, and will be especially helpful to instructors in educational institutions, who might wisely be sent for six months or a year to Washington, as at present some are sent abroad. There should be no thought of providing a general or liberal course of education. Coming as student assistants, there should be opportunities and encouragement only on clearly defined lines of study and investigation. There are many large and small problems to be worked out by the officers of the Washington Memorial Institution, but with the skilled educator and organizer now at its head as director their successful solution is only a matter of time. It is anticipated that the Washington Memorial Institution will, under the direction of Dr. Gilman, begin its work by November 1, 1901.

The Government's part in the work, when once under successful headway, will be to enlarge the quarters of the various bureaus concerned. This will be necessary eventually even if no student assistants are provided for. The Government has done its part nobly so far. It is now for the educational institutions of the country to come forward and assist by setting a high standard of scholarship for admission to the privilege of becoming a student assistant in the Government bureaus. Only students of the type of those who win fellowships or excel in ability should be certified or accepted.

The Washington Memorial Institution should, and I believe will, maintain a standard that will meet the approval of our colleges and universities. It should occupy a most important place in the great educational work of the country. With the hearty cooperation of our collegiate institutions and of the officers of the Government, there is little question that it will ultimately become the federated head and clearing-house of all the higher educational interests of the country.

The relations of the National Government to higher education and research are intimate and complex; but the complexities are already partially resolved, the present is auspicious, and the future outlook is most promising. Long ago the nation recognized its obligation 'to promote a higher and more extended policy than is embraced in the protection of the temporal interests and political rights of the individual.' The action of Congress in the present year in opening the Government bureaus at Washington for study and research is a long stride forward, and, if carried out in good faith must result in another and higher standard for American endeavor.

CHARLES D. WALCOTT.
U. S. GEOLOGICAL SURVEY.

THE ROYAL SOCIETY OF CANADA.

THE twentieth general meeting of the Royal Society of Canada was held in Ottawa, May 21, 22 and 23, 1901. This is essentially a national institution. It was founded in 1882 by the Marquis of Lorne, now His Grace the Duke of Argyll. The Society is divided into *four* sections:

I. French Literature, History and allied subjects.
II. English Literature, History and allied subjects.
III. Mathematical, Physical and Chemical Sciences.
IV. Geological and Biological Sciences.

The Society met this year under the presidency of Dr. Louis Honoré Fréchette, C.M.G., who delivered his inaugural address, 'Race and Language Problem in

Canada,' on the evening of Tuesday, May 21, before a large audience. The various sections met for the transaction of business and reading of papers. Delegates from affiliated literary, scientific and historical societies throughout Canada presented their reports and many of them took part in the deliberations of the Society.

The report of Council for 1901, presented by the Honorary Secretary, Sir John George Bourinot, K.C.M.G., historian, besides containing an account of the business affairs of the Society regarding the election of four new fellows, the diplomas of fellowship, the death of the Queen and the accession of King Edward VII., the associated societies and the proposed meeting in Toronto in 1902, dealt a heavy blow upon the circulation of 'yellow' journals of the United States and in general. The question of establishing public libraries, the care of the Dominion archives, the Canadian Marine Biological Station, Nova Scotian and New Brunswick archives, tidal investigations, together with the question of publishing historical memoirs and diaries received attention as well as the question of preservation of places of scenic and historic interest, including the site of Louisbourg and the Plains of Abraham. The report also contained biographical sketches of the late fellows, Hon. F. X. Marchand and Dr. George Mercer Dawson.

In accordance with a suggestion contained in the honorary secretary's report of last year, to prepare a record of Canadian publications embraced under the several sections of the Royal Society, the following committee of Section IV., which was appointed in May, 1900, reported, viz: For geology and paleontology, Dr. H. M. Ami; for general zoology, exclusive of entomology, Dr. J. F. Whiteaves; entomology, Dr. C. J. S. Bethune; botany, Dr. A. H. Mackay. By a resolution of the Section the same committee was reappointed for the year 1901.

Inasmuch as Sections I. and II. are literary and historical and Sections III. and IV. deal with the *sciences* mathematical, physical, chemical and natural, the following abstracts of papers read before the last two named sections will be given for the benefit of the readers of SCIENCE:

SECTION III.—MATHEMATICAL, PHYSICAL AND CHEMICAL SCIENCES.

Presidential Address: *A Century of Progress in Acoustics:* PRESIDENT LOUDON, of the University of Toronto.

The Principles at the Base of Quaternion Analysis: Professor ALFRED BAKER, M.A., of the University of Toronto.

Note on the Basic Chlorides of Lead, Antimony and Copper: Professor W. LASH MILLER, PH.D., of the University of Toronto, and Mr. F. B. KENRICK, PH.D.

A method of ascertaining whether the precipitate produced in a salt solution by potash or ammonia is a single chemical compound, a mixture, or a 'solid solution,' with results of experiments.

The Synchronism of Arctic and Antarctic Auroræ: Mr. ARTHUR HARVEY.

Auroral observations of the Belgian Antarctic expedition of 1898. Construction of a table and an auroral curve therefrom; identification of this curve with those for Canada and the United States. Enquiry from Arctowski, meteorologist of the *Belgica,* if other concordances are traceable between Auroræ Australes and Boreales. He entrusts the examination to Canada. Detailed scrutiny of the records of these countries shows the distribution of auroræ to be local and that their character varies at various points. Negative answers must be returned to the questions asked, but close examinations of auroræ in Canada must be made during the several Antarctic expeditions soon to set out.

The Human Machine, the Most Marvelous (as set forth by Dr. Lardner in his Animal Physics, 40 years ago): Mr. C. BAILLARGÉ, C.E., M.A.

On the Occurrence of Free Ammonia in Saline Waters: FRANK T. SHUTT, M.A., F.I.C., F.C.S.

The New Gas from Radium: Professor E. RUTHERFORD B.A. (Cantab.), of McGill University, and Miss H. T. BROOKS.

Discharge of Electricity from Glowing Bodies: Professor E. RUTHERFORD, of McGill University.

SECTION IV.—GEOLOGICAL AND BIOLOGICAL SCIENCES.

Observations on Phenological Records: Presidential Address before the Section by Dr. A. H. MACKAY, Superintendent of Education in Nova Scotia.

In this paper Dr. MacKay referred to the different stations established in Nova Scotia and other portions of Canada where phenological observations were being recorded. The records of the average phænocron of certain well-known species of flowering plants were also discussed, and the best methods of eliminating errors in records.

Sir John W. Dawson—In Memoriam: Professor FRANK D. ADAMS, M.E., Ph.D., (by request of the Royal Society at its meeting in 1900).

This memorial of the first president of the Royal Society of Canada was read by title and ordered to be printed *in extenso* together with Dr. Ami's completed 'List of Writings of Sir William Dawson.'

The Carboniferous Basin in New Brunswick: R. W. ELLS, LL.D., of the Geological Survey of Canada.

The Carboniferous rocks in New Brunswick embrace an area of not far from 12,000 square miles. They occur in a roughly triangular-shaped basin, which extends from the Gulf of St. Lawrence on the east as a base, nearly to the southwest boundary of the province. At a number of points beds of coal are found, but these, in so far as yet examined, are thin, ranging from a very few inches to about two feet in thickness. Borings have been made from time to time for over sixty years to ascertain the presence of thicker or more workable beds, but owing to various causes such attempts have not yet been successful. The greater portion of the area, however, has not yet been proved. The paper will briefly state some of the principal conclusions arrived at regarding the structure of this basin during the last thirty years, and will indicate the relations of the Carboniferous sediments to the rocks of the underlying formations. In the discussion which followed, Dr. Bailey pointed out that the Legislature of New Brunswick had granted a subsidy for the purpose of developing the coal-bearing areas of the Grand Lake District. Dr. Matthew maintained that there was considerable chance of discovering suitable coal seams in New Brunswick, and argued that something should be done to ascertain their possible existence. Dr. Ami stated that within the Carboniferous Basin of New Brunswick he would include the strata called 'fern-ledges,' Lancaster formation or 'Little River Group,' which held a flora and fauna of Carboniferous age.

Notes on Some of the Silurian and Devonian Formations of Eastern Canada, and their Faunas and Floras: H. M. AMI, M.A., D.Sc., F.G.S.

From recent studies carried on by the author, the succession of the sedimentary formations of both the Silurian and the Devonian Systems in Eastern Canada needs revision and elucidation. There are several distinct geological horizons which constitute as many distinct formations that are as yet unplaced and unnamed in the Canadian succession, and a discussion of the relations which exist between the different

formations or members of these systems in different portions of Canada was presented. The subdivision of the Silurian succession at Arisaig, in Antigonish County, Nova Scotia, those of Gaspé, Anticosti and Ontario are included, and are based upon the faunas determined by the late Mr. Billings and Professor Hall, as well as from material in the hands of the author for some years past. The subdivisions of typical Devonian formations are also given. These will form a basis for the classification of the terranes in eastern Canada, according to latest and most approved methods.

Acrothyra and Hyolithes—a comparison. With a description of a new species of Hyolithes: G. F. Matthew, LL.D.

The comparison was made for the purpose of seeing how far the muscular system of one genus corresponds to that of the other. The ventral valve of *Acrothyra* was compared with the tube of *Hyolithes*, and the dorsal valve of the former genus with the operculum of the latter. The *Hyolithes* described is a slender species from the base of the *Paradoxides* bed at St. John.

On some Modes of Occurrence of the Mineral Albertite: Professor L. W. Bailey, LL.D., of New Brunswick University.

Since the closing of the celebrated Albert Mines, in Albert county, New Brunswick, the ownership of which for a time hinged upon the determination of whether the mineral which thence derived its name should be regarded as coal or asphalt—a number of interesting observations have been accumulating which have a direct bearing upon this question. The present paper narrates and discusses some of these observations, and is accompanied by specimens illustrating the occurrence of the mineral with widely different associations, and in rocks of quite different geological horizons, *e. g.*, in Pre-Cambrian slates, in calcareo-bituminous shales, in gray Carboniferous sandstones, in snow alabaster, in admixtures of calcite and pyrite, and cementing crystals of selenite. The vein-like nature of the mineral and its originally fluid or semi-fluid condition are strongly emphasized. In the discussion which followed, Dr. Ells, Dr. Ami and Mr. Poole took part. Dr. Ells places the Albert shales in the Devonian System. Dr. Ami argued for the Eo-Carboniferous age as shown by fish remains and plants.

Jacques-Philippe Cornuti. Notes pour servir à l'histoire des sciences au Canada: Par Mgr. Laflamme.

Cornuti a publié à Paris, en 1635, un volume qui renferme la description d'un bon nombre de plantes canadiennes. Il n'est jamais venu au Canada; ses études ont été faites d'après des échantillons vivant dans le jardin des Robins, à Paris. Le but de cette note est d'abord de rechercher par qui les plantes canadiennes avaient été transportées à Paris, si tôt après la fondation de Québec, et ensuite, d'examiner toutes ces descriptions et de déterminer la synonimie entre la nomenclature de Cornuti et la nomenclature actuelle.

On some Geological Correlations in New Brunswick: Professor Bailey, LL.D., of New Brunswick University.

While the geological age of the rock formations in New Brunswick has in most instances been determined upon satisfactory evidence, much uncertainty has existed regarding certain groups of strata and especially those which, consisting largely of slaty rocks, border the great central granite axis which traverses the central part of the province, in the counties of York, Carleton, Northumberland and Gloucester. For, though regarded originally as Cambrian by Gesner, Robb, Logan, Hind and others, and subsequently colored and described, though only provisionally in the maps and reports of the Geological Survey, as Cambro-

Silurian, the only fossils found therein, at widely separated points, were, with a single exception, where an Ordovician fauna occurs, such as to indicate a much more recent (Silurian or Devonian) horizon. In the investigation of the problems arising from this fact, and in the effort to determine, upon behalf of the Geological Survey, more exact knowledge as to what systems were actually present and their relative limits, the author of this paper was, during the past summer, fortunate in being able to obtain evidence in the discovery of certain graptolitic strata, tending to confirm the original view that large portions of the belts in question are really of Cambrian age, with a probability that other large areas are still older, representing either the Etcheminian formation, so called, of Matthew or the Huronian of other writers. The facts relating to these observations, which have a bearing upon questions of a far-reaching character in relation to Acadian geology, are in this paper briefly summarized and discussed.

On the Subdivisions of the Cambrian System in Canada: H. M. AMI, M.A., D.Sc., F.G.S., of the Geological Survey of Canada.

This paper discusses the various geological formations which naturally fall under the Cambrian system in British North America. An attempt is made to present a systematic table giving the succession of the different faunas of this system and the different formations under which each falls. The main object of this paper is to bring the nomenclature of this system to date with a view of classifying the organic remains comprised within its limits, with a brief discussion as to these limits.

A Backward Step in Paleobotany: G. F. MATTHEW, LL.D.

This is a review of the attempt made to claim the plant beds in the Little River Group and their flora, and so the whole terrane, as Carboniferous. This claim is made on Paleobotanical grounds by Messrs. D. White, R. Kidston and H. M. Ami.

The article recites the stratigraphical and physical objections to this view, and in this connection two sections near St. John are given, showing the relation of this terrane to the lower Carboniferous. The fauna of the plant beds is reviewed, and it is suggested that even from this point of view there is not sufficient evidence to overthrow the result arrived at by those who had previously studied the flora and the stratigraphy. Dr. Bailey, Dr. Ells, Mr. H. S. Poole and Dr. Ami took part in the discussion which followed the reading of this paper. The first three gentlemen brought forth all the arguments possible bearing on the Devonian age of the plant beds in question. Dr. Ami pointed out the synchronism existing between these beds and the Carboniferous strata of other parts of North America and Europe.

Notes on Some Butterflies from Western Canada: Dr. JAMES FLETCHER, Dominion Entomologist.

This paper described interesting captures made in the northwest Territories and the Rocky Mountain region of Canada.

The Avifauna of the Province of Quebec: Sir JAMES M. LEMOINE, Knt. F.R.S.C.

This forms an interesting check-list of the birds of the Province of Quebec.

A Dual Classification required in the Nomenclature of the Geological Formations in Different Systems in Canada: H. M. AMI, of the Geological Survey of Canada.

This paper brings forward the result of special work carried on by the writer during the past fifteen years in the classification of numerous geological formations throughout the Paleozoic Period in Eastern Canada. It has become necessary, in the light of recent investigation, to introduce two parallel columns at least, in the suc-

cession of the geological formations of Ordovician, Silurian, Devonian and even Carboniferous Systems. Tables giving the natural order of succession of the different formations falling under this dual classification accompany the paper.

The Value of Nature Study in Practical Education: Dr. James Fletcher, Dominion Entomologist to the Central Experimental Station at Ottawa.

In his opening remarks Dr. Fletcher said that he was thankful that the educators of the youth in every province of Canada have shown that they keenly appreciate the value of natural history studies as an integral and effective part of a practical education. He would appeal more especially, now, to the educated classes of Canada, amongst whom it must be acknowledged there is an appalling and unnecessary ignorance upon many useful branches of knowledge, some information upon which would make them far better citizens and more efficient competitors in whatever branch of work they may have adopted as the means of obtaining a livelihood. There is no profession, trade or occupation, in which definite or exact knowledge is not daily required with regard to subjects, the consideration of which comes within the scope of some branch of natural science. The last half-decade has seen a bright awakening to the realization of the value of nature studies as a means of cultivating the faculties of the youth of every land where progress is made. To teach the child the beginnings of things, the elements of knowledge through the common things about us, will lead it to want to see, to know and understand, and hence think carefully with a view of drawing right conclusions. The flowers, birds and insects furnish as many and useful objects for the grandest, the simplest and best lessons in educating the youth of our land. Whether they are beneficial or injurious, and why so, will lead the observing student to find out their uses and recognize whether they have or have not as yet been recognized. Sympathy and kindness are the outcome of nature studies, likewise healthful enjoyment. Principles of perfection appear wherever nature has not been interfered with. A perfect method and system is revealed, and well may those entrusted with the education of others turn to these natural models to inculcate those principles so necessary to develop the mind.

Amongst the interesting exhibits shown during the meetings of the Royal Society was a plan of the new museum, known as the 'Victoria Memorial Museum,' to be erected in Ottawa at once. Through the kindness and courtesy of the Honorable Mr. Tarte, Minister of Public Works, the plans were placed on exhibition in the Normal School building where the Royal Society was holding its meetings. The building has a frontage of 322 feet, and is 188 feet deep, with a tower dome in the center. It is intended to accommodate the collections at present stored in the unsafe building occupied by the Geological Survey Department on Sussex Street, Ottawa, comprising minerals, ores, fossils, plants, trees and other natural history objects as specimens illustrating the natural resources of Canada, also the Fishery exhibit now on O'Connor Street, and the paintings in the Art Gallery. A resolution, passed by the Royal Society of Canada and transmitted to the Government of Canada congratulated the latter on its wise action.

On May 22 a resolution was passed approving and supporting Capt. F. Bernier, of Quebec City, who is taking charge of the expedition to the North Pole. An interesting discussion followed in which many Fellows took part, including G. H. Parkin, C.M.G., Sir Sandford Fleming Dr. R. Bell,

F.R.S. and Capt. Bernier himself. It will be remembered that in 1900 the last-named gentleman described his proposed route of travel after having pointed the courses taken by all the previous important expeditions to the North Pole, including Fridtjof Nansen's important last voyage.

The following officers were elected:

President: Principal J. Loudon, LL.D., of Toronto University, Toronto.

Vice-President: Sir James A. Grant, K.C.M.G., M.D., etc., Ottawa.

Hon. Secretary: Sir John G. Bourinot, K.C.M.G., LL.D.

Hon. Treasurer: Dr. James Fletcher, F.L.S.

The following officers of Section IV. (Geology and Biology) were elected for the ensuing year:

President: Professor Frank D. Adams, M.Sc., Ph.D.

Vice-President: Professor T. Wesley Mills, M.D., etc.

Secretary: Mr. G. U. Hay, Ph.B. (St. John, N.B.).

H. M. AMI.

OTTAWA, May 27, 1901.

---

*SCIENCE AND THE LONDON UNIVERSITY.**

I.

BY the University of London Act, 1898, and the statutes and regulations framed in pursuance thereof, the long-standing controversy as to the form and organization of the London University was finally disposed of. The various colleges and other institutions doing university work within the metropolitan area have been coordinated under a strong and representative senate, which is charged with the duty of providing, for the six millions of inhabitants within a radius of 30 miles from the University building, every kind of instruction of university type. To enable the reorganized London University to cope with this gigantic task, the Chancellor of the Exchequer frankly confesses his inability to do more than provide the office expenses. If London wants a teaching university, London, says the Chancellor, must pay for it. In the special financial circumstances of the moment this appeal to public-spirited Londoners can scarcely be considered unreasonable.

* From the London *Times*.

The task of equipping and endowing a University can never be a small one, and the extent and variety of the needs of London might daunt the munificence even of an American millionaire. Fortunately, we do not have to start quite from the beginning. The organization and constitutional framework are completed and stand ready to start. A large part of the materials for a University worthy even of the capital of the Empire only await the hand of the master builder. What is wanted is, first, a comprehensive survey of the field and an appreciation of the amount and variety of the work to be done. Upon this must follow the motive power of money.

The new university is organized in eight faculties, namely, theology, arts, music, law, medicine, science, engineering and 'economics and political science (including commerce and industry).' But, though provision is thus made for all branches of University study, old and new, it is already clear that London University will have a character of its own. The distinctive note of the University is evidently destined to be that of applied science, or the concrete application to every branch of industrial and social life of the discoveries and laws of the various sciences. It is this side of university organization that we must therefore first consider.

In physical science the London University holds an honorable tradition, as having been the first to create a science degree. At present the University includes three 'schools' of science for men, and two more (Bedford and Halloway) for women only. Of these, the Royal College of Science, fully

staffed and equipped at the Government expense, is confined practically to science teachers, drawn by scholarships from all parts of the country, and to the mining and metallurgical students of what was formerly the Royal School of Mines. The science schools at University and King's Colleges, directed by able professors, are severely handicapped by inadequate accommodation and limited funds, whilst the high fees necessitated by the absence of endowment exclude all but a small number of students. The total number of undergraduate science students in these five schools may be estimated at six or seven hundred. Cheaper science-teaching at more convenient centers, open in the evening as well as in the daytime, is supplied not only at the admirably organized Finsbury Technical College of the City and Guilds Institute, but also by the dozen so-called 'polytechnics.' These latter have been greatly improved during the last few years. By the aid of large grants from the London County Council, their laboratories and scientific equipment have been brought up to a high university standard, whilst the professional staff has been strengthened by the appointment of men of excellent scientific attainments. A large proportion of London candidates for science degrees are now trained in the polytechnic laboratories, which may probably include, in the aggregate, between two and three hundred science students above matriculation standard. The total number of science students of undergraduate status in the whole six million of people apparently does not reach one thousand. Additional centers of science instruction for undergraduates are required in north west London, Hackney and Hammersmith, whilst in the outer suburbs the existing institutions at Croydon, Tottenham and West Ham need developing up to university standard. With additional professors and enlarged laboratories at these twenty-five science centers, all parts of London would be fairly well served, so far as science instruction up to the B.Sc. degree is concerned; and the number of undergraduate students in the faculty might reasonably be expected to rise to at least 2,000.

But the most serious deficiency in the London faculty of science is not the inadequacy of the instruction for the science degree, but the lack of anything like adequate provision for chemical, physical and biological technology, or the application of science to industrial processes. The munificence of Mr. Ludwig Mond has provided a well-equipped laboratory at the Royal Institution, in which a few highly qualified scientists find the opportunity for pursuing special researches. But of public provision for instruction in scientific technology there is practically none. The same national neglect which lost us the great industry of coal-tar products—positively a British discovery that we failed to utilize and abandoned to Germany—now bids fair to lose us one branch of applied chemistry after another. At the present moment perhaps the most promising outlook in the scientific field is presented by electro-chemistry, including both electrolysis and the multifarious operations of the electric furnace. This new science has already transformed the commercial production of copper and aluminum, and given us such new products as carbide of calcium (for the economical production of acetylene) and carborundum. It bids fair, moreover, to revolutionize the whole alkali industry. Yet beyond certain small experiments, due to personal initiative of two or three professors, London offers no means and no opportunities for instruction and research in the subject. If electro-chemistry is destined to transform the world's industry, it is to Germany, and not to England, that the advantage of the first start seems at present likely to accrue. There is no more press-

ing need in London's University equipment than a special school of electro-chemistry, fully equipped with its necessary expensive apparatus, and provided with an endowed and not overworked staff of professors, able to inspire and direct the studies and researches of a selected band of graduate students. The same deficiency is found in other branches of technology. Mining and metallurgy are provided for on what must be called a small scale at the Royal College of Science, and mineralogy also in two or three small classes elsewhere. But nothing that can be called adequate exists for the technical education, at convenient centers and hours, at low fees, of the swarm of mining and metallurgical engineers that London ought to be sending out to every part of the Empire. It deserves the attention of those who are interested in the great mining enterprises of South and West Africa, America and Australasia, whether the time has not come for the establishment of a distinct school of metallurgy and mining, with special reference, not to coal and iron and the conditions of Great Britain, but to the products and needs of other climes. In applied chemistry, too, beyond the praiseworthy attempt at the Herold's Institute (Bermondsey) to deal with leather dyeing and tanning, practically nothing in the nature of a school of chemical technology exists in the metropolis. London transcends every other city in the magnitude and variety of the local industries depending on one chemical process or another. Besides its large interest in every branch of the clothing trade, in all the materials for construction, and in such specialties as the use of india rubber, London is the greatest center for all the applications of photography and the various lithographic processes still most incompletely taught and studied. It is, moreover, the largest center of gas manufacture, and hence the most extensive producer of coal-tar. At present the valuable by-products of London's gas works are for the most part only so far dealt with on the spot as to reduce the cost of their freight to other parts. Practically all the skilled and remunerative treatment of coal-tar products is left to Germany, to which country we export what is virtually the raw material of a most valuable trade, from sheer lack of scientific knowledge of how to make the most of it. Apparently we are contented with this state of things, seeing that London has to this day no center of instruction in gas manufacture and the treatment of its by-products; nor any provision for systematic research into their possible developments. Even the immemorial London industry of tanning is falling behind. Hides are positively beginning to be exported from England to New York to be tanned in the United States by new processes and sent back as leather to Leicester and Northampton. It is probable that few, if any, investments would, in the largest sense, pay better than the establishment — possibly in east or south London—of a great school of chemical technology; and, if we turn from physics and chemistry to biology, we must notice that, whilst the Institute of Preventive Medicine studies bacteriology from the pathological standpoint, London has as yet no provision for instruction and research in its industrial side. One of the largest and most profitable of London industries depends on the bacteriological process of fermentation. The whole future of London's food supply—to say nothing of its sewage disposal—is involved in the same question; and refrigeration, to name only one out of many applications, is already the nucleus of a great industry. The most economical means of lowering temperature on a large scale, under commercial conditions, has become literally a matter of life or death in certain industries. This knowledge can hardly be 'picked up' at the works or in the office.

Yet there is no institution teaching it. We need to expand our few and scanty classes in zoology and physiology into an organized school of instruction and research into all the biological processes that are or can be applied to industry. We pass to another range of science in mathematics and astronomy; but it is one in which London has a special interest. It seems almost incredible that in the greatest port of the world, providing its own large quota to our mercantile marine, absolutely no public provision exists for instruction in the art of navigation, or in the application of mathematics and astronomy on which the art depends. There is urgent need for the establishment, in connection with the University, preferably in East London, of a school of nautical astronomy and navigation, including the applications of magnetism and meteorology to the sailor's art.

The Science Faculty seems thus to require:

1. Increase in staff of professors and instructors at existing centers—say, £15,000 a year (£500,000).

2. Extensions at existing centers in buildings and equipment to accommodate additional students—say, £80,000.

3. New centers — building, equipment, and endowment of science departments at, say, three at £40,000 (£120,000).

4. New subjects—provision for buildings, equipment, and endowment of centers for electro-chemistry (£100,000), mining and metallurgy (£100,000), technological chemistry (£100,000), bacteriology and biology in its industrial relations (£100,000), nautical astronomy and navigation (£100,000), etc.—total for science, £1,200,000.

SCIENTIFIC BOOKS.

Lehrbuch der vergleichenden mikroskopischen Anatomie der Wirbelthiere. By DR. ALBERT OPPEL. Dritter Theil. Mundhöhle, Bauschspeicheldrüse und Leber. Jena, Fischer. 1900.

With this volume is completed the discussion of the digestive system. Volume I. comprised the stomach and included 543 pages; Volume II., the esophagus and intestine, in 682 pages. The present volume consists of 1180 pages, with XI. plates and 679 figures in the text, therefore exceeding considerably the preceding volumes in size in accordance with the greater complexity of the parts considered.

The work follows closely the plan of the preceding volumes. Each subdivision is discussed in historical sequence, the statements of the author being included between oblique lines, //. In accordance with the plan, the greatest pains have been taken to show the present state of knowledge of the structure of each part in the different forms, and to this end the search in the literature has been made exhaustive, and references to all papers, however trivial, have been sought out. No prejudice has influenced the writer in favor of continental investigators to the exclusion of others; indeed, the recognition of American work seems to be greater than that accorded by many American writers. The quotation of each author is followed by his name and the year of publication. The complete title is given in a bibliography in the end of the volume.

Where there are differences of interpretation (as, *e.g.*, as to the nature of the demilunes in the mucous salivary glands), the different theories are propounded, weighed and (where possible) some choice is indicated.

The text is followed by a table of animal forms, giving a key to the position of the species considered in the text and an arrangement of their families in systematic order. This is followed by the bibliography of 50 pages, and finally, author and subject indices.

In the body of the work the oral cavity with its adnexa, pancreas and liver are taken up successively. In connection with the oral cavity are discussed: the structure of the mucous membrane in the different classes; the pharynx of mammals; the lymphoid tissue of the oral cavity; the tongue; nerves and sense-organs; and finally, the oral (salivary) glands. The teeth, which on many accounts might seem to be properly included, are omitted to be discussed with the skeletal system in a subsequent volume.

In each of the subdivisions the subject is taken up systematically and in detail. For example: the lymphoid tissue in the oral cavity is discussed (1) as to its significance, (2) the migration of the leucocytes through the epithelium, (3) the structure of the lymphatic nodules, (4) the tonsils (lingual, palatine and pharyngeal), and finally (5) the development of the tonsils. In summarizing the subdivision dealing with the tongue, Oppel arrives at the conclusion that the mammalian tongue is to be derived from the entire tongue of the lower vertebrates and not merely from the back portion of it (as Gegenbaur believed).

Especially in the case of the oral (salivary) glands has there been felt the need of a summarization of knowledge, and Oppel has furnished it admirably. The classification of the mammalian oral glands, their occurrence and structure in the different animals, have been made the subject of varied interpretations—Lavdowsky's, Klein's, Nadler's, Stöhr's and Ranvier's are given.

The interpretation of the demilunes of Giannuzzi of the mucous glands receives full discussion. The three views of the substitution theory, phase theory and special function theory are each presented and criticised. Oppel rejects the first two and considers the third as the one to be accepted in the light of recent work (Krause, Solger, Müller, *et al.*).

The pancreas seems to be of universal occurrence in the vertebrates; wherever it has been sought for it has been found. Comparison with the salivary glands to see whether it can be regarded as an 'abdominal salivary gland' (the German name) shows that there are certain specific structural differences that distinguish it.

The pancreas is discussed from the point of view of the finer structure of the gland cells, including a consideration of the so-called paranucleus, the activity of the cells, the form of the tubules, centro-acinar cells, the terminal ducts and the structure of the pancreatic ducts in the classes of vertebrates, the connective tissue of the gland. The interesting areas of Langerhans are next discussed, and in regard to their occurrence and significance, Oppel says that they have been demonstrated in most vertebrates (doubtfully in the Selachia). He regards them as permanent structures and not transitory (as developing acini) and considers them of epithelial (entodermal) origin. On the other hand, whether or not they elaborate an internal secretion, he dares not decide, but should this be found to be the case, it does not, he thinks, militate against the view that they were originally part of the gland proper giving (possibly) a clue to the structure of the primitive gland. Blood vessels and nerves are considered next. The question of the occurrence of an accessory pancreas is then discussed. The development of the pancreas in the various vertebrate forms closes the chapter and is supplemented by a helpful table showing and comparing the mode of development in the different vertebrates as ascertained by the different workers.

In dealing with the various structures no attempt is made to discuss the gross anatomy as beyond the scope of the work, save in so far as necessary, though often—as in the case of the liver—references are given to the sources whence such information may be gained. It is likewise in accordance with the plan of the work to present the discussion in historical sequence, so that the liver is considered from the standpoint of (*a*) the liver lobule, and (*b*) the liver cell and gall capillaries, despite the fact that liver lobules are peculiar to mammals.

In the consideration of the remaining structural features of the liver, bile-duct and gall bladder are taken up, followed by a discussion of the liver in the different vertebrates. The development of the organ constitutes the closing division. Few original observations or generalizations are made in this portion of the work.

The comparison of the liver with other typical glands receives considerable attention, together with the question of the anastomosis of the gall-capillaries, and the conclusion is reached that a net-like arrangement of the gall capillaries occurs in the lower vertebrates, and in the higher forms at least in early development. Under the subdivision dealing with the functional activity of liver cells, the glycogen, pigment and fat content are discussed. Most investigators agree that there are two kinds of

liver cells, but there is no answer to the meaning of the differences.

The work as a whole is a valuable treasure-house of knowledge that will save both investigator and student much time and labor. The author does not state which system will form the subject of the next volume, nor when we may expect it to appear. At the same rapid rate of work it will be due in 1902, and we feel sure that the same excellence will be maintained.

B. F. Kingsbury.

RIVER PROFILES.

An interesting and valuable publication of the Department of Hydrography of the U. S. Geological Survey on the profiles of rivers in the United States, by Henry Gannett, has just been published and is now available for distribution. It embodies within a hundred pages the leading facts of about one hundred and fifty of the most important rivers and streams of the country, noting their length, drainage area, the location of water power in their courses, their peculiarities of flow and the nature of their drainage basins.

The rivers selected are those which are the largest in size and bear most directly upon the varied interests of the country such as the Connecticut, Hudson, Susquehanna, Ohio, Potomac, Mississippi, Missouri, Platte, Colorado, Sacramento, Columbia and others. The figures for the table showing the height above sea-level and fall per mile were collected from various sources. Some were obtained from the report of the chief engineer of the U. S. Army, some from railroad companies when their lines cross the streams and some from the atlas sheets of the U. S. Geological Survey. In the case of such rivers as the Connecticut, Susquehanna, Mississippi and Colorado, where the surrounding country is in part or whole of peculiar physiographic interest, very excellent and vivid descriptions of its leading physical characteristics are given, which add to the interest, and render it valuable from an educational standpoint in geographic and physiographic instruction. The pamphlet is the result of much careful work and is the first attempt to collect and compile this information in its present form.

SOCIETIES AND ACADEMIES.

ZOOLOGICAL CLUB, UNIVERSITY OF CHICAGO. WINTER QUARTER, 1901.

I.

The first meeting of the quarter on Jan. 9 was devoted to a paper by Professor F. R. Lillie, entitled 'A Comparison of the Power of Regeneration in Three Genera of Planarians, viz., *Planaria*, *Phagocata* and *Dendrocœlum*.' The following is an abstract of the paper:

"The greater part of the large volume of recent work on regeneration of planarians has been carried out on a single genus, *Planaria*. Attention should be called to the importance of the comparative method in studies of this kind. This may be illustrated by some results of observations on two other genera, *Phagocata* and *Dendrocœlum*. These three genera are found living together in a single pond in Falmouth, Mass. *Planaria* is especially abundant in this pond, in some parts of which as many as twenty or thirty individuals may be found on the under surface of a single large stone. Scattered about among these individuals one finds usually from one-half to one-third this number of individuals of *Phagocata* and two or three specimens of *Dendrocœlum*. *Planaria* is thus much more abundant than *Phagocata* and the latter than *Dendrocœlum*. The last is more abundant relatively in portions of the pond where there is a large amount of vegetation growing on the bottom. The habits of life of the three genera in question are, however, very similar.

"*Phagocata* was found to resemble *Planaria* very closely both in the modes of, and capacity for, regeneration. *Dendrocœlum*, however, offers the greatest contrast to both *Planaria* and *Phagocata*. The first experiment was to cut a single specimen in half through the pharynx. The cut surfaces healed and the farther fate of the parts was as follows: The posterior part formed no new tissues, although it lived for some days; from the anterior part, on the other hand, there grew out a pointed piece, which acquired the characters of a tail. Two weeks after the operation this piece also died without any extensive remodeling of the whole having taken place. I afterwards repeated the ex-

periment several times with a similar result. Thinking that the failure to regenerate a head might be due to the presence of the pharyngeal pouch, I then cut fourteen specimens transversely behind the pharynx. Two days after the operation an interesting difference in the reactions of the anterior and posterior parts was noticeable. While the former reacted in all respects like normal individuals, the latter showed no definite reactions of any sort but remained scattered over the bottom, some with the ventral surface up. In six days all the posterior pieces were dead without having shown any signs of regeneration, while all the anterior pieces, kept in the same dish, were living and regenerating new tails. This experiment was afterwards repeated with similar results, and I soon became convinced that, in this form, while a tail might regenerate at any place from the pharynx back, a new head could not be formed in this region of the body.

"The question was now, could a new head be regenerated in front of the pharynx? So specimens were cut in two immediately in front of the pharynx. The result of these experiments was that, while a very narrow border of new tissue might be formed at the cut border of the posterior piece, there was never any regeneration of even the semblance of a head. The anterior pieces, on the other hand, regenerated a new tail as before, and also a new pharynx.

"In the next experiment the heads of five individuals were removed by a transverse cut just behind the eyes. The heads did not regenerate, but in five days it was apparent that the decapitated pieces were regenerating new heads; in one piece the eyes could already be seen. On the next day eyes had appeared in all. The capacity for regeneration of a head was thus demonstrated.

"Two questions now remained: Was the regeneration of a new head due to the size of the piece, or to the position of the cut? and how far back does the capacity for regeneration of a head extend? The first question received a very simple answer; the head was first cut off just back of the eyes, and then from the anterior end of the major piece a small transverse piece was cut. In six days a rudimentary head with eyes developed on the front end of the small piece in one of three specimens.

"How far back does the capacity for regeneration of a head extend? We have seen that it cannot be formed from tissue just in front of the pharynx, but that it can be formed just back of the eyes. Twelve specimens were cut transversely about half way between the front end of the pharynx and the anterior end of the body. The reactions of both parts were perfectly normal, though the headless parts reacted much less rapidly than the parts with heads. In seven days both parts were rapidly regenerating and eyes had appeared in the headless parts; in the head-bearing parts the new pharynx was regenerating in the new tail. Both kinds of parts then completed the regeneration rapidly, though even after nineteen days the normal proportions were not restored.

"Thus in *Dendrocœlum* new tissue may grow out in the form of a tail at any transverse level of the body, excepting only the most anterior part to a very short distance back of the eyes; the capacity for regeneration of a head, however, is limited to the anterior third or fourth of the body. I do not mean to assert that the formation of a new head back of this level is completely impossible. Some one may at any time demonstrate, by taking suitable precautions, that a new head may be formed back of this level. But it is shown very clearly by these experiments that the power of regenerating a new head is largely, if not entirely, confined to the prepharyngeal part of the body in *Dendrocœlum*, and that it is always greater at any more anterior transverse level.

"Thus it is demonstrated that in *Dendrocœlum*: (1) The power of regenerating a head is limited to a small part of the body. (2) That a new tail may be generated at any transverse level. (3) That the capacity for remolding degenerating parts into normal proportions is very limited. (Limitation of 'morpholaxis,' Morgan.) (4) That there is a relation between the power of regeneration in this form and the power of performing the usual coordinated movements, the latter power always being slight in parts incapable of regeneration. This

last fact leads me to think that the nervous system plays an important part in regeneration of planarians. A paper, soon to appear, will deal more fully with these facts and the interpretation of them."

At the second session of the Club, held on January 23, Miss Elizabeth Meek gave the results of a statistical study of variation in the mandibles of the stony-beetle. An abstract of this paper has already appeared in Vol. XIII. of SCIENCE.

C. M. CHILD,
Secretary.

TORREY BOTANICAL CLUB.

AT the meeting of the Club on May 14, 1901, the scientific program was as follows: Professor Underwood spoke on 'The Genus *Pteridium*,' the type of which is the widely distributed and well known *Pteris aquilina* of Linnæus. It was separated from the genus *Pteris* by Gleditsch in 1751, followed by Scopoli in 1760. The principal generic character as distinguished from *Pteris* is the presence of a double indusium. Specimens of various species, varieties, and forms were shown, including extremely large specimens of *Pteridium aquilinum* collected by the speaker in southern France. Three species may be recognized in North America. The first of these is the common and variable *Pteridium aquilinum*, of which the recently described variety *pseudocaudatum* Clute is more or less common from New Jersey southward. The second species is *Pt. caudatum*, found in the extreme tropical of Florida. The third, which occurs in the West Indies, seems to be identical with a species originally described from Brazil, though it has been confused with a species from the Society Islands. Species from South Africa, India, and the Hawaiian Islands were also mentioned.

Dr. D. T. MacDougal gave an account of 'Carpotropic Movements of Flowers,' taking his illustrations from plants in bloom at the time. The two classes of movements of flowers are the induced or protective and the developmental or automatic. Of the former, the wild carrot furnishes a good example, its umbels being erect during the day and pendent or inverted at night. The segments of the perianth of the tulip also furnish a good illustration of movements induced by changing conditions of temperature.

Developmental movements, *i. e.*, those due to forces which originate within the plant, are well shown in the inflorescence of *Allium Neapolitanum*. The inflorescence here is nodding when in the bud, but the development of the flowers sends a stimulus to the curved portion of the peduncle, causing it to straighten. In addition, the plant is provided against accident by the fact that each pedicel has the power of independent movement. Each pedicel will bend so as to erect the flower if the peduncle is prevented from straightening. Under normal conditions the pedicels take positions separating the flowers equally. In *Claytonia Virginica* the buds are nodding, the flowers erect. After fertilization, there is another curvature, more abrupt and nearer the base of the pedicel. In *Streptocarpus*, the flower-stalk is curved and somewhat coiled in the bud, while the open flower is horizontal, bending the stalk at a right angle, and after fertilization the maturing fruit becomes erect. The movements of the fruit, in many cases at least, are for the better dissemination of the seeds, and the movements of the flower are commonly connected with methods of fertilization. Dr. MacDougal referred also to the curious development of the cotyledons in *Streptocarpus*. One of the cotyledons ceases to grow after a time, while the other elongates very much. In one species, this cotyledon remains the only foliage of the plant.

Dr. N. L. Britton gave an account of 'An Undescribed Species of *Stachys*.' He remarked that many North American species were until a few years ago referred to the *Stachys palustris* of Europe, but have more recently been recognized as distinct. A plant which grows on the sand hills along the beach near New Dorp, Staten Island, is really very different from the European *S. palustris*, and may safely be considered a new species. It has been collected in Michigan by Mr. Farwell and a specimen from Illinois is in the Chapman Herbarium. The species is apparently confined to sandy shores.

M. A. HOWE,
Secretary pro tem.

THE MINNESOTA ACADEMY OF NATURAL SCIENCES.

THE April meeting of the Academy, which proved to be a very interesting one, was addressed by Mr. F. K. Butters, who spoke on the 'Fungus Flora of Minnesota.' The more fundamental relationships of the fungi were illustrated by slides, taken from Engler and Prantl's 'Pflanzenfamilien,' and also by original microphotographs of common minute Phycomycetes and Ascomycetes, as well as by a large number of photographs of the fleshy fungi of the locality, taken in the field to show their natural conditions of growth.

The speaker pointed out that the fungi are to be considered as one of the most successful groups of the plants, showed by their diversity of form, the great variety of conditions under which they will grow and their numerical importance. In Minnesota the number of species is probably in excess of the flowering plants. The diverse conditions under which fungi will grow, *e. g.*, in water, upon living plants and animals, on decaying organic substances, in humus and in sand containing a minimum amount of organic matter was illustrated. Attention was called to the fact that on account of the great number of spores produced wherever there is suitable environment there also will be numbers of plants. The diverse forms of fungi are modifications of a few types to be regarded as distinct phylla and parallel lines of development sometimes exist in different groups.

The lecture was productive of a very general discussion of local fungi and was greatly enjoyed by the large audience present.

F. G. WARVELLE.

DISCUSSION AND CORRESPONDENCE.

GEOLOGY OF CHINA.

TO THE EDITOR OF SCIENCE: In the discussion in the last number of SCIENCE of my article in *McClure's Magazine*, there are some things which deserve attention in order to get the facts fairly before the public.

1. It is proper for me to state that the title of the paper and the headlines were put in by the editors; so that I was in no sense responsible for them. I think that in the article itself there are no offensive claims to original discovery.

2. The quotation from Geikie's 'Great Ice Age' (p. 699) is unfortunate for my critic, since it was that very quotation which misled me during a considerable portion of my trip. In this quotation Geikie says, "Its materials [those of the loess], we may believe, are largely of *fluvio-glacial* origin, and represent in great measure the flood-loams swept down from the mountains and plateaux when these supported extensive snow-fields and glaciers. But, as Baron Richthofen in his great book on China has demonstrated, the loess, as we now see it, owes its structure and heaping up to the action of the wind, and is even now forming and accumulating in many regions of Asia. It is, in short, a true steppe-formation." On page 697 Geikie had said, "According to Przevalski, undoubted traces of former glaciation are seen in the Suma-Hada range, west of Kalgan in China." My first point was to visit this mountainous region west of Kalgan supposed both by the Russian and by Geikie to be the source of the loess in Eastern China. But we found no indications of glaciation in that region, and pursued our investigations sufficiently to convince us that there were none; so that Geikie's theory of the 'fluvio-glacial origin' of the loess falls to the ground in that region. That came pretty near being a discovery.

3. On the same page Geikie says, "Kropotkin's researches have led him to conclude that the whole of the upper plateau of Asia and its border-ridges were under a mighty ice-cap." Assuming the truth of these statements, Geikie says upon the next page, "The mountain-valleys everywhere contain wide and thick sheets of rounded blocks, and coarse and fine gravel, which are in every respect comparable to the fluvio-glacial gravels of the Alps. But in none of the descriptions of these which I have read is there any clear indication as to whether the deposits occur in successive terraces like the high- and low-level terrace gravels of the Alpine lands of Europe. Something like this arrangement seems to be present in the valleys of the Thian Shan, and may possibly refer to recurrent phases of glaciation." In accordance

with this view, the glacial map of Asia which precedes the chapter is covered with extensive glaciated areas over the regions which I have specifically visited. All of which shows the confusion of mind which has widely prevailed up to the present time concerning the glacial conditions of Southern Siberia and Central Asia, and goes to justify the editor in naming my article.

4. I am not aware that Kropotkin had any personal knowledge of the southeastern border of West Turkestan. But it is significant that Geikie, on his authority, speaks of 'immense sheets and terraces of loess' fringing the base of its mountainous border. The writer in Science assumes, as I believe unwarrantably, that the only indication of a former sea-level is the occurrence of sea shells. On the contrary, in the broader studies of physical geography that are now current, sea-levels may be determined in many places by terraces where shells are not present.

5. With reference to the occurrence of the bones of land animals and of terrestrial mollusks in the loess, I need only to say, that the great uncertainty concerning the situation of these remains with reference to the original deposit largely, if it does not entirely, breaks the force of the argument which is drawn from it. No one will deny that the wind has in many instances redeposited vast amounts of loess, nor that subsequent streams have done the same. But to go no farther than our own country, it is difficult for any one who is familiar with the situation of the loess over Northern Missouri, for instance, or in the center of the Mississippi Valley at Vicksburg, to believe that it has been deposited either by the wind or by flowing streams of water when the land stood at its present level.

In due time I hope to bring the facts in fuller detail before the public. But this much I may confidently say, that the whole problem of the loess has not yet been fully comprehended, much less has it been solved. If the renewed discussion elicited by my report shall contribute to an understanding of the subject, a great point will be gained. But I am sure that the as yet little understood facts of Central Asia will contribute much toward a solution of what has been one of the most perplexing of all the geological problems.

G. Frederick Wright.

'THE LARYNX AS AN INSTRUMENT OF MUSIC.'

To the Editor of Science: Noting in your issue of May 24, a communication from Arthur Gordon Webster quoting Professor Le Conte's reference to the larnyx, comparing it in its function to a horn and citing a passage from Helmholtz containing the same comparison, I am tempted to refer your readers to a much earlier example of the same conception. I quote the following from some notes of mine: "In 1700 Dodart ('Memoire sur les causes de la voix de l'homme,' par M. Dodart, *Memoire de l'Academie des Sciences*, 1700, p. 238) insisted that the trachea only furnishes the material of the voice, *i. e.*, the expired air. The glottis is the only organ of the voice. All the effects of the glottis for tones depend on the tension of its lips, and of its various internal structures. The concavity of the mouth has no part in the production of the voice, but it is a modifier of it, and still more is this true of the nose. He showed that Galen's comparison to a flute could not be accepted if one were to go into details. He spoke of the vibration of the ligaments, of the dilatations and contractions of the glottis. He asserted that the trachea is elongated in high notes and shortened in low ones. He likened the vocal organ rather *to a horn or trumpet. According to him the glottis is the place which corresponds to the lips of the musician; the body of the instrument extends from the glottis to the external orifice of the vocal canal, that is to say the mouth.*"

Jonathan Wright.

SHORTER ARTICLES.

PREDETERMINED ROOT-HAIR CELLS IN AZOLLA AND OTHER PLANTS.

Ordinary root-hairs arise in acropetal succession in the zone where the surface tissue is becoming fixed; that is to say, in a region at some distance from the root apex, where the cells have ceased to divide and have reached, or are reaching, full elongation. They come from any or all of the superficial cells indif-

ferently. "Only in Lycopodium," says De Bary (*Comparative Anatomy*, p. 60), "can special hair-cells be distinguished from the other epidermal cells of the root."

Special hair-cells are, however, to be found in a considerable range of plants, in which they form a rather striking anatomical character of the epiblema. In all the cases which I have studied, root-hairs arise from cells differentiated for the purpose at a very early stage of the epiblema, and *from no other cells.* The hair-cells are short, often very short, sometimes wedge-shaped, possess peculiarly dense and deep-staining cell contents, and are distributed in a manner determined by the mode of origin. They originate from the division of cells near the root apex. Of each cell pair formed, one becomes a hair-cell and very shortly shows distinctive characters; while the other either becomes a single ordinary, much elongated surface cell, or divides to form several such (hairless) cells. In most cases the cutting off of hair-cells seems to be a matter of stimulus. At times the roots are wholly devoid of hairs and hair mother-cells; at other times the growing conditions—as it would seem—call out these structures.

I find such special hair-cells in *Azolla*, *Isoetes*, *Selaginella*, *Equisetum*, certain Alismales and certain Nymphæaceæ.

In *Azolla pinnata* (the only species examined by me) the root shows several points of interest. The root-cap (as we may call the structure derived from the original segment cut from the outer face of the apical cell) consists of two cell layers, except at the apex, where the inner layer finally undergoes an extra periclinal division. The inner layer for a time coheres closely to the root-trunk, which is thus clothed with a true epidermis. At the same time the outer layer is separated from the inner except at the apex, and forms a distinct root-cap proper. The inner layer is finally pushed away from the root-trunk by the growth of hairs arising from the outer layer of the cortex, so that at maturity, and even before, the main body of the root is quite destitute of an epidermal covering.

The hairs arise in close proximity to the apex. Exterior cortical cells divide by a wall oblique to the external surface. The lower of the two cells so formed in each case almost immediately gives rise to a hair, while the other divides transversely to form two, four or eight hairless cells. At first the hairs stand in regular zones, but ultimately these zones often become more or less broken by the unequal multiplication of the intervening cells in the different vertical rows.

In several species of *Nymphæa* examined the hair mother-cells or the hairs themselves were found as apparently constant characters of the epiblema, alternating very regularly with ordinary cells. In *Nymphæa*, it will be recalled, the root is without epidermis (except root-cap), the epiblema being merely the outermost layer of cortex, the Nymphæaceæ in this respect agreeing with Monocotyledons and certain Pteridophytes. The hair-cells may develop in such a way as to give root-hairs, or they may be—under most conditions they commonly are—suppressed by the closing together, above them, of the ordinary elongated cells. Whenever hairs are found they proceed from short, specialized cells, early distinguishable not far from the growing point. An essentially similar condition is found in *Brasenia*, *Cabomba*, and *Nuphar*.

In some Alismales—*Sagittaria*, *Limnocharis*, *Aponogeton*—essentially the same phenomenon, the production of root-hairs solely from predetermined hair-cells, obtains. This is interesting in view of the recent discovery of the monocotyledonous character of one of the Nymphæaceæ.

I purpose in the near future to describe at length these and other like cases of root-hair formation.

THE AMES BOTANICAL LABORATORY,
NORTH EASTON, MASS.

QUOTATIONS.

SCIENCE AT A WESLEYAN UNIVERSITY.

THE dismissal of Professor Frank D. Tubbs from the chair of natural sciences in Wesleyan University, at Salina, Kansas, throws an interesting light upon the standards of orthodoxy in that State. Professor Tubbs is laboring under the grave charge of believing in evolu-

tion, a theory which the people described as 'the older and more orthodox Methodist ministers' so abominate that they will not even give Professor Tubbs a hearing. Apparently the general issue of academic freedom is not involved here, for the school professes to be a sectarian institution; that is, it subordinates the independent investigation of the truth to the propagation of certain doctrines. Professor Tubbs himself admits that his standing as a scientist, his success as a teacher and administrator, and his character as a man were not the only things considered in his appointment, for he says: "Bishop Vincent fully questioned my beliefs, approved them, and appointed me to the seminary." The only question is whether an evolutionist can be an orthodox Methodist in central Kansas. The trustees of the school say no. The decision may cause Professor Tubbs temporary inconvenience; but if belief in evolution is his only fault, he can comfort himself with the reflection that he is far better off than the 'university' at Salina.—The N. Y. *Evening Post.*

MR. CARNEGIE'S GIFT TO SCOTTISH UNIVERSITIES.

At the time when Mr. Carnegie's gift was first announced, and when nothing had been made known except its magnitude and the fact that it was intended to defray the cost of University education for Scottish students, we felt it necessary to point out, while cordially expressing our admiration of the munificence of the donor, that the very magnitude of the fund would render its wise administration a matter of some difficulty, and to call attention to circumstances which might interfere with the practical realization of the intended benefits. The conditions of the trust, as now disclosed, appear to meet, in almost every particular, the considerations which we mentioned. The application of half the income for the purpose of improving the apparatus of education and for establishing what can hardly fail to become world-renowned laboratories in every department of science which falls within the province of a university will at once lift those of Scotland to the very highest level of academic importance, and will be likely to place the country in the very forefront of practical scientific teaching and investigation. Medical science is specially mentioned in the trust, and, to take only a single example, it will be within the power of the trustees to enable any Scottish University to equip an expedition for inquiring into the life histories of fever-carrying mosquitoes or other insects, and thus to accomplish, perhaps in the course of a few months, more than could be accomplished by private enterprise, aided only by small and laboriously collected donations, even in the course of years. The problems of organic chemistry, again, are daily becoming of more and more importance in relation to health and to disease; as are those of inorganic chemistry in relation to a large number of manufacturing processes or industries. In respect of these and many kindred matters the great hindrance to scientific work in Great Britain has been simply want of means; and this want once removed, a very important step will have been taken towards assisting us to hold our own in the great industrial contests which the future can hardly fail to have in store for us, and in which scientific knowledge will certainly be one of the most important elements of success. We cannot but think that this section of the trust is likely, as time goes on, to prove itself infinitely the more important of the two, and that in the future, under the elastic terms and liberal powers of the deed, it may even come to swallow up or to supersede the general payment of fees which, after all, are not so large as to place a serious impediment in the way of any young man who is not absolutely destitute, and who is determined to push his way to the front of any calling in which it may be his purpose to engage.—The London *Times.*

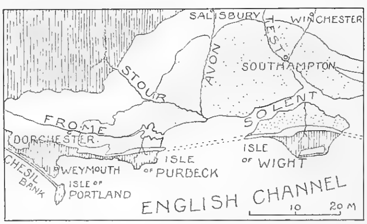
CURRENT NOTES ON PHYSIOGRAPHY.

THE SOUTH COAST OF ENGLAND.

The mid-southern coast of England is bordered by a narrow anticline of mesozoic strata, greatly eroded. The largest remnant of the anticline is the Isle of Wight, while further west a nearly isolated portion is called by the anticipatory name of the Isle of Purbeck. The physical features of the latter, with those of

the associated anticline of Weymouth, are treated in a chapter by Strahan ('The Geology of the Isle of Purbeck and Weymouth,' *Mem. Geol. Sur. England*, 1898, pp. 230–235). Next inland lies the unsymmetrical Hampshire synclinal basin of Tertiary strata, broadening eastward, and thus analogous to the London Tertiary basin. Each basin gave rise to an east-flowing axial consequent river, the lower Thames and the Frome; but while the valley of the Thames is still well preserved, the southern side of the original Frome valley has been greatly consumed by the sea. Lateral consequents of good size still come from the north, and one of them, the Stour, rises back of the chalk cuesta; but nearly all the consequents on the south have been shorn off; yet two small ones still remain, one on the Isle of Wight, one on the Isle of Purbeck, and each of these streams, like the Stour, heads back of the chalk, which on the south forms a monoclinal ridge of nearly vertical structure. Much of the original axial consequent has been destroyed; the river now called Frome being only the upper 30 miles of a stream that may originally have had a length of over 100 miles. The Solent estuary, separating the Isle of Wight from the mainland, is taken to be a middle part of the axial consequent, as described by Strahan in an earlier memoir (1896).

The Isle of Portland, south of Weymouth, is a smaller fragment of the devastated anticline, west of the other remnants. It is now connected with the mainland by the famous Chesil bank (*Ibid.*, pp. 203–209), a superb reef of pebbles and sand, 18 miles long, enclosing a shallow lagoon called the Fleet (from Saxon, meaning shallow water) for 12 miles. The exposed (southwest) face of the reef is a steep beach, benched with long, even terraces (locally called 'curbs'), the temporary records of the maxima in an irregular but generally decreasing series of wave efforts; the highest crest of the reef being the work of the master storm of the decade or century. The reef rests on clays which are sometimes exposed on the beach face after storms. Pebbles are abundantly thrown over the crest of the reef during on-shore winter gales; the windows of the nearest houses in Chiswell (where the reef joins the Isle of Portland) must then be boarded up, even though the crest is there 42 feet 9 inches above high-water mark. The reef as a whole must be marching slowly inland (northeast). It may have been formed originally several miles to seaward of its present position. The pebbles are largest at the southeastern end, where the reef is attached to the wasting and beachless cliffs of the Isle of Portland, and finest towards the northwest end, where it approaches but does not reach the Chalk uplands of Brid port; yet the commonest pebbles are not derived from the Portland sandstones, but consist of well-rounded chalk flints; and there are occasional Triassic pebbles, although no Triassic rocks are exposed for some 30 miles to the west. An earlier writer suggested that the movement of pebbles on the beach is from the northwest, and that the largest ones are now at the southeast end because they are most readily carried by storm waves and drift; but this is difficult to believe. Prestwich thought that the movement is to the northwest. Strahan seems to accept the earlier opinion, but concludes that the more persistent movement is only inward (northeast); and that the materials of the reef represent the most durable sweepings of the land area that has hereabouts been destroyed by the sea. Thus explained, it seems probable that the chalk flints and the Triassic pebbles were derived from exposures of these formations somewhere along the original position of the reef, a district now occupied by the northwestern part of the English channel.



Part of southern England, representing the Hampshire syncline and fragments of the adjoining anticline. Chalk, blank; older formations, lined; Tertiary, dotted.

THE ORIGIN OF FIORDS.

O. Nordenskiold contributes some 'Topographisch-geologische Studien in Fjordgebeiten' (*Bull. Geol. Inst. Univ. Upsala*, IV., 1899, pp. 157–226, 1 pl., 14 fig.), based on observations of fiords and on representations of their form by maps, soundings, etc. He finds normal or radial fiords (West Greenland, New Zealand), parallel fiords (Alaska, Patagonia), and combined forms (Norway). Fiords always occur in groups or systems. Their bottom is uneven, with deep basins and shallow swells. They are from 5 to 40 times longer than broad; they are enclosed by steep and high walls of strong rock. Their distribution shows that they stand in some relation to glaciers: glacial erosion of preglacial valleys best accounts for most features.

This inductive study furnishes many excellent descriptions of typical examples and a series of well-supported conclusions as to the prevalent features of fiords. In attempting explanation, the inductive method seems insufficient; a fuller consideration of what might be expected from long-lasting, vigorous glacial erosion is desirable; for unless the forms reasonably deduced from such a consideration match the observed forms, the theory of the glacial origin of fiords would be seriously at fault. It is perhaps because of the greater emphasis here given to the inductive than to the deductive part of the investigation that the discordant depths of confluent fiords are insufficiently explained, and that the important subject of hanging valleys, recently discussed by several observers, here receives no sufficient mention.

VIEWS OF THE COLORADO CAÑON.

'Glimpses of the Grand Cañon of the Colorado,' is the title of a portfolio of 13 colored plates published by Thayer, of Denver, Colo. It may be 'a fact that under certain conditions the cañon presents the marvelous colorings herein reproduced,' but such conditions are altogether exceptional; and the actual colorings under ordinary conditions are so strong and fine that there is no warrant for a resort in all the views to the exaggerated effects of a rare sunset. Not only are the reds too vivid, but the greens are those of a pluvial, not of an arid climate. The colored views of the cañon published by the Detroit Photographic Company from photographs by Jackson are on the whole to be preferred, not only from being more faithful and delicate but as well from being free from the distraction of more or less irrelevant poetical quotations with which the Thayer views are prefaced.

KABA VOLCANO, SUMATRA.

An entertaining account of the ascent of Kaba, a volcano in Sumatra, is given by Hagen ('Eine Besteigung des Vulkans Kaba auf Sumatra,' *Globus*, LXXIX., 1901, 245–250, 267–273). The illustrations from original photographs are remarkably well reproduced and exhibit the crater forms with unusual success. As in the 'curbs' or storm lines on a beach, so here, the existing craters represent the successive weakening maxima in irregular series of eruptions, all the minima being destroyed except the last.

W. M. Davis.

CURRENT NOTES ON METEOROLOGY.

WEATHER AND CROPS IN SAXONY.

An elaborate investigation into the relation of weather conditions and crop yield in Saxony, based on data for the period 1864–1897, leads to rather unsatisfactory results (Grohmann: 'Die phänologischen Beobachtungen der Jahre 1864 bis 1897, und die Ernteerträge im Königreich Sachsen in ihrer Abhängigkeit von den Witterungsverhältnissen,' Chemnitz, 1901). The various districts of Saxony are divided into three groups, and the results for these groups show striking agreement in comparatively few cases only. On the whole, it appears that there is a larger yield of winter grain in warm and dry than in cold and wet years. An influence of weather conditions upon the yield of summer grain cannot be demonstrated in many districts, and the only fact which does come out clearly is that a greater amount of moisture is necessary in order to produce a large crop of summer grain than a large crop of winter grain. In some cases an influence of higher spring temperatures upon the summer crop is indicated. Potatoes succeed best in years with warm summers and normal

precipitation. The smallest crops of beets and cabbages are usually obtained in dry, warm years. The largest crops of clover and grass come in years with excessive precipitation and high temperatures.

RAINFALL AND FORESTS IN INDIA.

AN important publication on Indian forestry has recently been issued, in which certain conclusions as to the climatic influence of forests are set forth. The book is entitled 'Forestry in British India,' and is by Berthold Ribbentrop, late Inspector-General of Forests to the Government of India (Calcutta, 1900). From a recent review of this volume (*Nature*, April 18, pp. 597–601) it appears that while the author does not distinctly maintain that by afforestation the climate might be improved as far as to stop the recurrence of droughts, it is evident that he is rather inclined to that opinion. He does say that "in a warm climate the denudation of a country diminishes its moisture and consequently its fertility." The regulation of surface drainage by forests is clearly pointed out.

PERIODICITY OF SEVERE WINTERS IN ENGLAND.

IN the *Quarterly Journal of the Royal Meteorological Society* for April is a paper by A. E. Watson, entitled 'A Review of Past Severe Winters in England, with Deductions therefrom.' From an examination of the records of the severe winters of the last 300 years, the writer comes to the conclusion that such winters are most frequent in the years with the numbers 0–1 and 4–5. He is also of opinion that the severe winter in the middle of each decade is generally a late one (Jan.–Mar.), while that at the beginning or end of each decade is generally an early one (Nov.–Jan.).

NOTES.

IN 'Hints to Travelers, Scientific and General,' edited for the Council of the Royal Geographical Society by John Coles (8th edition, London, 1901), there is an article by Dr. H. R. Mill on 'Meteorology and Climate,' the object of which is to supply the traveler with instructions to enable him to make use of meteorological instruments, 'and to obtain evidences of the climate of the region which he is passing through by noticing the effects produced on the land, vegetation, etc.'

MCADIE, of San Francisco, contributes a fourth paper on 'Fog Studies on Mount Tamalpais' to the March number of the *Monthly Weather Review*. In this he considers the refraction of sound waves by fog surfaces and the dissipation of fog. Two excellent half-tones accompany the paper.

BEGINNING with 1901 the Royal Observatory of Belgium will issue an *Annuaire météorologique*. Hitherto the *Annuaire* has been concerned with both astronomical and meteorological matters, but in the future the astronomical and meteorological divisions of the Observatory will have separate annual publications. The *Annuaire météorologique* for 1901 contains, among other matters, a sketch of the history of meteorology in Belgium and a review of two old meteorological journals, by J. Vincent; tables of monthly and annual means of the principal meteorological elements at Brussels and at Uccle, based at the former station on observations from 1833 to 1890, and at the latter from 1891 to 1899; and a paper on 'Le Climat de l'Ardenne,' by Lancaster.

R. DEC. WARD.

COLUMBIA UNIVERSITY BIOLOGICAL LECTURES.

FOR some years it has been the custom in Columbia University to have an annual course of public lectures on some biological topic. This year's series, recently completed, consisted of seven lectures on the Protozoa by Dr. Gary N. Calkins, of Columbia University.

The Protozoa, on account of their unicellular character, are of great importance in relation to many questions of general biology and especially physiology. The seven lectures by Dr. Calkins treated not merely the structure of the Protozoa, but their physiology, relations to more complex forms and the economic importance of certain types. The first lecture was a general sketch of the various discoveries which have gradually led to the recognition of the true relationship of Protozoa to Metazoa. This was followed by lectures on the four main types of Protozoa, in which physiology and

ecology of each were discussed as well as the morphology. The lecture on Sporozoa, which included a résumé of the life history of the malaria germ and other disease-producing Protozoa, was of unusual popular interest. In the sixth lecture Dr. Calkins discussed the renewal of vitality through conjugation, and the relation of conjugation to sexual reproduction of the Metazoa. The last lecture was devoted to a study of the Protozoan as a physiological machine, and was based largely upon the experimental work of recent years which has thrown so much light on the so-called 'vital' phenomena.

A point worthy of mention in connection with Dr. Calkins's lectures, since it contributed not a little to the value of the series, was the mode of illustration. For this purpose the stereopticon with microscope attachment was used, and photographic lantern slides, stained preparations and living Protozoa were thrown on the screen. Living Protozoa have often been thus projected, but in this case the highly perfected apparatus used rendered possible their projection on an unusual scale. *Amœba proteus*, for example, appeared five feet long, *Paramœcium aurelia* nearly four feet, so that many structures, nuclei, contractile vacuoles, etc., became plainly visible to a large audience. The stereopticon method proved especially valuable in demonstrating to large audiences the various 'tropisms' the positive and negative reactions, of certain Protozoa to chemical, electrical and other stimuli. By means of a specially devised electrical apparatus the lecturer was enabled to focus the projecting microscope from the lecture table.

Though the subject was a very special one, the mode of presentation and illustration was such as to render it highly interesting to the non-specialist, as was clearly shown by the large attendance at all the lectures.

J. H. McG.

THE BRITISH NATIONAL PHYSICAL LABORATORY.

THE Friday evening discourse at the Royal Institution, on May 24 was devoted to an account of the aims of the National Physical Laboratory, by Mr. R. T. Glazebrook, its principal. According to the London *Times*, Mr. Glazebrook remarked that the idea of a physical laboratory, in which problems bearing at once on science and industry might be solved, was comparatively new; perhaps the first was the Physikalisch-Technische Reichsanstalt, founded in Berlin by the joint labors of Werner von Siemens and von Helmholtz, during the years 1883–87. It was less than ten years ago that Dr. Lodge outlined the scheme of work for such an institution in England, and in 1895 the late Sir Douglas Galton called attention to the question. A petition to Lord Salisbury followed, and as a consequence a Treasury Committee with Lord Rayleigh in the chair was appointed to consider the desirability of establishing a national physical laboratory. This committee examined over 30 witnesses and then reported unanimously, 'That a public institution should be founded for standardizing and verifying instruments, for testing materials and for the determination of physical constants.' It was now realized at any rate by the more enlightened of our leaders of industry that science could help them. This fact, however, had been grasped by too few in England, though our rivals in Germany and America knew it well; and the first aim of the laboratory was to bring its truth home to all, to assist in promoting a union which was certainly necessary if England was to maintain her supremacy in trade and manufacture, to make the forces of science available for the nation, to break down by every possible means the barrier between theory and practice, and to point out plainly the plan which must be followed unless we were prepared to see our rivals take our place. The effect of the close connection between science and industry on German trade might be illustrated, if illustration were wanted, by the history of the aniline dye manufacture and artificial indigo, and by the German scientific apparatus industry, the growth of which had been expressly attributed to the influence of the Reichsanstalt. Mr. Glazebrook proceeded to describe the means at disposal for realizing the aims of the laboratory. It was to be located at Bushey-house, Teddington, Kew Observatory remaining as the

observatory department. Bushey-house, in spite of its aristocratic history, would make an admirable laboratory. The building was very solid and substantial, and there was a good basement under the main central block with a roof of brick groining which afforded a very steady support for the floors above. The lecturer illustrated its plan with a number of slides, and compared it with the Reichsanstalt, which had an available space seven or eight times greater. But size alone was not an unmixed advantage, and personally he would prefer to begin in a small way if only he was in a position to do the work thoroughly. But there was a danger of starvation. Even with all the help the committee got in freedom from rent and taxes, outside repairs, and maintenance, the sum at its disposal was too small; £14,000 would not build and equip the laboratory, and £4,000 a year would not maintain it as it ought to be maintained. In America the Bill for the establishment of a laboratory which had just been passed authorized an outlay of £60,000 on buildings and site and an annual expenditure of £9,000. Was there no one who, realizing the importance of the alliance between science and industry, would come forward with more ample funds to start the laboratory with a fair prospect of success? Was there no statesman who could grasp the position and see that with double the income the chances of doing a great work would increase a hundred-fold? Give the institution means to employ the best men and it would answer the difficult problems it had to solve; starve it, and then quote its failure showing the usefulness of science applied to industry. In the concluding part of his lecture Mr. Glazebrook gave an account first of some problems of industry which had already been solved by the application of science, *e. g.*, glass for optical purposes, and then of some others which still remained unsolved and which the laboratory hoped to attack, *e. g.*, alloys, wind-pressure on bridges and similar structures, the exact determination of the relations between the scales of the mercury, hydrogen, and electrical resistance thermometers, and the magnetic testing of specimens of iron and steel, besides the standardization and calibration of various scientific instruments.

SCIENTIFIC NOTES AND NEWS.

AT the convocation exercises of the University of Chicago last week, a departure was made, in celebration of the tenth anniversary of the University, from the usual custom of not conferring honorary degrees. The LL.D. degree was conferred on ten men of eminence, including in the sciences, J. H. van't Hoff, professor of physical chemistry in the University of Berlin; Dr. A. Kovalevski, professor of zoology in the University of St. Petersburg; Dr. E. C. Pickering, director of the Harvard College Observatory; Dr. Charles D. Walcott, director of the U. S. Geological Survey, and Dr. E. B. Wilson, professor of zoology in Columbia University.

PROFESSOR A. S. PACKARD, who has held since 1878 the chair of zoology and geology at Brown University, has been elected a foreign member of the Linnean Society of London. The other American members of the society are: Alexander Agassiz, emeritus director of the Museum of Comparative Zoology, Harvard University; W. G. Farlow, professor of cryptogamic botany, Harvard University; D. H. Campbell, professor of botany, Stanford University, and C. O. Whitman, professor of zoology, University of Chicago.

AT its recent commencement Cornell College, Iowa, conferred the degree of LL.D. upon Mr. W J McGee, ethnologist in charge of the Bureau of American Ethnology, Washington. Dr. McGee is of Iowa birth and education, and one of his most important works, a classic in glacial geology, is 'The Pleistocene History of Northeastern Iowa.' The honor thus comes with special propriety from an Iowa school.

M. BERTHELOT (Paris) was elected an honorary member of the Vienna Academy of Sciences on June 1, and the following corresponding members were at the same time elected: Professors Schlegel (Leyden), Oppert (Paris), Linde (Munich), Retzius (Stockholm) and Kovalevski (St. Petersburg).

AT the recent meeting of the Royal Society of Canada, Professor A. B. Macallum, of the University of Toronto, and Mr. Lawrence M. Lamb, of the Geological Survey of Canada,

were elected fellows of Section IV. (Biological and Geological Division).

Sir Robert Stawell Ball, Lowndean professor of astronomy at Cambridge University, will present an address from the University at the bicentennial of Yale University.

Dr. Henry S. Pritchett, president of the Massachusetts Institute of Technology, has been invited to serve as superintendent of awards at the Pan-American Exposition.

Professors Charles O. Townsend and H. P. Gould have resigned from the Maryland Agricultural College, to accept positions in the Bureau of Plant Industry, Department of Agriculture.

Professor E. F. Emery has been appointed special agent of the Bureau of Animal Industry to study the dairy interests in China, Japan and the Philippines.

Dr. P. A. Rydberg, assistant curator at the New York Botanical Gardens, has been given a short leave of absence for a trip in Europe. He will visit the herbaria at Kew, British Museum, Christiania and elsewhere for the purpose of completing some critical studies of the genera in which he is interested, and of arranging for exchanges.

Dr. E. S. Riggs, of the Field Columbian Museum, is now engaged in exploring the fossil beds of Wyoming.

We regret to learn that Professor B. O. Peirce, professor of mathematics and natural philosophy at Harvard University, is still suffering from ill-health, and will probably be unable to resume his university work next year.

Dr. N. S. Shaler, professor of geology at Harvard University and dean of the Lawrence Scientific School, gave the annual address at the commencement exercises of the Worcester Polytechnic Institute.

The Pharmaceutical Society of Great Britain has presented its gold medal to Dr. George Watt, reporter on economic products for the Government of India.

The New York State Pharmaceutical Association has passed a resolution favoring the building of a State laboratory of pharmacy in memory of William Proctor, formerly professor in the Philadelphia College of Pharmacy.

A tablet in memory of Dr. Jesse William Lazear, who lost his life in the study of yellow fever in Cuba, was unveiled at Trinity Hall Military School, Washington, Pa., at its commencement exercises last week.

The Paris correspondent of the London *Times* telegraphs as follows: I have to announce with profound regret the death of one of the most eminent professors of the University of Nancy, M. Bleicher, who has been for six months at the head of the school of pharmacy in that city, after 20 years' service as professor of natural history at the same school. He was murdered by M. Raymond Four, a chemist, a sample of whose cinchona had been seized for analysis at the school, and who, dreading the results of prosecution for fraud, decided to hold the director of the school responsible for his humiliation and mischance. He called yesterday upon M. Bleicher and after a long interview shot him dead and then committed suicide. This monstrous crime has deprived France of one of the scholars who have done most to reveal to the world the geological interest of the frontier provinces of France. M. Bleichers' 'Les Vosges, Le Sol et ses habitants' is a classical treatise which every traveller in Alsace-Lorraine should always carry with him. Every year Professor Bleicher spent his holidays on one or other of the slopes of the Vosges studying the stratifications, the rocks, the glacial marks, all the features, in a word, of this interesting region, upon which he had published a large number of memoirs. He had begun life as Médecin-Major in the French-African army, but left his work there in 1877 to become professor at Nancy, where he was very popular, often conducting students' scientific expeditions. No one so learned was ever more unassuming.

We regret to record the death of T. C. Clarke, which occurred in New York on June 15. Born in 1827, he graduated from Harvard University in 1848, and has been one of the most eminent American engineers, having designed and constructed many American bridges. He had been president of the American Society of

Civil Engineers and had received the Telford Medal of the London Institute of Civil Engineers.

THE death is announced of Mr. William Walton, formerly lecturer in mathematics in Cambridge University and the author of various text-books, at the age of seventy-seven years.

THE first award of the Mackinnon Research Studentship will be made by the Royal Society soon after the first of July. The value of the studentship is £150, and it will this year be awarded in one of the biological sciences.

THE position of aid in the Coast and Geodetic Survey, at a salary of $720 per annum, will be filled by civil service examination on July 23.

AN assistant in entomology in the State Museum at Albany will be selected by civil service examination on or about July 13. The salary, after October 1, will be $720 per annum.

THE New York City Board of Estimate and Apportionment has awarded the contract for completing the New York Public Library building to Norcross Brothers at a cost of $2,865,705.

A SOCIETY has been established in Germany for the study of medicine and the natural sciences, and will hold its first annual meeting at the close of the approaching meeting of German Men of Science and Physicians.

THE Royal Meteorological Society has collected a fund amounting to over £700 as a memorial to the late Mr. G. J. Symons. With this fund a gold medal will be established to be awarded once in two years for distinguished work in meteorology, irrespective of nationality.

THE Peary Arctic Club will send the steamer *Erik* to the North about the middle of July. Mr. Herbert L. Bridgeman will be in charge and Dr. F. A. Cook has accepted the post of surgeon.

PLANS are being made for the establishment of an institute of colonial medicine in Paris, for which about 250,000 francs have been subscribed.

THE Austrian Fishery Association will hold an international fishery exhibition at Vienna during the latter part of September, 1902, a subsidy for this purpose having been granted by the Imperial Department of Agriculture.

AN International Exposition of Hygiene Maritime Security and Fishery will be held at Ostende, Belgium, during August and September. An international congress will be organized in connection with the exposition for the discussion of questions of maritime hygiene and maritime and colonial security.

UNIVERSITY AND EDUCATIONAL NEWS.

MR. JOHN D. ROCKEFELLER has given $250,000 to Cornell University, on condition that an equal amount be contributed by others.

PRESIDENT HENRY MORTON, of the Stevens Institute of Technology, at Hoboken, N. J., has made a further gift of $50,000 for the new chemical building of the institute.

DR. D. K. PEARSONS has made the following conditional gifts: Illinois College, Jacksonville, $50,000; Fargo College, Fargo, N. D., $50,000; Whitman College, Walla Walla, Wash., $50,000; McKendree College, Lebanon Ill., $50,000; Bethany College, Lindsborg, Kans., $25,000; Fairmount College, Wichita, Kans., $25,000; Drury College, Springfield, Mo., $25,000.

AT the recent commencement at Smith College, President Seelye announced a conditional gift of $100,000, one-half for endowment and one-half for the building fund. The condition is that an equal sum must be raised within a year.

MR. J. V. THOMPSON, of Uniontown, Pa., has given $100,000 for the endowment of the president's chair of Washington and Jefferson College.

THE *Experiment Station Record* summarizes the appropriations made recently by State legislatures, according to which it appears that of the exceptionally large appropriations made by Missouri—$467,400 for two years—$40,000 is provided for a horticultural building and the same amount for a dairy and live-stock building. Kansas has appropriated over $200,000 for the biennial period for its agricultural college and station, including $70,000 for a new physics and chemistry building. Minnesota has appropriated $25,000 for a new chemical building and the same amount for a new veterinary building. Washington has appropriated $25,000 for a chemical laboratory. New Hamp-

shire has appropriated $30,000 for an agricultural building.

Among other recent bequests and gifts we note the following: By the will of the late John Sweetser, of Boston, Radcliffe College will ultimately receive $25,000. Mr. George A. Gardner has given $10,000 towards building a laboratory of electrical engineering for the Massachusetts Institute of Technology. Mrs. Maule, of Philadelphia, has given $10,000 to Princeton University to endow a fellowship in biology in memory of her son, F. Hinton Maule. Mr. Irwin Rew, a graduate of the Sheffield Scientific School of Yale University, has made a gift of $10,000 to the school. Mr. G. F. Peabody, of New York, has given to the Georgia State Normal School $3,000 to maintain a department of physiology for two years; he has also made a conditional donation of $10,000 to the school. Dr. Alexander Agassiz has given the School Department of Newport, R. I., $5,000, to be used to equip the biological, chemical and physical laboratories of the Cole School of Science. The trustees of the Mary Hemenway estate have appropriated $500 for an anthropological fellowship in Columbia University.

Two of the three positions offered by the Harvard Medical School to properly qualified men desirous of training in physiological research and in the management of large laboratory classes in experimental physiology are not yet filled for the next collegiate year. Holders of these positions give more than half the day to research. The remaining time is spent during the first four months of the collegiate year in learning laboratory methods and during the last four months in directing the laboratory work of the medical students, about two hundred of whom work from two to three hours daily for sixteen weeks in experimental physiology. The fundamental experiments in physiology done by so many men working at one time present every variety of results and impart a training not to be acquired in other ways. Much too may be learned by association with the large staff engaged in research in the laboratories of anatomy, histology, pathology, pharmacology, hygiene, physiology and physiological chemistry, all of which have their laboratories in the Medical School building. No charge of any kind is made either for the training in physiological research and in teaching or for the use of animals and other material. In addition to these opportunities each assistant receives four hundred dollars. Applications for these positions should be sent to Professor W. T. Porter, Harvard Medical School, 688 Boylston Street, Boston, Massachusetts.

Professor Winslow Upton, director of the Ladd Observatory, of Brown University, has tendered his resignation as dean, owing to ill-health.

W. D. Taylor, formerly head of the department of physics and engineering at the Louisiana State University, has been elected professor of engineering at the University of Wisconsin to succeed the late Professor N. O. Whitney.

Dr. Charles H. Judd will have charge of the department of psychology and pedagogy in the summer school of the University of Cincinnati.

Professor Bruce Fink, of Upper Iowa University, has been elected professor of geology and botany at Drake University, Iowa.

Fellowships in the sciences at Princeton University have been awarded as follows: Mathematics, Oliver D. Kellogg, James C. Moorhead and Adam M. Hiltebeitl; biology, Earl Douglass, Adam M. Miller; astronomy, John M. Poor; mental science, John K. Mackie; experimental science, Claude S. Hudson.

At the University of Wisconsin the following fellowship appointments have been made: Physics, E. R. Walcott; chemistry, H. E. Patten; pharmaceutical chemistry, I. W. Brandell; civil engineering, A. H. Blanchard.

Professor J. G. MacGregor, last year elected professor of physics in the University College, Liverpool, and prior to that professor of Dalhousie College, Halifax, has been appointed professor of natural philosophy at Edinburgh.

Dr. C. v. Kupffer, professor of anatomy and director of the Anatomical Institute of the University at Munich, has retired.

VOL. XIII. NO. 320.

FRIDAY, FEBRUARY 15, 1901.

SINGLE COPIES, 15 CTS.
ANNUAL SUBSCRIPTION, $5.00.

AN "INDISPENSABLE" REFERENCE BOOK.

Vol. III. will be ready very shortly uniform with Vol. I. and II. SOLD ON SUBSCRIPTION ONLY.

Cyclopedia of American Horticulture

Edited by L. H. BAILEY, Professor of Horticulture, Cornell University, Assisted by WILLIAM MILLER, and Many Expert Cultivators and Botanists

Vol. III.
To be Ready very soon.
Cloth, Royal 8vo.

Vol. I. and II.
Each $5.00 *net.*

"The information given is precisely what the horticulturist and general reader is desirous of knowing."
—SCIENTIFIC AMERICAN.

. . . In range, treatment and editing, the Cyclopedia appears to be **emphatically useful: . . . a work worthy of ranking by the side of the Century Dictionary."**—THE NATION.

DESCRIPTIONS OF ALL THE SPECIES OF FRUITS, VEGETABLES, FLOWERS, AND ORNAMENTAL PLANTS IN THE MARKET IN AMERICA AND CANADA. DIRECTIONS FOR THE CULTIVATION OF ALL KINDS OF CROPS, OBSERVATIONS ON MARKETING, ETC.

"A mass of most valuable information, bringing together as it does, into available and properly edited form, the immense contributions of facts from horticulturists to the whole evolutionary doctrine. . . . In short, to such an one [interested in horticulture] the Cyclopedia would seem to be a *sine qua non.*"—*The Dial*, Chicago.

Before you make your garden this spring consult Professor BAILEY'S* GARDEN-MAKING *and* AMATEUR'S PRACTICAL GARDEN BOOK—*or the special books on Vegetable or Fruit Gardening in THE RURAL SCIENCE SERIES or GARDEN CRAFT SERIES—of which circulars will be sent on application to his publishers.

IN THE RURAL SCIENCE SERIES

The latest is by Prof. L. H. BAILEY, of Cornell University. 458 pages, illustrated, indexed for ready reference.

THE PRINCIPLES OF VEGETABLE GARDENING

Just Ready, **$1.25.** The newest and completest book on the subject, and the first to state principles.

PART I.—A general view,—discusses the lay-out, glass houses, etc.,—the soil, tools, seeds, etc.

PART II.—Crops,—takes up root, tuber, bulb, cole, pot-herb, and salad crops; and beans, tomatoes, melons, corn, and others, closing with perennials, such as asparagus and rhubarb. Thorough, but practical.

BOTANY

AN ELEMENTARY TEXT-BOOK FOR SCHOOLS

Half leather.
Illustrated profusely.
$1.10 *net.*

By L. H. BAILEY, Professor of Horticulture, Cornell University, Editor-in-Chief of "The Cyclopedia of American Horticulture," Author of "Lessons from Plants," etc., etc.

"Should be in the hands of every student of Botany. . . . it is marked by a thoroughness and completeness that make it especially valuable.—BOSTON TRANSCRIPT.

"It would be hard to find a better manual for schools or for individual use."—THE OUTLOOK.

"Thoroughly attractive."—THE NATION.

HANDBOOK OF PRACTICAL BOTANY

FOR THE BOTANICAL LABORATORY AND PRIVATE STUDENT. By D. E. STRASBURGER, University of Bonn. Translated and edited by W. HILLHOUSE, University of Birmingham. **$2.60** *net.*

Fifth Edition
rewritten, enlarged.
Fully illustrated.
Cloth, **$2.60** *net.*

"The whole appearance of the work is attractive . . . . Two features are impressed on every chapter of the book (1) definiteness and lucidity of statement, and (2) caution in holding the statements within defensible limits."—EVENING POST, N. Y.

THE MACMILLAN COMPANY, 66 Fifth Ave., New York
